A FRENCH TRIBUTE TO RESEARCH

The President of the French Republic has been pleased to confer upon Sir Henry Wellcome, LL D, F.R.S, la Croix d'Officier de la Légion d'Honneur
This decoration is a further tribute to medical and chemical research to which Sir Henry has made many notable contributions

MARTYRS TO SCIENCE

Forty American radiologists were named in Ham burg, Germany, April 4, among the 165 recorded as heroes of science who sacrificed their lives in medi cal service
In the list the name of Walter J Dodd of Boston appears The names are chiseled on a simple sand stone memorial in front of the Roentgen Institute of St George's Hospital
The names of forty six French and seventeen Ger man scientists are included

LORD HORDER WILL FILL THE POSITION OF
PHYSICIAN IN CHIEF, PRO TEMPORE, AT THE
PETER BENT BRIGHAM HOSPITAL

On the first of May of this year, Lord Horder, Physician in Ordinary to the King and Senior Phy sician at St Bartholomew's Hospital, London, will be at the Peter Bent Brigham Hospital as Physi cian in Chief pro tempore

TUBERCULOSIS IN NEW YORK CITY

Dr John L Rice Health Commissioner of New York City, is quoted in the daily paper as reporting a marked increase in tuberculosis in the city
The number reported for the first quarter of 1936 for New York City is 2,955 as contrasted with 2,568 last year and 2,785 in 1934 The mortality due to tuberculosis has also risen slightly The increased incidence of tuberculosis is ascribed to the effect of the depression

DR. PARRAN HAS BEEN SWORN IN

Dr Thomas Parran, Jr., was sworn in April 6 as Surgeon General of the United States to fill the position made vacant by the resignation of Dr Hugh S. Cumming

CORRESPONDENCE

THE INSPECTION AND REPORT OF FLOODED AREAS IN MASSACHUSETTS

The Commonwealth of Massachusetts
Department of Public Health
State House Boston

April 7 1936

Managing Editor *The New England Journal of Medicine*

A request was made to the United States Public Health Service by His Excellency the Governor asking that a sanitary engineer be sent to make an inspection of the flooded areas and report on the conditions found with reference to health and sanitation. Dr C. C. Applewhite and Sanitary Engineer Arthur P. Miller were assigned to this work. After an inspection of the Merrimack and Connecticut Valleys their report, a copy of which is enclosed was sent to the Surgeon General.

HENRY D. CHADWICK, M.D.,
Commissioner of Public Health

COPY OF THE REPORT

March 26 1936

The Surgeon General
U S Public Health Service
Washington D C
Sir

In compliance with telephonic orders received on March 23 we proceeded immediately in the State of Massachusetts for duty in the flooded areas. Upon arrival in Boston we reported to Dr Chadwick, State Health Commissioner and at his request we made a survey of the Merrimack River Valley with him on March 24. On that date the Merrimack had receded for the most part from the business and residential sections and the work of rehabilitation was progressing satisfactorily in practically all of the areas.

In this survey we confined our attention to those factors which would have a definite bearing on the spread of disease. The most serious situation encountered by us in the Merrimack Valley was found in Lawrence. Here the water filtration plant which is located on the banks of the river and the water pumping station which is adjacent to the filters had been entirely flooded. Fortunately this city's reserve supply of purified water was adequate to maintain a continuity in distribution until arrangements could be made to increase the quantity in storage by borrowing water from three neighboring communities. However as work proceeded in rehabilitating the water purification plant it was soon found necessary to make some curtailment in the use of water in the municipality. These were brought

about, however without seriously inconveniencing the public. With these temporary measures in force exploratory work at the filtration plant continued as rapidly as possible and by March 25 two groups of slow sand filters had been unwatered and it was possible to put decreased quantities through them into the storage reservoir. Every precaution was taken during this period by the State Department of Health through its Division of Engineering to insure that water distributed to the public was satisfactory as to bacteriological quality. The situation at Lawrence can be summed up by saying that water of safe quality is now available to the city although in slightly curtailed quantities.

At Lowell Massachusetts the water purification plant and the pumping station were both put out of commission by flood waters. Fortunately the physical layout of this system was such that the raw water sources which are driven wells near the bank of the river were not seriously affected and an adequate supply was constantly available. Precautions were taken however to disinfect this water at two points in the system, one in the conduit carrying the water to the city and the other at the pumping station located in the city proper. Through these means a continuous supply of pure water was furnished to Lowell at all times and no evidence was available to indicate that any outbreak of water borne diseases would be possible.

In both Lawrence and Lowell the prompt and adequate measures which were put into force by the State Department of Public Health entailing men on duty 24 hours a day assured continuous supplies of water suitable for public use.

After a fairly complete survey of the Merrimack Valley towns affected by the flood it was felt that all measures essential to the protection of the public health were being put into execution in a satisfactory manner.

At the request of Dr Chadwick we proceeded to the flooded area in the Connecticut Valley on March 5. The following towns were visited in company with a member of the staff of the State Department of Public Health, Springfield Holyoke Northampton, Hntfield Deerfield, Chicopee.

Upon our arrival in Springfield it was learned that all of the public water supplies in the Connecticut Valley which might have been adversely affected had already been adequately safeguarded as a result of the alertness and vigilance of the District Engineer in that territory. In this area a survey was made of the facilities for caring for those evicted from the flood area and the measures which were being put into execution for the purpose of reclaiming the flooded area.

Most of the towns had adequate physical facilities for taking care of those who were removed from the flooded area in school houses and other public buildings. A detailed inspection of a school thus utilized at Springfield was made. At this school about 800 people were being housed and fed. The sanitary conditions at the time of inspection were beyond criticism and the precautions taken for protecting

the people against the dangers incident to overcrowding were considered adequate, and in all the towns visited there was no report of an increase in the number of communicable diseases

The sections of all municipalities, which had been flooded, were protected by the National Guard and police to prevent looting. Just as rapidly as the water receded, inspections of the homes were being made by the police and Health Departments to determine the safety of the dwellings for occupancy. The task of ridding the dwellings, stores, streets, and sidewalks of mud, slime, and debris deposited by the flood is large and time-consuming. However, this material which will have to be removed in order to make the places fit for human habitation is of no consequence so far as disease causation is concerned. In most of the towns, considerable progress has already been made in this cleanup campaign.

Having in mind the emergency conditions, which obtained in each of these stricken valleys, both of us were of the opinion that satisfactory provisions had been made to guard against the spread of communicable diseases and that those engaged in efforts toward this end should be commended for promptly initiating and executing the measures essential to safeguarding the public health.

C C APPLEWHITE, *Surgeon,*

ARTHUR P MILLER, *Sanitary Engineer*

RECENT DEATHS

McEVoy—THOMAS EDWARD McEVoy, M.D. of 769 Main Street, Worcester, Massachusetts, died in that city, March 28, 1936.

Dr McEvoy was born in 1859 and educated in the public schools of Hopkinton, Massachusetts, Exeter Academy and Yale. He graduated from the Yale Medical School in 1892, served his internship in the Bridgeport City Hospital, later being associated with the teaching staff of the Lying In Hospital of New York City.

Soon after settling in Worcester in 1896, he was appointed a member of the staff of St Vincent's Hospital and served in that capacity until about five years ago when he became consultant.

His widow, Mrs Mary W (Spencer) O'Day-McEvoy, a son, Thomas S McEvoy, and a step-daughter, Miss Marion T O'Day, survive him.

CURTIS—FRANCIS GEORGE CURTIS, M.D., of Ashfield, Massachusetts, died at his summer home there, April 7, 1936.

Dr Curtis was born in Staten Island, New York, in 1857, graduated from Harvard College in 1879 and from the College of Physicians and Surgeons of New York in 1883. He had practiced in Newton, Mass., until twenty years ago and had been the Chairman of the Newton Board of Health for forty two years, resigning this position last July because of ill health.

Dr Curtis joined the Massachusetts Medical Society in 1887 and was also a Fellow of the American Medical Association, a member of the Newton Medical Club, the Staff of the Newton Hospital and one of the founders of the Massachusetts Association of Boards of Health and had served as president of this last named organization.

He is survived by his widow, Mrs Ruth Curtis, and three sons, Mr George Curtis, Mr Shaw Curtis, and Mr Edward Curtis.

DAVENPORT—FRANCIS HENRY DAVENPORT, M.D., a retired physician of Boston, died April 9, 1936, at the Hotel Puritan. Dr Davenport was born in Roxbury in 1851, graduated from Williams College and later received his M.D. degree from the Harvard Medical School in 1874. After postgraduate courses in Vienna and other medical centers, he returned to Boston and was an instructor in gynecology at Harvard with an affiliation at the Massachusetts General Hospital. Dr Davenport joined the Massachusetts Medical Society in 1877 and retired in 1935. He was a member of the Harvard and the Williams Clubs and the Gynecological Society of America.

A son, Henry Davenport, survives him. His wife died in 1905.

NORTON—EBEN CARVER NORTON, M.D., of North Chatham, Massachusetts, died at his home, April 11, 1936, after an extended illness. Dr Norton was born in 1856 at Vinai Haven, Maine, the son of Jesse and Hannah Carver Norton. He was a graduate of Harvard College and of the University of Vermont Medical School.

Dr Norton was credited as the founder of the Norwood Hospital for mentally ill patients. His previous experience in psychiatry was at the State Hospital at Tewksbury and in association with Dr Walter Channing.

He moved to North Chatham in 1928. He was a Fellow of the Massachusetts Medical Society and the American Medical Association.

A son, E Lawrence Norton, of Salt Lake City, Utah, and three daughters, Miss Helen Norton of Chatham, Mrs Howard E Whipple of Richmond, Virginia, and Mrs Gregg Smith of Long Beach, California, survive him.

KNIGHT—CHARLES STORER KNIGHT, M.D., died in Portland, Maine, April 12, 1936, following a recent operation in Boston.

Dr Knight was born in Portland, Maine, and after his preliminary education in Portland schools and Westbrook Seminary, entered the Harvard Medical School and graduated in 1896.

He was a former house physician at the Boston City and the Boston Lying In Hospitals and at one time was assistant superintendent of the Boston City Hospital. He was a Fellow of the Massachusetts Medical Society from 1896 to 1905.

NOTICES

THE HENRY JACKSON LECTURES OFFERED BY THE NEW ENGLAND HEART ASSOCIATION

These lectures will be given by Tinsley R. Harrison, M.D., Associate Professor of Medicine Vanderbilt University School of Medicine, at 4 45 P.M. on Thursday April 30 and Friday May 1, at the Boston Medical Library (John Ware Hall)

Subjects

1. The Pathogenesis of Circulatory Failure
2. The Principles of Therapy in Patients with Congestive Heart Failure

Physicians and students of medicine are cordially invited to attend.

The annual business meeting of the New England Heart Association will precede the lecture on April 30

ANNUAL TUFTS ALUMNI ADDRESS

Dr William B Keeler Class of 1903 Health Commissioner for the City of Boston, will deliver the annual alumni address to the students of Tufts College Medical School, Wednesday April 29 at four o'clock in the amphitheater at the school 416 Hunt Avenue. The subject of his address will be "Preventive Medicine and Public Health. The alumni faculty and friends of the school are cordially invited to attend.

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P.M. on Thursday April 23 in the Amphitheatre of the Peter Bent Brigham Hospital Dr Henry A. Christian, Physician-in-Chief, Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School will give a medical clinic. To it are cordially invited practitioners and medical students

On Saturdays in the wards of the Peter Bent Brigham Hospital from 10 to 12 staff rounds will be conducted by Dr Christian.

THE GEORGE WASHINGTON GAY LECTURE

Dr W Dacre Walker a graduate of Tufts College Medical School in 1905 will give the George Washington Gay Lecture on Wednesday April 22 at four o'clock in the amphitheatre at Tufts College Medical School. Dr Walker has chosen as his subject "What the Small Town Doctor Does.

The George Washington Gay Lectureship Fund was originally established in 1926 with a gift from Dr George W Gay of Chestnut Hill Massachusetts for lectures at the Tufts College Medical School upon Medical Ethics and the Art and Practice of Medicine

FIRST INTERNATIONAL CONGRESS OF SANATORIA AND PRIVATE NURSING HOMES

The First International Congress of Sanatoria and Private Nursing Homes will be held in Budapest at the end of September next. Special invitations will be sent in due course to all parties concerned. Lectures discussions proposals etc., should be sent to the following address as early as possible in order that they may be included in the official program. Committee of the First International Congress of Sanatoria and Private Nursing Homes Budapest Margitiziget, Sanatorium

PHYSICIANS ART EXHIBITION

The Physicians Art Society will hold its annual exhibition April 29-May 9 at Doll & Richards Galleries at 138 Newbury Street, Boston.

All members of the Massachusetts Medical Society who do painting and sculpture are cordially invited to join the Society and show examples of their work at the coming exhibition

Application should be made to James F Ballard at 8 Fenway Boston.

CLOVER HILL HOSPITAL Lawrence, Mass.

The next speaker in the Clover Hill Hospital series of monthly medical lectures will be Donald Munro M.D. Visiting Surgeon for Neurosurgery to Boston City Hospital. His subject is The General Practitioner's Relation to the Problem of Brain and Skull Injuries.

Date Thursday April 23 1936 at 8 30 P.M. His talk will be illustrated.

All physicians of Greater Lawrence are invited to attend.

NICANDRO F DeCESARE, M.D., Chairman.

REPORTS AND NOTICES OF MEETINGS

NATIONAL HEALTH COUNCIL ANNUAL MEETING

The annual meeting of the National Health Council, held in New York City on February 6 was of unusual interest this year because of the election of new officers and the discussion of a series of problems of significance in national health conservation

The Nominating Committee reported that it found it necessary to relieve Colonel Roosevelt from the Presidency because of business professional and national public services which precluded continuance of his administrative duties in connection with the Council. Expressing regret that such action had become necessary the Committee recorded its recognition and deep appreciation of the services Colonel Roosevelt had rendered the Council and its satisfaction in reporting that he would continue as a member at large of the Board of Directors

The Nominating Committee then recommended the election of Dr Donald B Armstrong, as President, for the year 1936, pointing out that he had been an active officer and executive in promoting the Council's development, and had made the final study of all the voluntary agencies which led to its organization in 1920. In addition to Dr Armstrong's intimate knowledge of all the member agencies and their respective fields of activity, it was recognized that his training and experience in scientific, medical and public health work constituted exceptional qualifications. The Council unanimously approved his selection for the presidency.

For Vice-President, Mr T N Pfeiffer, an attorney, the present incumbent, and widely known for his promotion of social work activities, was nominated.

For Treasurer, Mr Frederick Osborn, likewise the present incumbent, and a leader in population studies, and other fields of science and welfare, was nominated.

For Secretary, Professor Maurice A Bigelow, a noted educator and biologist and Professor in Columbia University, was nominated.

These general officers were unanimously elected.

For membership in the Board of Directors ten members at large were nominated, representing public health administration, education and research, as well as eleven direct representatives of the member agencies of the Council. The following is a list of these directors, as unanimously elected.

Dr R M Atwater, American Public Health Association

Colonel H E Bullis, National Committee for Mental Hygiene

Mr L H Carris, National Society for the Prevention of Blindness

Miss Dorothy Deming, National Organization for Public Health Nursing

Mr Howard Green, National Committee of Health Council Executives

Dr Kendall Emerson, National Tuberculosis Association

Dr C C Little, American Society for the Control of Cancer

Dr H M Marvin, American Heart Association

Dr S H Osborn, Conference of State and Provincial Health Authorities of North America.

Dr William F Snow, American Social Hygiene Association

Dr F N Sperry, American Society for the Hard of Hearing

AT LARGE

Dr George Baehr, New York Academy of Medicine

Dr S J Ciumbine, Formerly American Child Health Association

Dr H S Cumming, U S Public Health Service

Dr William De Kleine, American Red Cross

Dr Louis I Dublin, American Public Health Association

Livingston Farrand, President, Cornell University

Mr Homer Folks, New York State Charities Aid Association

Dr A S Knight, National Committee for Mental Hygiene

Colonel Theodore Roosevelt

Ray Lyman Wilbur, President, Stanford University

HARVARD MEDICAL SOCIETY

The Harvard Medical Society met at the Peter Bent Brigham Hospital Feb 11, 1936, Dr Elliott P Joslin presiding.

The medical case was presented by Dr G L Sullivan, Jr. A fifty-three year old, Russian housewife entered the hospital Jan 17, 1936, complaining of a dry mouth and throat of a few days' duration. Eight years ago she suffered easy fatigue and loss of weight, and was found to have diabetes mellitus, for which she was given insulin and dietary régime. For the past two years she had not used insulin. For the past three weeks she had noticed increasing thirst, and for four days before entry had experienced increasing loss of strength and appetite, with some nausea. On the day of entry there was vomiting.

Physical examination showed a dehydrated, middle-aged woman with an odor of acetone on her breath. There was auricular fibrillation. Examination of the urine showed a trace of albumin, and positive tests for sugar and acetone. Her blood sugar on entry was 433 mg per cent. The blood urea nitrogen was 21 mg per cent and the CO₂ combining power 22 vol per cent. She was placed on the usual diabetic régime, and recovered from her acidosis in satisfactory manner. She had had a continually elevated temperature since admission, which was believed to be due to urinary tract infection, since there were numerous white blood cells found in her urine. X-ray studies of the chest were negative. She required 45 units of insulin before breakfast and 10 units at noon and evening to keep her urine free of sugar. It was decided to try the effect of the new insulin protamine, and she was given 20 units that evening.

Dr Fitz remarked that she had auricular fibrillation on entry, and that as soon as her acidotic state had been corrected her heart had become regular. He asked if such observations were usual. Dr Howard F Root of the Joslin Clinic replied that one similar case had been seen at the Deaconess Hospital.

Dr Elliott P Joslin remarked that, of a series of 176 diabetics on whom postmortem studies had been performed, 18 per cent had been found to have active inflammatory disease of the urinary tract. He also stated that insulin protamine required two or three days to exert its full effect.

The second case was presented by Dr Robert Bates of the surgical service. A twenty-seven year old white housewife entered the hospital with the history of pleurisy on the right side four years ago, since which time she had noted easy fatigue,

general weakness and diarrhea of severity sufficient to necessitate eight or nine movements each day. Eight months previously her sister died with tuberculosis, and x-ray studies performed on the patient revealed bilateral apical tuberculous lesions. She was hospitalized at Middlesex Sanatorium at that time where she remained until she was transferred to the Brigham Hospital. One month previous to admission she developed an increasing severity of diarrhea, and x-ray studies revealed marked contraction of the colon. She was transferred to the Brigham Hospital for operation. Physical and laboratory studies were not remarkable. Under spinal anesthesia the terminal ileum cecum and ascending colon were resected for tuberculous colitis. Her postoperative course was uneventful.

Dr John Homans stated that this was an ideal case for resection of the colon. He believes that more cases of tuberculous colitis should be operated upon if localization of the disease process can be established.

Dr Merrill C. Soeman demonstrated the pre-operative x-rays of the case, and pointed out that the bowel was not only markedly constricted in diameter but that it had also greatly decreased in length due to shrinkage, a feature characteristic of tuberculous colitis. The bowel distal to the lesion was shown to be dilated by the barium enema, a feature which Dr Soeman stated was observed whenever pressure had to be used to force barium through an obstructing lesion, and which was not due to any intrinsic disease in the distended bowel.

The paper of the evening was presented by Dr C. N. H. Long of the University of Pennsylvania, who spoke on "The Effect of Hypophysectomy and Adrenalectomy upon Experimental Diabetes in the Cat." The removal of all insulin by pancreatectomy gives rise to a series of events:

- (1) Hyperglycemia and glycosuria appear and persist even during fasting.
- (2) There is an increase in nitrogen excretion and there is a definite ratio between the amounts of glucose and nitrogen excreted ("D/N ratio").
- (3) Large quantities of acetone bodies appear in the urine.
- (4) Finally acidosis develops, coma intervenes and death occurs.

These facts are established, but the mechanism of the observed events has proved the subject of much controversy. One group holds that the loss of insulin from the body results in an inability of the tissues to utilize carbohydrates and as a result fats and lipids are drawn upon to furnish body energy. The incomplete oxidation of these substances in the absence of carbohydrate utilization liberates ketone bodies which give rise to the symptoms of acidosis. They believe that there is a definite ratio between the utilization of fat and glucose the so-called ketogenic/antiketogenic ratio.

The second school of thought is known as the

overproduction theory of diabetes. Their original theory postulated that the removal of the pancreas precipitated a glandular imbalance between the thyroid and adrenal medulla, the secretions of the two glands acting in such manner as to cause an overproduction of glucose from fat and protein. This overproduction was so great as to cause hyperglycemia and glycosuria and was supposed to take place in the liver. It was believed that the tissues maintained their normal ability to utilize carbohydrate in spite of the absence of insulin. This original theory has not been supported by experimental data, and it has been shown that the body loses its ability to use glucose in the absence of insulin.

Both theories, however, maintain that sugar can be formed from protein by the liver (gluconeogenesis).

A large percentage of individuals dying from diabetes have no demonstrable pathology of the pancreas. Certain patients with abnormalities of other glands are frequently known to show glycosuria, or frank diabetes. Thus glycosuria is observed in some 75 per cent of acromegalics. Cases with increased activity of the adrenal cortex (tumor or hyperplasia) often exhibit glycosuria. These latter cases also exhibit a hyperplasia and hyalinization of the basophilic elements of the anterior pituitary.

The close psychological relationship between the pituitary and adrenal cortex is interesting. Removal of the pituitary causes a shrinkage of the adrenal cortex, with a condensation of the reticular zone and a decrease in the amount of lipid material in the zona glomerulosa. If anterior pituitary extract is supplied, these changes disappear and the gland returns to normal appearance.

Houssay somewhat elucidated the disturbances in carbohydrate metabolism observed in diseases of the anterior pituitary. Removal of the hypophysis was found to prolong the life of depancreatized animals and to lower the D/N ratio. Acidosis and ketosis did not appear in these animals, and if fasted they often became sugar free. (Thus the D/N ratio disappeared.) Injections of crude extracts of the anterior pituitary accentuated the glycosuria, ketonuria, and ketosis.

These depancreatized hypophysectomized animals alternate between hypo- and hyperglycemia. When they are extremely emaciated and their fasting blood sugar is low administration of intravenous glucose solution is followed by a variation in blood sugar level which is almost identical with a normal blood sugar tolerance curve. If however the animals have a high blood sugar level or are on the usual protein fat low carbohydrate diet, administration of glucose results in a typical diabetic blood sugar curve. The R.Q. of these animals increases only very slightly showing that there is no great increase in the utilization of carbohydrates. Similar results are obtained in depancreatized adrenalectomized animals. It is concluded that neither

hypophysectomy nor adrenalectomy has any pronounced effect in increasing carbohydrate utilization except in emaciated animals with low blood sugar

There is a marked effect of hypophysectomy on the duration of life and on the fat metabolism of depancreatized animals. The usual life of a depancreatized cat is about five days, and death occurs following extreme hyperglycemia and acetoneuria. Depancreatized, hypophysectomized animals have an average life of forty-nine days, their blood sugar is maintained at a lower level and there is a marked decrease in the excretion of glucose, nitrogen and acetone bodies. Thus the chief effect of hypophysectomy seems to be to decrease the production of glucose from protein and the prevention of acidosis. (The marked fall of basal metabolic rate following ablation of the pituitary must not be forgotten, however.)

Removal of the thymus gland had little effect on depancreatized animals. Thyroidectomy, although not increasing the duration of life, or lowering the blood or urine sugar, did decrease acetoneuria.

The effect of adrenalectomy on depancreatized animals was studied by Dr Long and his associates. Removal or denervation of the medulla had no effect in protecting against glycosuria. Removal of both adrenals and the pancreas increased the duration of life, and lowered the excretion of glucose, nitrogen, and acetone bodies. These animals were maintained on large doses of cortical extract. It thus appears that adrenalectomy has an effect similar to that observed after hypophysectomy, although the former animals must be maintained on doses of cortical extract. Hypophysectomized animals do exhibit an atrophy of certain elements of the adrenal cortex, however.

A comparison of the livers of depancreatized animals with or without adrenalectomy shows that there is a greater store of glycogen in the former. The liver fatty acids are usually increased from six to twenty-five per cent following pancreatectomy, an increase which is prevented by removal of the adrenals or hypophyses.

It is important to note that the adrenalectomized animals were maintained on large doses of cortical extract, and that their sodium metabolism was not disturbed. Evidently some cortical principle other than those contained in the extracts used was removed by adrenalectomy. It is possible that the adrenal acts through the pituitary in some way, and that removal of the cortical material produces an effect because of changes in the pituitary secretion.

Injections of potent anterior pituitary extracts were made into depancreatized animals in which the first group had been subjected to hypophysectomy and the second group to adrenalectomy. The injections into the hypophysectomized animals caused the reappearance of glycosuria, ketonuria and acidosis but had no effect on the adrenalectomized animals. The specific adrenotropic prin-

ciple of the pituitary likewise had no effect on the second group of animals, but increased the glucose, but not the acetone body excretion of the first group.

Dr Long concluded by stating that although the evidence is suggestive, it is by no means conclusive that there is a diabetogenic hormone in the adrenal cortex. Hypophysectomy and adrenalectomy are valuable procedures for the experimental study of diabetes, but they should not be considered as therapeutic measures to be employed in the treatment of the disease.

THE NEW ENGLAND HOSPITAL ASSOCIATION

The New England Hospital Association held its fourteenth meeting February 27, 28 and 29 at the Hotel Statler, Boston. A most interesting program had been arranged.

Mrs B B Marble, Secretary of the American Dietetic Association and Research Dietitian of the Collis P Huntington Hospital, Boston, presented a very well edited history of the growth of the national dietetic association. She carefully traced the gradual increase in the importance of the dietitian's functions as the physician's ally in the treatment of diseases and the continuance of investigative work.

Quindara Oliver Dodge, Associate Professor of Institutional Management, Simmons College, Boston, gave a concise discourse on the need and functions of a capable and well trained manager for the various necessary maintenance services of a hospital.

Thursday afternoon was devoted to the questions which arise in hospitals relative to their training schools. Sister Francis James, St Mary's Hospital, Waterbury, Conn, presented the educational features available in a well conducted Out Patient Department. Miss Elizabeth E Sullivan, R N, Supervisor of Schools of Nursing of the Massachusetts State Board of Registration of Nurses, Boston, presented the difficulties which are besetting the various hospitals conducting Training Schools for Nurses, and the present educational facilities which exist. Ann Wolf, R.N., Director of School of Nursing and Nursing Service, New York Hospital, New York City, gave a concise report of the activities of the Education Committee of the National League of Nursing Education in their efforts to increase and unify the standards which should be accepted as approved training for the profession of nursing. Miss Wolf traced the development of the Committee's work since 1917, calling special attention to the increased demands for a more general and thorough education of nurses.

Friday morning Miss Eleanor Jones, President of the Massachusetts State Association of Record Librarians, Newton Hospital, Newton, gave a short paper on the wishes which all record librarians in hospitals have respecting their work. It seems that the lack of cooperation of the medical staffs of the various hospitals and the failure of a standard classification of diagnoses cause most of their troubles.

Miss Ruth Tartakoff, Supervisor of the Admitting Office, New Haven Hospital, New Haven, Conn., and Miss Mary H. Roberts, Director of Social Service, Holyoke Hospital, Holyoke, Mass., discussed the need of trained Social Service workers in hospitals as aids to physicians in the care of patients.

Friday afternoon was devoted to a thorough discussion of Group Hospitalization and the prepayment plans for hospital services. Mr. Graham Davis of the Duke Foundation, Charlotte, North Carolina, presented the state-wide development of prepayment plans in North Carolina in comparison with those in Great Britain. Mr. Frank Van Dyk, Executive Director of the Associated Hospital Service of New York, gave a clear discussion of the plan which has been in operation in New York for the past nine months. Of 57,000 subscribers in New York, nearly 2,000 have had hospital service in nine months. These people have expressed their satisfaction with the plan. In the discussion which followed the presentation of these papers, definite statements were made that physicians in these communities are having better collections of accounts than before the hospitalization plans went into effect.

A most interesting development at the annual meeting was the establishment of a section for Trustees of Hospitals. Eighty-three trustees were in attendance and discussed their various problems in providing adequate hospital care for the patients.

During the meeting the Massachusetts members of the Association organized a State Association, the object of which is to promote the effectiveness of hospitals in Massachusetts.

Papers by Dr. Willinsky and Dr. Faxon were read and are appended.

THE MASSACHUSETTS STATE HEALTH SURVEY

BY CHARLES F. WILLINSKY, M.D.,

*Deputy Health Commissioner, City of Boston
Executive Director, Beth Israel Hospital*

Late in November of 1934, shortly following the election of His Excellency, Governor Curley, a special committee was appointed by the Massachusetts Central Health Council to consider a study of the Public Health practices and a revision of the Public Health laws of Massachusetts. This committee had in mind a similar study conducted in the State of New York by a special Health Commission appointed in 1930 by President Roosevelt, who was at that time Governor of the Empire State. The conclusions and recommendations of the New York Commission proved of great value in raising the Public Health standards and practices in that state.

The hope was expressed at the meeting of the special committee of the Central Health Council that His Excellency, the Governor might favor the legislative action necessary for the appointment of a Commission by the Governor for the study and

revision of our Public Health laws. In view of the fact that the New York study was financed in the main by the Milbank Fund, it was suggested that an effort ought to be made to obtain necessary funds for the proposed Massachusetts study from a private foundation. Dr. Willinsky agreed that, should there be a favorable reaction on the part of the Governor, he would approach the Commonwealth Fund of New York for the required funds.

His Excellency the Governor was most interested in this proposed study and embodied in his inaugural address this statement:

The Commonwealth of Massachusetts has always maintained an enlightened interest in matters pertaining to the health of its citizens. It has been expeditious from time to time to establish and maintain essential service, and to enact or amend laws for enlarging the scope of those departments created for the prevention of disease since they affect the very lives of our people and should be administered with the highest possible degree of efficiency. I have received assurances that in the event of the appointment of a commission for the study and revision of the public health laws of the Commonwealth, a national foundation interested in public health will defray the expenses of the commission and subject to favorable action by your Honorable Body I shall appoint such a commission."

Dr. Willinsky and Professor Wilson Smith called on the Commonwealth Fund and secured from its representatives the assurance of their willingness to finance this project subject to the approval of the Board of Directors of the Fund. In April of 1935 the Board approved the grant of \$10,000 for the financing of the proposed study.

The following resolve was introduced into the Legislature and passed:

"Resolved That an unpaid special commission consisting of the commissioner of public health and the commissioner of mental diseases ex officio, and ten other members to be appointed by the governor is hereby established for the purpose of studying and investigating the public health laws and policies of the Commonwealth. After completing said study and investigation but not later than the first Wednesday in December in the current year said commission shall report to the general court by filing with the clerk of the House of Representatives the results of its study and investigation with its recommendations if any as to what changes it deems necessary in such laws and policies together with drafts of such legislation as may be necessary to carry such recommendations into effect.

This resolve was passed in May 1935 resulting in the appointment by His Excellency the Governor of the following Commission:

Professor Curtis M. Hilliard—President, Massachusetts Health Council, Professor Biology and Public Health, Simmons College

Professor Wilson G. Smillie—Professor, Public Health Administration, Harvard School of Public Health

Dr. Alexander Begg—Dean, Boston University School of Medicine, Acting Secretary,* Massachusetts Medical Society

Professor Samuel C. Prescott—Dean of Science and Professor of Industrial Biology, Massachusetts Institute of Technology

Dr. Dwight O'Hara—Chairman, Public Health Committee, Massachusetts Medical Society, Professor of Preventive Medicine, Tufts College Medical School

Dr. David Scannell—Chief of Surgical Service and President of Senior Staff, Boston City Hospital

Dr. Francis X. Mahoney†—Health Commissioner, City of Boston

Dr. Charles F. Wilinsky—Deputy Health Commissioner, City of Boston, Executive Director, Beth Israel Hospital

Dr. Gerardo Balboni—Physician, Home for Italian Children, Member of staff of Massachusetts General Hospital.

Dr. Charles E. Mongan—President, Massachusetts Medical Society

After its appointment, the Commission met and elected these officers:

Dr. Henry D. Chadwick, Chairman

Dr. Wilson G. Smillie, Vice-Chairman

Dr. Charles F. Wilinsky, Secretary-Treasurer

The Commission set up fourteen committees to investigate major Public Health problems and procedures. Over one hundred men and women, leaders in their fields are engaged in the study of the following topics:

- 1 Transference of vital statistics to the official health agency
- 2 Formulation by the State Department of Public Health of statewide quarantine requirements
- 3 Transference of municipal and county tuberculosis hospitals to the State
- 4 Suitable standards for public health personnel
- 5 The development of measures which may serve to take public health more nearly out of the field of politics
- 6 Development of a more effective program for the control of gonorrhea and syphilis
- 7 The development of adequate resources for rural communities, commensurate with their ability to pay
- 8 Development of adult hygiene
- 9 Better coordination of the school health services
- 10 Formulation of reasonable laws for the suppression of rabies
- 11 Formulation of a program for the reduction of maternal mortality

12 Development of more effective health standards for industry

13 The licensing of hospitals

Of particular interest to hospitals are these subjects:

- 1 Licensing of hospitals
- 2 Who is responsible for the payment of bills incurred in the care of the indigent in time of sickness in hospitals and in the home, also bills for the care of the injured in accidents, i.e., auto accidents
- 3 Abuse of hospital charity, question of legislation making it a misdemeanor to obtain such under false pretense
- 4 Responsibility of public health agencies for preventive medicine
- 5 Statistics
- 6 Miscellaneous—are there other subjects for consideration?

A number of the appointed committees have already submitted their reports to the Commission. Others are still working in subcommittees on various aspects of their particular studies.

There can be no question that the ultimate recommendations of the Commission will do much to strengthen Public Health work in Massachusetts and consequently to improve the health and well-being of the inhabitants of the state.

HOSPITAL COUNCILS*

BY NATHANIEL W. FAXON, M.D.,

*Director, Massachusetts General Hospital and
Massachusetts Eye and Ear Infirmary*

Hospital Councils have developed from Superintendents' Councils or Clubs or other unofficial groups. The first Hospital Council, as such, that I know of was the Cleveland Hospital Council, established in 1915. The success of this Council and the very evident need of such organizations led to the formation of other Councils throughout the country. Some of these Councils were formally incorporated, included practically all the hospitals of the city as members, were intimately associated with health and welfare organizations and took an active part in community life. Others were small, in formal gatherings of hospital superintendents who met to exchange information on matters of internal administration.

The American Hospital Association, believing that Hospital Councils were destined to play a part in the growth and development of hospitals from a community standpoint and in their relationship to Health and Welfare Departments, recommended, in 1932, that it be a subject for consideration by the Council on Community Relations and Administrative Practice (as it was then called). Since then the Council has made several reports upon the number, formation and accomplishments of Hospital

In June 1935 elected as Secretary
†Died January 14, 1936

*Presented at the meeting of the New England Hospital Association, February 28, 1936, Hotel Statler, Boston.

Councils and has offered suggestions regarding the formation of Councils.

Although many and varied types of Hospital Councils have been found to exist, it can definitely be stated that their functions fall into two groups

- A. Cooperation among hospitals in dealing with common problems of internal administration
- B. Coordination of hospitals in action on community relations

Under the first group A, the following activities appear

- (a) Promotion of uniform statistics and accounting
- (b) Collection and dissemination of information cost of supplies wages
- (c) Collection and dissemination of information concerning rates
- (d) Cooperative purchasing
- (e) Cooperative action in collecting
- (f) Development of common standards of admission to wards and Out Patient Departments

Under the second group B there develops common action

- (a) In relation to legislation
- (b) In relation to publicity
- (c) In relation with other agencies e.g. with the medical profession, local tax appropriating bodies, other governmental departments industrial or insurance agencies.
- (d) Common action in establishing Group Hospitalization.
- (e) Relations with fundraising organizations
- (f) Coordination with hospitals in other communities in the same region.
- (g) Participation in community hospital and health surveys
- (h) Participation with other community groups in dealing with questions of the amount and distribution of hospitals and outpatient facilities size and location of new hospitals and proposed additions

These items of course do not cover all the fields of activity but are set down merely to indicate what Hospital Councils have already taken up advantageously

I want to call your attention particularly to this last function because in the opinion of some who have given thought to these matters this will ultimately prove to be the most important activity of Hospital Councils. We are supposed to be living in a civilized community and civilization in one sense consists in giving up voluntarily some of your rights in order that you may live peacefully with your neighbor he of course doing likewise. Now what is applicable to individuals should also apply to institutions for instance to hospitals. None of us as individuals or as we represent institutions are willing to sacrifice all our autonomy nor is it

needful that we must recognize that there is a community welfare as clearly as there is a personal or institutional welfare. In every city there can be pointed out the mistakes in hospital building that have been made because the viewpoint and welfare of the community have been sacrificed to the ideas and plans of the individual organization or institution. From this formation of Hospital Councils the American Hospital Association has hoped to promote the consideration of hospital problems upon the broad basis of the welfare of the community.

The American Hospital Association Council also recommended that the term Hospital Council should be applied to an organization only when it included representatives of hospital departments other than the administration, as for instance Trustees, Staff and others, and also representatives of community interests. For organizations consisting only of Hospital Superintendents the term Superintendents Conference was recommended. Where a number of small communities covering a considerable area had formed a joint organization having the same purposes as a Hospital Council that it be called a "District Association". The latest report of the Committee 1935 shows

- 24 Local Hospital Councils
- 13 Superintendents Conferences
- 7 Regional or District Associations

These are all active organizations. Undoubtedly there are many more informal groups

The Hospital Council of Boston was formed January 30 1935 by action of twenty three Boston hospitals. For many years there had been an informal Hospital Superintendents Club but it was evident that a more formal organization was necessary—one which should include other community elements and which could represent the hospitals in relationship to the Health League Council of Social Agencies and the Community Federation.

The object of the Hospital Council of Boston is to promote intelligent planning and coordination in the field of community hospital service to serve as a forum for the discussion of common problems and as a clearing house for the exchange of information looking to the advancement of service to interpret to the public functions of hospitals and their place in the community to cooperate with other agencies concerned with health and social problems and such other business as may properly come before the Hospital Council."

Each member hospital was to have three representatives, a Trustee the Superintendent, and—this was an unusual feature—a representative of the medical staff. Besides this representation from member hospitals there were also representatives from the Massachusetts Medical Society the Dental Society the Nurses Association and five persons representing the public at large.

A close tie-up with the Boston Health League and the Council of Social Agencies was effected. The Executive Secretary of the Health League was made Executive Secretary of the Hospital Council,

giving half time to each position. These three agencies occupy adjoining offices with many services and activities in common. This is economical and keeps the different organizations accurately informed of what the others are doing and so avoids wasteful duplication and loss of time.

It is hard to evaluate the Council as yet, it is too young. Perhaps if we look back over some of the items set down as proper functions for a Hospital Council and see how many we can check off, we may get some idea of the activities of the Boston Hospital Council during its first year.

Under those functions listed as coöperation among hospitals in dealing with common problems of internal administration we find the following:

- (a) Uniform accounting and reporting undertaken to assist relations with the Community Fund and Federation.
- (b) A start upon the subject of common rates and charges, through the appointment of a committee to cooperate with the Massachusetts Medical Society in adjusting Workmen's Compensation rates with the Insurance Companies and the Industrial Commission.
- (c) Consideration by the Executive Committee of common standards for out patient admissions, though it is only fair to state that nothing much has been accomplished yet.

Under those functions listed as coördination of hospitals in action on community relations, the following:

- (a) Legislation. Just at present this item has occupied our attention almost to the exclusion of all others. Opposition to Bills requiring open staffs, Bills stipulating procedures in surgical operations, Bills taxing hospital property and others have kept the Executive Committee busy. They have also sponsored the introduction of two Bills—one an amendment to the labor law requiring weekly payment of wages, which would exempt hospitals and also a Bill sanctioning the incorporation of nonprofit hospital service corporations for the providing of hospital insurance to groups. In appearing before legislative committees it is a real help to be able to say that you are representing twenty-three hospitals which form the Boston Hospital Council. That represents votes and compels attention.
- (d) Group hospital insurance. A committee is working on this. They have submitted a Bill, House 573. Ask your Representatives and Senators to support it. This applies to all hospitals in Massachusetts.
- (e) Relations with the Community Federation are close and friendly. It is a help to both groups to have a central organization where many problems may be thrashed out in general terms before being taken to the individual unit for final consideration.

- (g) Participation in surveys. These are with us always and the Council acts as a central clearing house in evaluating and collecting data. The one-day census taken under the direction of the Council was well done and the report, which will soon be published, will provide valuable factual data.

So you see we have made some progress. The adoption of uniform accounting and reporting of statistics to the Community Federation, the fostering of friendly relations with the Medical Society, the making of common endeavor with them on WCA problems, the beginning on Group Hospitalization Insurance, the opposing of dangerous legislation and the support of desirable bills have kept the Officers and Executive Committee very busy.

All in all, I think we can say that the Boston Hospital Council has helped. It has offered an organization through which Boston Hospitals may discuss, reach conclusions, and present their views in an effective manner. It forms a rallying and representative point. This is valuable and helpful. What the future will bring only time can tell.

BOSTON SOCIETY OF BIOLOGISTS

The February meeting of the Boston Society of Biologists was held at the Harvard Biological Laboratories in Cambridge, February 26, 1936. Dr. M. G. Banus spoke on The Final Tension in Isometric Muscular Contraction in Relation to Initial Tension and Length. By means of a special apparatus and careful measurements he was able successfully to separate the factors of tension and length in the isolated striated muscle. The final tension plotted against the initial stretch is a straight line function, but if the initial tension instead of the final tension is plotted, a curved line results. This was found to be true in several different striated muscles. Dr. Banus concluded that the final tension is a straight line function of the length of the fibre.

Dr. T. L. McMeekin spoke on Certain Solubility Relations of the Amino Acids and Their Derivatives. By neutralizing the different groups in the amino acids and studying the solubilities of the resulting compounds in water and alcohol, the effect of the neutralized groups was studied. The CH_3 group has a much smaller effect on solubility when it is between two polar groups than when it is a terminal group. The solubility in alcohol becomes greater when the chain of CH_2 groups attached to the carboxyl group becomes longer. When the NH_2 group is removed, the compound becomes less soluble in water and more soluble in alcohol. The effect is the same in all the mono-amino acids. These solubility tables are of great assistance in separating the amino acids and their derivatives.

Dr. H. L. Fevold spoke on the Augmentation of the Gonad Stimulating Action of Pituitary Extracts by Copper Salts. The follicle stimulating hormone of the pituitary stimulates the ovarian follicles to grow. The luteinizing hormone does not increase

the weight of the immature ovary when given alone, but when combined with the follicle stimulating hormone causes greater ovarian development than does the follicle stimulating hormone alone and both follicles and corpora lutea develop. Thus there is a synergistic action of the two hormones.

Yeast extract and yeast ash increase the gonadotropic action of the follicle-stimulating hormone and also of follicle-stimulating hormone plus luteinizing hormone. Copper salts and zinc salts also produce increased responses but copper salts are more effective than those of zinc. Neither the yeast preparations nor the salts alter the qualitative ovarian response to the gonadotropic preparations.

Zinc salts probably bring about their effect by decreasing the rate of absorption of the active material but the effect produced by the copper salts cannot be explained on this basis. In normal immature rats, copper salts increase the action of both follicle-stimulating hormone and follicle-stimulating plus luteinizing hormone, but in hypophysectomized rats they increase the action of follicle-stimulating hormone alone. Zinc salts produce the augmentation of both types of gonadotropic preparations in normal and in hypophysectomized rats. Copper salts also produce ovulation in rabbits while zinc salts do not. For these reasons it is assumed that the copper acts as a catalyst between the follicle-stimulating hormone and the luteinizing hormone. Thus if there is no hypophysis, there is presumably no luteinizing hormone in the blood with which the follicle-stimulating hormone can react. However when the follicle-stimulating hormone and luteinizing hormone are injected together with copper into hypophysectomized rats, augmentation takes place as in the normal animals.

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held Monday April 27 at 8 15 P.M., at the Boston Dispensary 26 Bennet Street. Program 1. The Significance of a Prominent S-Wave in Lead II of the Human Electrocardiogram Dr George Ravit. 2. Observations on Shock and Collapse Dr S J Thannhauser. 3. Unexplained High Basal Metabolism Rates in Heart Disease Without Failure, Dr Heinz Magendanz. 4. Clinical Observations on the Treatment of Angina Pectoris Dr Joseph H. Pratt. 5. Some Effects of Diet Restriction on the Circulation in Patients with Heart Disease. Dr Samuel H. Proger.

All members of the New England Heart Association and interested physicians are invited to attend.

JAMES M. FAULKNER, M.D., Secretary

NEW ENGLAND SOCIETY OF PSYCHIATRY

The Annual Meeting of the New England Society of Psychiatry will be held at the Gardner State Hospital, East Gardner Massachusetts Wednesday April 22, 1936.

The speaker will be Dr A. Myerson, Professor

of Neurology Tufts College Medical School Clinical Professor of Psychiatry Harvard University Medical School whose subject will be "The Neuroses".

HANLEY L. PAINE, M.D., Secretary-Treasurer

THE AMERICAN ASSOCIATION FOR THE STUDY AND CONTROL OF RHEUMATIC DISEASES

The American Association for the Study and Control of Rheumatic Diseases will hold its fifth conference on rheumatic diseases at the Phillips Hotel third floor on May 11, at 9 o'clock in Kansas City.

The tentative program appears below

An Educational Program of the Differential Diagnosis of Diseases of Joints

- 1 Clinical Grouping and Diagnostic Approach to the Patient with Joint Conditions Dr Russell Haden.
- 2 Differential Diagnosis of Joint Diseases from the Standpoint of Pathology Dr Edwin P. Jordan.
- 3 The Essential Features in Differential Diagnosis of Atrophic and Hypertrophic Arthritis Dr Ralph Boots.
- 4 Differential Diagnosis between Strumpell Marie Disease and Osteoarthritis of the Spine Dr Joseph L. Miller.
- 5 Differential Diagnostic Points of Gonorrheal Arthritis Dr Stafford Warren.
- 6 Differential Diagnostic Points of Tubercular Arthritis Especially Tubercular Polyarthritis Dr Frank D. Dickson.
- 7 Differential Diagnostic Points of Rheumatic Fever Dr Ralph A. Kinsehl.
- 8 Differential Diagnostic Facts about Gout, Distinguishing It from Other Joint Diseases Dr Philip S. Hench.
- 9 Differential Diagnosis of Traumatic Arthritis Dr Willis Campbell.
- 10 Differential Diagnosis of Fibrositis Dr C. H. Slocumb.
- 11 Differential Diagnostic Points of Constitutional Conditions Mistaken for Arthritis Which Produce Skeletal Aches and Pains Dr Will Ham J. Kerr.

THE AMERICAN NEISSERIAN MEDICAL SOCIETY

The American Neisserian Medical Society will hold its second annual meeting on May 18 1936 in the Hotel Staller Boston, Massachusetts. All who are interested are cordially invited.

PROGRAM

- 10 00 A.M. The Flow of the Seed in Antiquity M. L. Brodny M.D., Boston
- The Technique of Isolating the Gonococcus and of Determining the Thermal Death Time C. M. Carpenter M.D., Rochester
- The Application of the Thermal Death Time

consists of a long, laced leather cuff applied to the arm from the upper deltoid region to just above the elbow and connected by a hinge with a similar cuff on the forearm. If there is a wrist drop from radial nerve injury, a light aluminum cockup splint to the hand is provided, attached to the forearm cuff. The patient is then instructed to use the arm in as nearly normal a manner as possible. The actual degree of function obtained by the use of this apparatus is quite striking as compared with the former marked limitation of arm activity. The previously wasted muscles regain power, circulation is greatly improved and by x-ray there is a progressive decrease of the bone atrophy. The length of time that the splint is worn is determined by the original condition, by the rapidity of improvement in the functional appearance and by the x-ray evidence of diminishing bone atrophy. The average duration in these cases was five months.

We wish to emphasize, however, that in the above patients nonunion had been present from one and one-half to three years and that these individuals had all previously submitted to surgery on the humerus. One patient had three operations, another two, and two patients had one unsuccessful operation to secure union of the fracture. In each instance our roentgenograms revealed pronounced bone atrophy of the fragments. There was evident circulatory disturbance in the extremity as well as advanced muscle wasting. Slight to moderate loss of radial nerve cutaneous sensation was noted in three patients, associated with weakness in the extensor muscles of the forearm.

This particular group of patients would obviously require a relatively long interval of preoperative care. In cases seen earlier, however, without previous operation, and in whom bone atrophy, muscle weakness and local circulatory insufficiency were not so marked, it was evident that the preoperative treatment would be of shorter duration than is here reported.

BLOOD CHEMISTRY

In all patients exhaustive blood chemistry studies were done with repeated estimations (in operated cases) of the blood calcium, phosphorus, and phosphatase. With one exception the findings were normal. The "product" of calcium phosphorus determinations was not significant. In one patient, Case 5, the blood phosphorus averaged 1 to 12 milligrams on four examinations. This value is lower than the average blood phosphorus estimation (25 to 40 mgm per 100 cc blood). Therefore phosphorus, in the form of dibasic calcium phosphate, was administered by mouth for five months, when the blood phosphorus averaged 3 to 44 milligrams per 100 cc of blood.

DIET

All patients were given a high vitamin, high protein diet with adequate calcium and phosphorus bearing food. The obese patients were reduced, and cases of malnutrition advised a high caloric intake. The bowel function was supervised and in fact every effort made to improve the patient's physical and mental status. In each instance the individual's general condition at the time of operation was decidedly better than when first seen.

THE ONLAY GRAFT WITH METAL SCREW FIXATION

Sever sums up the requirements for treatment of nonunion in fractures of the humerus when he states that the operative repair must provide primary internal, as well as secondary external fixation for a long period. This author also remarks that external fixation is never complete in any apparatus.

We feel that primary *internal fixation* by autogenous bone graft is especially important. In our hands, such fixation is best secured by the use of the massive onlay graft held by metal screws. While two of the cases in this series were successfully treated by the inlay graft technique, the degree of primary internal fixation obtained by us through this method, does not compare with the firm fixation secured through use of the onlay graft. Furthermore, in patients with nonunion of the humerus a "carpenter's fit" for the inlay graft is difficult to obtain in the slender, atrophied fragments and yet not injure the adjacent thin margins of humeral bone.

The reader is referred to the articles by Mitchell, Henderson and by Campbell for a detailed description of the general technique of application of the massive onlay graft. The significant modification in our hands is the use of metal screws to fix the graft.

The technic of looped chromic catgut sutures (Mitchell) to hold the graft in place has not, in our opinion, provided sufficiently firm internal fixation for nonunion of the humerus. In the sclerotic and atrophic humerus we have found that beef bone (Henderson) or autogenous screws or nails (Campbell) do not hold so firmly as a self-tapping metal machine screw (Sherman). Furthermore, bone screws are rather friable and may break off when partly inserted. Finally, we believe that the use of taps and dies to make autogenous bone screws while ideal is not satisfactory because of the time consumed and because of the fragility of normal human bone.

The advantages, therefore, of metal screw fixation of the massive onlay graft may be briefly summarized as (1) the simplicity and ease of application of the graft as compared with the use of beef bone screws or autogenous bone nails.

or screws, (2) the very firm internal fixation we cured resulting in close contact between graft and fragments, and (3) with the use of metal screws a corps of assistants is not necessary.

The presumed disadvantage of metal screws is that as a foreign body they might prevent bone union, or later becoming loose have to be removed. But in the two cases so treated there was no evidence of delay in bone union as the x rays revealed advanced callus formation within three months' time (figure 3c). Over an interval of two years and sixteen months respectively, the roentgenograms do not exhibit any signs of bone reaction or absorption about the metal screws (figures 4 and 10).

Metal screws and nails have been, and are of course now, repeatedly utilized by surgeons for fixation of loose bone fragments. In the absence of bone reaction there is a difference of opinion as to whether the metal should be removed. Ashurst, for example, reports patients in whom metal screws or nails remained twenty years without ill-effect. In the cases here reported removal of the metal screws is a simple procedure. All patients are warned that this may be necessary but only in the event of local symptoms or of x ray signs of bone reaction about the screws. We conclude, therefore, that the available evidence does not contraindicate the use of metal screws to hold an onlay graft applied for nonunion of the humerus.

ACCESSORY CHIP AND SPLINTER GRAFTS

In addition to the massive onlay graft it is also most important to surround the fracture site with splinter and chip grafts of cortical and particularly of cancellous bone (figures 3b and 11) likewise removed from the tibia preferably from near the epiphyseal line. The square surface of raw bone is thereby greatly increased and in addition a large local supply of calcium is available so that the probability of bony union is still further assured.

NONUNION WITH INFECTION

In patients with nonunion of the humerus following fracture and associated with infection the bone graft operation as herein described is not undertaken until one year after the closure of all wounds, particularly in the presence of considerable scar formation. When the time for operation is determined the procedure is divided into two stages. The scar is first excised and if this operation is not too extensive the bone fragments are also prepared for the graft and the wound then closed. If the immediate post-operative course is uneventful the wound is then reopened in fourteen to twenty-one days and the onlay graft applied.

In this type of case, that is, where there has been infection, Phemister reports that if the in-

fection can be sufficiently well localized, and hence probably avoided at operation, much time and disability may be saved by the use of the onlay splint graft. The latter is not fastened to the humerus but simply placed on the two fragments, with the fracture area as the mid point. To succeed in such an operative attack, in the absence of any internal fixation, it is additionally required that the bone fragments be held in relatively good alignment and position by preëxistent callus or scar.

OTHER METHODS

The following brief statements summarize our views on other commonly employed methods of bone grafting.

The intramedullary peg graft is decidedly not satisfactory for treatment of nonunion of the humerus.

The osteoperiosteal graft alone is not adequate chiefly because of lack of internal fixation. Thus we believe to be true even if step cutting and suturing of fragments are performed. Such a graft may often be advantageously employed as an accessory aid to bone union, or, in those instances where immediate fixation by the graft is not necessary, that is, when the alignment and approximation of fragments is acceptable and fixation is secured by a combination of preëxistent callus plus the externally applied apparatus.

The sliding bone graft appears preferable to the above two methods, but because of the atrophic and often sclerotic bone necessarily utilized, we do not believe that this procedure is as effective as a massive onlay graft from the tibia.

We have had no experience with ivory plates or pegs.

Steel plating in these cases is unwise, while silver wire is to be condemned.

COMMENTS ON THE OPERATIVE TECHNIQUE OF ONLAY GRAFT WITH METAL SCREW FIXATION

It is decidedly advantageous to apply a snug body cast with shoulder straps two days before operation. Following application of the bone graft a close fitting arm plaster, extending from the proximal hand to shoulder, is then attached to the body cast. This cast is worn until roentgenograms exhibit bone union—an average of three to five months. If the cast is applied in the manner described it is possible to obtain the maximum degree of firm, postoperative external fixation. Such immobilization is essential to secure healing of the fracture.

The skin incision should be ample so that there is no trauma to the soft parts from retraction. The exposure of the humeral shaft (figure 12) as described by Henry affords easy access to the bone with minimal bleeding and complete protection of the radial nerve.

The periosteum of the humerus is incised and

gently separated over an area sufficient only to admit placing the graft directly on the humerus. In this connection we have not found clinical evidence that the periosteum alone is of osteogenetic significance. However, the periosteum is vitally important in maintaining bone circulation as emphasized by Gallie and Robertson.

As Henderson suggests, the eburnated ends of the bone fragments are easily prepared by a transverse saw cut, thus removing the greater part of the sclerotic bone. Drilling (with a 1/4 inch bit) of the medullary canal may also be done.

The bone bed in the fragments upon which the graft is to lie is most simply fashioned by using a broad osteotome and removing a thin layer of cortex down to bleeding bone (figure 13).

The average size of the onlay graft in these cases is one-half inch wide, six inches long and in thickness the depth of the tibial cortex down to the medullary canal. The necessity of a large graft cannot be too strongly emphasized. The graft is easily removed from the tibia by motor saw and chisel.

The bone fragments then are aligned and the graft held in place by an assistant. Holes are drilled through the graft and the superior cortex of the humerus with a special bit measuring one thirty-second of an inch less in diameter than the diameter of the metal screws (9/64 of an inch). The latter are the self-tapping vanadium machine screws devised by Sherman. When finally in place, the screws pass through the graft and *both* cortices of the humerus (figure 13). The resulting fixation is so firm that the extremity feels like the normal arm.

After placing multiple bone chips and splinter grafts about the fracture, the wound is closed in layers and the plaster spica completed.

CONCLUSIONS

1 Nonunion in shaft fracture of the humerus most frequently occurs in the mid-third and junction of the mid and distal third of the humeral shaft.

2 Of the various factors which may cause nonunion we are impressed by (1) early operation, that is, performed at the time of or shortly after the fracture and (2) faulty fracture immobilization.

3 To obtain bone union the importance of adequate preoperative care is emphasized. Such a régime is directed toward improving arm circulation, to overcoming muscle weakness and to diminishing the atrophy of the bone fragments. This is accomplished by instructing the patient to wear an arm splint designed to immobilize the unstable fragments of the humerus and so permit relatively normal arm function. As ex-

plained in the text the length of time the splint is worn is an individual problem. With nonunion of long duration and the consequent marked atrophy of bone and soft parts, as in the patients here reported, the preoperative care averaged five months. In addition every effort is made to improve the patient's general physical and mental status through proper diet, rest and good hygiene.

4 In our opinion the most satisfactory operative procedure in these cases is that of the massive onlay graft with metal screw fixation. The use of metal screws greatly simplifies this operation. The case histories of two patients treated by this method are reported in detail. In both instances a good result was obtained.

CASE 1. Mrs. N. B., housewife, aged twenty-nine years, was admitted to the Clinic on August 30, 1932 for treatment of nonunion of a fracture of the left humerus.

In April, 1931 the patient was in an automobile accident and sustained a simple comminuted and spiral type of fracture of the shaft of the humerus at the junction of the middle and lower third. Immediate wrist drop and loss of sensation over the dorsum of the hand and forearm were reported. This condition gradually improved by slow progressive stages so that on admission to the Clinic there remained superficial anesthesia of the dorsal forefinger, together with moderate weakness of the extensor muscles, thumb and distal forearm. Within three hours after the injury open reduction was performed elsewhere. Apparently the fragments were sutured with catgut. The arm was then held in a metal splint for four weeks. One year after the injury, also elsewhere, an intramedullary bone peg graft was inserted between the humeral fragments. The patient was immobilized six weeks. Nonunion persisted.

On admission to the Clinic there was obvious complete instability of the humerus (figure 1).

FIGURE 1 Case 1—Admission photograph. Note scar of previous operations and that to raise arm it must be supported.

Range of wrist motion was normal, but there was definite weakness in the grasp of the hand.

The x-rays (figure 2) revealed marked generalized atrophy of the bone of the humerus and sclerosis of the ends of the fragments. No attempt at bone repair appeared. The only laboratory note of significance was a blood phosphorus of 13 milligrams. All other findings were normal. The general health of the patient was excellent, although she was somewhat overweight.

a

b

Preoperative Treatment Carried out as described above. Dibasic calcium phosphate by mouth raised the blood phosphorus at the end of four months to an average level of 3 to 3.4 milligrams. A leather arm splint permitted active function of the extremity so that at the end of five months there was marked improvement in the circulation and muscle development in the arm while bone atrophy was appreciably less.

Operation On January 23 1933 an inlay graft of bone removed from the tibia was done splinter and chip grafts placed about the fracture line and the arm then immobilized in a plaster spica. May 8 1933 Five months postoperative roentgenograms showed maintenance of alignment of the fragments and apparent early healing of the fracture. On July 28 1933 further x rays revealed fracture of the bone graft. The position of the humeral fragments was unchanged. Plaster cast support was therefore continued. But on October 25 1933 ten months following the operation, while the graft had united to the proximal fragment of humerus there was definite absorption of the graft at the site of fracture and complete failure of bone union of the humerus.

February 10 1934 a second operation consisting of application of a massive inlay graft with metal screw fixation was done. Multiple chip and splinter grafts were also placed about the site of the fracture (figure 3). The arm was immobilized in a plaster spica for five months. Union was obviously underway in the fourth month and five months following the operation the fracture had completely healed. The patient regained normal function of the extremity within one month from this time and since then has continued to use the arm in a normal manner.

FIGURE 3 Case 1—*a*—X-rays taken just before the second operation consisting of the application of a massive onlay graft. Note slight lateral bowing of proximal fragment of humerus due to angle of union of part of inlay graft.

To prevent excessive shortening of the humerus it was decided preoperatively to accept this deformity. It was thought that with bone union obtained continued bone growth would tend to correct this angulation progressively (compare figure 5)

FIGURE 5: a, b Case 1—Two year follow up. No symptoms. Normal function of the arm. Note comparison of arms reveal no deformity

Summary of Case 1 Ununited fracture of three years duration in a twenty nine year old housewife and located at the junction of the middle and lower thirds of the shaft of the left humerus. Two previous operations before admission to the Clinic. An additional attempt by us to obtain union with an inlay graft was unsuccessful. This graft fractured during the sixth postoperative month and was in greater part absorbed by the tenth month after the operation. The patient was re-operated on February 10 1934 with application of massive onlay graft held by metal screw fixation together with multiple chip and splinter grafts placed about fracture line. Union was obtained.

Follow-Up Two years after the operation there is normal function of the arm, while the roentgenograms reveal no evidence of reaction about the metal screws. The patient carries on her usual activities.

CASE 2. Mr. A. H., student, aged twenty years, was admitted to the Clinic March 24 1934 for treatment of nonunion of fracture of the middle third of the shaft of the right humerus.

The patient fell from a ladder and fractured the humerus one and one-half years before admission. A closed reduction was twice attempted elsewhere but the fracture did not heal. Six months later also elsewhere, a bone graft from the tibia was applied (the exact type of procedure not known) but nonunion persisted.

Examination revealed an ununited fracture at the middle third of the shaft of the right humerus with complete flail motion. The x rays (figure 6) exhibit

pronounced generalized atrophy of the fragments of the humerus and the usual sclerosis at the end of the fragments. The third fragment was considered to be probably part of a bone graft from the previous operation. As seen in figure 7 there was

a

b

FIGURE 9 a, b—Case 2—Sixteen months follow up Normal arm function, no symptoms. Compare with figure 7

marked muscle atrophy of the extremity, the circulation was inadequate and disability complete. General physical examination and a detailed blood study was in no sense remarkable except that the patient was rather slender and apparently somewhat under weight.

Preoperative Treatment The patient was placed on the régime as described. He wore the supporting arm brace for six months (figure 8) at the end of which time his general condition was considerably improved. The musculature of the arm was then decidedly stronger while the circulation was comparable to that of the uninjured arm. In addition the roentgenograms revealed a generalized increase in density throughout the shaft of the humerus.

On October 19, 1934 an onlay graft with metal

screw fixation was applied together with multiple chip and splinter grafts about the site of the fracture. The extremity was then immobilized in a plaster spica.

Postoperative Course In the third month the roentgenograms showed evidence of beginning callus formation which was sufficiently advanced in the fourth month, so that the arm was removed from the plaster spica. On clinical and x-ray examination there was firm union of the fracture. The patient rapidly regained normal function of the extremity (figure 9).

Follow-Up February 19 1936 sixteen months after operation x-rays (figure 10) show a healed frac-

a

b

THE HEART IN CHRONIC GLOMERULAR NEPHRITIS*

BY ARTHUR B. RICHTER, M.D.,† AND JAMES P. O'HARE, M.D.†

WHILE most of our profession now appreciate the importance of the extrarenal elements in one form of Bright's Disease—chronic vascular nephritis—there are many who still regard glomerular nephritis solely as a disease of the kidneys. The first in a series of papers on this form of nephritis¹ pointed out that the eyeground changes found in glomerular nephritis are vascular in origin and that they are essentially the same lesions as those found in nonrenal vascular hypertension. Another paper, to be published later, will show that a significant number of patients with this type of nephritis die from causes other than their renal insufficiency. This paper is a study of the part played by the heart in chronic glomerular nephritis.

While the literature fairly teems with reports on the hypertensive heart there is a great paucity of writing on the cardiac changes in glomerular nephritis *per se*. To be sure, all textbooks refer to its hypertension and cardiac hypertrophy and the ominous significance of uremic pericarditis. Special articles are, however, few indeed and concerned chiefly with special phases of the subject. Barach² and Pyrah³ write specifically of pericarditis. Wood and White⁴ and Schwab and Herrmann⁵ in their respective articles disagree on the interpretation

of the electrocardiograph changes found in uremia.

Such a scarcity of reports is easy to understand. In the first place, in acute nephritis the heart is a matter of concern only in the very rare patient in whom hypertensive crises or convulsive seizures bring about congestive failure. Then again in the entire group of patients with cardiac involvement the number of cases of chronic glomerular nephritis is, after all, relatively small. Finally most authors assume—perhaps correctly—that the heart in chronic glomerular nephritis is merely the ordinary hypertensive heart. Our chief purpose in making this report is the twofold one of remedying this lack of established data in the literature and of adding to the existing knowledge of pericarditis in nephritis.

A Renal Clinic in existence for eighteen years has given us an unusual opportunity to follow a fairly large group of these patients through out a large part of their illness. Our report is based on a study of all patients with significant chronic glomerular nephritis who have come to autopsy at the Peter Bent Brigham Hospital from its opening in 1913 to the beginning of the year 1935. From a total of seventy-five such cases five have been excluded for complicating cardiac valvular disease and four because they were examples of that unusual and complicated syndrome described by Libman and Sachs⁶, Tiemann⁷ and Christian⁸ of long continued fever with inflammatory changes in serous and synovial membranes, subsequent glomerular nephritis and chronic fibrous pericarditis.

*From the Medical Clinic of the Peter Bent Brigham Hospital, Boston.

This is the third in a series of papers on Chronic Glomerular Nephritis.

†Richter Arthur B.—Assistant Resident Physician Peter Bent Brigham Hospital 1935. O'Hare James P.—Senior Associate in Medicine Peter Bent Brigham Hospital. For records and addresses of authors see This Week's Issue, page 849.

Of the remaining sixty six patients, forty one were males and twenty five females, varying in age when first seen, from 2 6² to sixty two years. One-third of our sixty six patients were observed periodically from one to ten years. Another third were followed from one to twelve months. Observation in the remainder was limited to a brief but variable period antedating death.

It is obvious that in nephritis as in any other chronic disease death may occur not from the primary disease but from related or wholly unrelated causes. This was so in seven of our patients who died not from uremia but from such extraneous causes as cardiac failure, cerebral hemorrhage, pneumonia, etc., with renal function still adequate. In these seven the final blood urea nitrogens averaged 37 mgm. per cent. In the remaining fifty nine patients, death occurred in uremia with renal insufficiency practically complete. In them the blood urea nitrogens reached a terminal level averaging 172 mgm. per cent.

In the entire group of sixty six hypertensions of moderate or severe grade (average 200/120) was present in all but five. The low pressures in the latter number are easily accounted for by the fact that they were seen only a few days before death and no doubt their pressures represented merely the prelethal fall.

SYMPTOMS

It is well known that most patients with a chronic glomerular nephritis have few or no complaints until the process is far advanced. This is particularly true of the cardiac phase of the disease. Occasionally one does see a patient in whom cardiovascular lesions outstrip the renal disease. In such a patient cardiac problems may appear early and play a predominant role.

While cardiac disturbances of one kind or another developed in every one of our patients, the time of onset, the type and the severity varied considerably. Complaints about the heart were rarely encountered until one year before death with the exception of certain significant differences that did occasionally occur. These will be discussed later. The cardiac symptoms and signs differ but little from those seen in primary hypertension.

Easy fatigue and flatulence possibly of cardiac origin, occurred frequently and early but these symptoms as well as the palpitation and vague apical discomfort, which were less often and more tardily noted, were difficult to evaluate. The two outstanding symptoms were pain and dyspnea and these rarely occurred until one year before death.

Cardiac pain apart from vague and insignificant apical distress was uncommon and when

present was due either to coronary artery disease or to pericarditis. Angina pectoris was a symptom in only one patient and typical coronary thrombosis likewise occurred in but a single patient a lad of twenty eight. This is a much lower incidence than in primary hypertension in which the age of the patient is greater and the arterial disease is usually of longer duration and of greater severity.

Uremic pericarditis, occurring in 44 per cent of our sixty six patients, was a more common cause of precordial discomfort. In sixteen patients it took the form of precordial distress or oppression but in five it was described as severe pain. In eight patients in whom a rub was heard the patient was unaware of any cardiac difficulty. In two cases the precordial pain associated with slight fever leucocytosis, a fall in blood pressure, a friction rub and even electrocardiographic changes so closely simulated coronary artery thrombosis that the true diagnosis became apparent only after the discovery of the urinary abnormalities and the high blood urea nitrogen.

Dyspnea was by far the most prominent cardiac symptom occurring in thirty two cases. As a rule patients first began to complain of this on exertion about one year—occasionally longer—before death. As the disease progressed with an increase in the diastolic pressure and gradually developing cardiac and renal failure shortness of breath became more severe. Shortly before death it was present in practically every patient.

In the late stages the dyspnea was not always exclusively cardiac. Frequently cardiac failure was complicated by severe anemia, acidosis and a failing cerebral circulation making it very difficult at times to evaluate satisfactorily the various components that brought about the difficult breathing. Typical Kussmaul breathing was occasionally observed but Cheyne-Stokes dyspnea was much more frequent. Still another form of difficult breathing recurring paroxysmal dyspnea or acute pulmonary edema, was an important feature in six cases. In one of these the old fashioned sweat bath was responsible for a fatal attack. Another patient was of especial interest because his dyspnea was of such striking severity that some unusual pulmonary complication in addition to cardiac failure seemed evident. Autopsy revealed multiple thromboses of the smaller pulmonary arteries and numerous pulmonary infarctions.

SIGNS

While cardiac symptoms are relatively few in glomerular nephritis and important only late in the disease cardiac signs, as one would expect in hypertensive patients are common, and may occur early with the development of the permanently elevated blood pressure. Their significance varies with the individual signs.

*These cases were first seen at the Children's Hospital of Boston. We are indebted to this hospital for the early data.

SIZE OF THE HEART

An accurate determination of the duration and the degree of cardiac hypertrophy is one of the greatest aids in evaluating the cardiac status of the hypertensive patient. The hypertrophied and dilated heart is destined to failure. No accurate method for determining these factors is available and we are compelled to rely on the somewhat uncertain clinical determination of the position and force of the apex impulse and percussion measurements together with roentgen study.

The location of the apex impulse, together with the percussion measurements, was repeatedly recorded in the forty-four cases that were followed for a considerable period before death. By these clinical methods alone the heart seemed to be of normal size in only eight. It was slightly to moderately enlarged in fifteen and moderately to markedly enlarged in twenty-one cases. A rapid increase in size with onset of cardiac failure was noted in an occasional patient. In most instances the greatest degree of cardiac enlargement was found in those cases in which severe hypertension had been present for over a year.

Repeated x-ray studies, consisting of a fluoroscopic examination and a seven-foot film, were available in eighteen patients. By methods of physical examination alone in these cases the heart was moderately to markedly enlarged in twelve, slightly enlarged in two and apparently of normal size in four patients. In this same group by teleroentgenograms twelve of the eighteen cases had definitely enlarged hearts, five of severe grade. Of the six cases with a normal cardiothoracic ratio, roentgenoscopy showed evidence of hypertrophy of the left ventricle in two. The other four with hearts of normal size by Roentgen ray were also normal on physical examination.

In six cases serial teleroentgenograms over one to five years showed progressive cardiac enlargement, a feature not detected with reliable accuracy by physical examination. In three of these a rapid increase in size accompanied cardiac dilatation, the diagnosis being confirmed at the same time by a feeble beat on fluoroscopy. In another the heart was of normal size until an attack of lobar pneumonia. During the following ten months the heart enlarged so rapidly that acute myocarditis was suspected. However the fluoroscope revealed no weakening of the heart beat and necropsy revealed merely a markedly hypertrophied heart.

On roentgenologic examination the aorta was tortuous in over half of the eighteen patients examined. Most of these were in the older age groups. In none was there dilatation above the accepted normal upper limit of 6 cm. in the left oblique view.

HEART SOUNDS

Even when the heart sounds were carefully described in patients followed for several years, the quality, intensity, and splitting of sounds seemed to have but little significance except, perhaps, at the very end. In forty-one out of fifty-six patients the second sound at the aortic area was of increased intensity, accompanied in most instances by an accentuated first sound at the mitral area. This is to be expected with the elevated blood pressure. Diminished intensity of the first sound at the mitral area was only rarely noted.

ARRHYTHMIAS

Prior to the onset of uremic pericarditis clinical irregularities of the heart beat were uncommon. Of the sixty-six cases, premature beats in six and auricular fibrillation in one were the only arrhythmias noted. Those occurring after pericarditis developed will be discussed later.

GALLOP RHYTHM

A gallop rhythm, usually protodiastolic in type, was recorded late in the disease in one third of the sixty-six cases, twelve of these patients had congestive failure. Most of these patients with gallop rhythm died within six months. In this connection, however, it should be remembered that the element of progressive renal insufficiency is of more importance than the cardiac one in the majority of these cases of chronic glomerular nephritis. Therefore the prognostic significance of gallop rhythm can hardly be applied to primary hypertensive patients without renal failure.

MURMURS

In the entire group of sixty-six patients twenty-three showed no murmurs of any kind during the entire period of observation, for some as much as ten years. A fair number of these were, too, severely hypertensive. In forty-three a systolic or diastolic murmur was found at some time during the period the patients were followed. Thirty-seven had a precordial systolic murmur of greatest intensity in the mitral area, these being described as "faint" in seventeen cases, moderately "loud" in twelve, and "loud" in eight cases. A systolic murmur of moderate intensity was sharply localized to the mitral or aortic areas in three cases each. Three more had transient apical systolic murmurs. In ten patients the systolic murmur appeared only with the development of hypertension.

An early blowing diastolic murmur at the aortic area, along the left sternal border, and rarely at the mitral area is not very rare in hypertension. In such cases the heart valves and rings are usually normal at necropsy. A

diastolic murmur of this sort unaccompanied by a thrill, was present in ten cases. In at least three instances it appeared after the onset of hypertension. In two cases the murmur was transient and present only during periods of extreme elevation of the blood pressure. Although anemia was present in the late stages of the nephritis in all of the cases it could not be considered even a possible factor in the production of the diastolic murmurs except in two patients both of whom were adolescents. In one of the six cases in which the diastolic murmur was most typical of aortic insufficiency true structural disease of the aortic valves was suspected. At necropsy, however a markedly dilated pulmonic valve ring was the only valvular abnormality. Of the entire series this case was the only one with appreciable dilatation of a valve ring and in none of the cases did the leaflets show evidence of endocarditis. In four of the ten cases the diastolic murmur occurring early in diastole, was most distinct at the mitral area, resulting in a questionable diagnosis of mitral stenosis in each instance. The presence of diastolic murmurs did not appear to influence the course of the disease in these ten patients, nor was it an apparent factor in the congestive failure which was present in a third of them.

CONGESTIVE HEART FAILURE

Before the terminal stage of chronic glomerular nephritis, congestive failure becomes the most important clinical feature in about one fourth of the cases, as contrasted with primary hypertension where the cardiac factor is the significant one in about two-thirds of the cases. Probably this is due to the greater duration and degree of hypertension in the latter group and to the fact that only about 10 per cent of the patients with primary hypertension die of renal failure. In the primary vascular group the average age of the patients is greater, the incidence of coronary artery disease higher and the degree of cardiac hypertrophy usually greater.

In the present series congestive failure became an important clinical feature and a few months before death in 23 per cent. Left sided failure characterized by paroxysmal dyspnea was the outstanding feature in five patients. As mentioned above, one died in an attack of pulmonary edema produced by the use of the sweat bath. Eight of the ten cases with congestive failure had the usual signs of a failing right heart i.e. orthopnea, severe ankle edema, engorged liver, rales, hydrothorax etc. In the other two cases the principal feature of the right heart failure was recurrent ascites which led to a consideration of cirrhosis of the liver. Abdominal pain due to an engorged liver was so severe in another patient that an acute surgical condition in the abdomen was at first suspected.

In the terminal stage of the nephritis, edema is usually present and is nearly always cardiac in origin and distribution. Late in the disease all but five of the sixty six cases had slight to moderate ankle and sacral edema. Right heart failure with generalized edema in four patients and left failure in one (pulmonary edema) was precipitated by forcing fluids to about 3000 cc in twenty four hours. This is an adequate warning to those who would force fluids in uremia without considering the enfeebled circulatory mechanism in the terminal stages of chronic nephritis. Two cases with a nephrotic component had generalized edema believed to be both cardiac and renal in origin, the rapid development of renal failure having been accompanied by hypertension and symptoms of cardiac decompensation.

PERICARDITIS

One of the most productive parts of our study concerned the pericarditis found in the nephrotic stage*. In the literature the average incidence of acute fibrinous pericarditis in all types of Bright's disease studied clinically and pathologically is approximately 10 per cent. In fifty nine patients with glomerular nephritis who died in uremia a pericardial rub was heard in 36 per cent. Including those cases in which the acute pericarditis was found only at necropsy we find a total incidence in the fifty nine cases of glomerular nephritis of 48 per cent. This unusually high incidence can be explained only by the fact that we were especially looking for the rub or because our series of cases, though large for chronic glomerular nephritis, is after all relatively small. However, the former explanation seems more probable in view of the fact that the frequency of acute pericarditis in a parallel group of fifty five patients who died from vascular nephritis was 24 per cent more than twice that given in the literature for unclassified nephritis. Our total incidence for both groups of cases was 36 per cent.

In our patients the friction rub varied from the extremely soft and evanescent one to the very coarse one which persisted to death. The former is not infrequently missed because one does not happen to listen at the right time. The coarse rub, in our experience, is more lasting, and therefore, rarely missed. In our entire group the rub disappeared permanently in only three patients.

Uremic pericarditis is one of the most important prognostic signs in all medicine the importance of this sign lying in the fact that death occurs ordinarily within a few days to a few weeks after it appears. Barach² however, has reported three patients who have lived from two to twelve months after a rub was heard. In our entire group of fifty nine patients the

* The interest and importance of our observations warrant a separate and detailed report which will be published elsewhere. Only a summary of our findings will be given here.

interval between the appearance of the rub and death varied from one to thirty-six days with an average of seven days

As for signs other than the rub which has been described previously there were but few. Pericardial effusion was commonly present at necropsy but this condition was diagnosed clinically in only one patient on the basis of an increased area of cardiac dullness and diminished intensity of the heart sounds. The pulse and temperature rose moderately in an occasional case, and the blood pressure remained at its previous level except in the rare patient where a fall led to some difficulty in eliminating from consideration coronary thrombosis.

By far the most striking signs were the disturbances of the cardiac mechanism and various electrocardiographic changes.

ELECTROCARDIOGRAPHY

Electrocardiograph studies were available in thirty-eight of our patients. All had hypertension and about half were on a maintenance dose of digitalis. Eight had definite pericarditis. On the whole the electrocardiographic changes occurring prior to the onset of pericarditis seemed to be of minor importance. If we except the eight cases of pericarditis, arrhythmias were noted in but four patients. Three of these showed premature beats and in one there was auricular fibrillation. The thirty nonpericarditic patients may be divided into two groups, those with proved coronary arteriosclerosis and those without such. Of the former there were eleven with moderate to severe coronary artery sclerosis at necropsy. All of these had at least one tracing within two months of death. The electrocardiograms of four were normal, two showed only left axis deviation while in four more there was an additional T wave negativity in all three leads, and a low voltage of the ventricular complex in one case. The electrocardiographic changes of the one patient with coronary thrombosis were those of posterior infarction.

In the remaining nineteen patients without obvious coronary arteriosclerosis at necropsy the electrocardiograms in general differed but little from those in the group of eleven cases with definite coronary artery sclerosis at necropsy. A small proportion, two out of nineteen, showed negative T waves in all three leads. In four, the T waves were inverted only in leads I and II. Five cases with normal tracings developed, over a period of months, left ventricular preponderance or negative T waves, rarely both. In about 10 per cent of the series the so-called high voltage electrocardiogram was obtained.⁹

Wood and White⁴ in a study of the electrocardiogram in uremia and severe chronic nephritis described positive deviations of the RS-T segment, T wave negativity, and abnormalities of

rhythm and conduction and attributed these to the effect of the uremic toxins on the myocardium. Pericarditis was described in at least two of these cases. Levine¹⁰ in 1929 presented a case of uremic pericarditis with positive deviations of the RS-T segment similar to those described by Wood and White. Recently Schwab and Herrmann⁵ offered proof that pericarditis was the probable explanation of these T wave changes.

A study of our tracings seems to support Schwab and Herrmann. It is significant that no changes except the ones usually found in hypertensive patients occurred in our cases until pericarditis or myocardial infarction had developed. Thus, of course, does not absolutely exclude uremia or coronary artery disease as a factor.

Let us see what light our data throw on the possible relationship of uremia to the abnormalities found. Quite arbitrarily we have considered that uremia was present when the blood urea nitrogen was 70 mgm per 100 cc or more. For the purpose of comparing the electrocardiographic changes in various periods of the nephritis we divided the patients into three groups as follows:

- (1) Sixteen cases with two or more tracings before uremia developed.
- (2) Fifteen cases in which one or more tracings were taken during well-marked uremia before the appearance of the pericardial rub.
- (3) Eight cases with a total of fourteen electrocardiograms taken while a pericardial rub was present. All of these cases had hypertension. Digitalis effects need not be considered because the drug had been discontinued in all for some time because of vomiting.

Prior to the onset of pericarditis these cases had showed only such minor electrocardiographic changes as axis deviation, T wave negativity, low voltage of the ventricular complex, and an occasional ectopic beat. With the development of pericarditis all of the eight cases except one displayed abnormal electrocardiograms. A positive deviation of the RS-T segment was present in leads I and II in one patient and in all leads of another. The T waves were upright resembling those described by Wood and White. In both patients normal tracings had been obtained a few days prior to the onset of pericarditis. In one of them there was not merely deviation of the RS-T segment but also transient auricular fibrillation and premature nodal beats. Chest leads were normal suggesting that the coronaries were not a causative factor. The changes in the other five patients consisted of transient auricular fibrillation and auricular flutter in two, ectopic

beats (nodal auricular and ventricular) in three and a transient prolonged P R interval in one patient. Two of these cases also had inverted T waves either in leads I and II or in all three leads. Chest lead studies were normal in the latter case.

Although the blood urea nitrogen was slightly higher in these eight cases than in the uremic patients without pericarditis, in both groups the azotemia was severe, averaging 200 mgm per cent and 185 mgm per cent for the two groups. It seems to us probable therefore especially in view of the experimental and clinical studies of Schwab and Herrmann¹ that it was the acute fibrinous pericarditis and not the toxic effects of uremia alone which accounted for the alterations in the electrocardiogram mentioned above. However, some unknown factor other than pericarditis must probably account for the occurrence of abnormalities in the R-S-T sector in but two cases. Schwab and Herrmann believe that these deviations in the R-S-T segment in pericarditis are due to ischemia of the heart muscle caused by interference with the coronary blood flow from a rapidly accumulating pericardial effusion. It is therefore of more than passing interest that one of our two cases with R-S-T deviations had less than 20 cc of fluid in the pericardium at necropsy twenty hours after the tracing was taken. The other patient had 400 cc of pericardial fluid. Of the remaining six patients, one showed a normal amount of fluid in the pericardium, three had hydropericardium of moderate amount, two had 700 cc each. A single tracing in each of the last two cases was normal except for an arrhythmia in one.

PATHOLOGY

As the most important pathologic features of the discussion we have selected the weight of the heart, sclerosis of the coronary arteries, pericarditis and the histopathology of the myocardium. Complete data regarding the heart were available for study in fifty nine of the sixty six cases. Fifty three of these died of uremia and death in the remaining six was due to other causes before renal failure became complete. All of the fifty nine cases had hypertension. The duration was known to be more than a year in most of the cases and at least five years in a fifth of those dying of uremia.

The cardiac weights of the fifty three patients who died of uremia ranged from 230 to 670 Gm, averaging 447 Gm, while the average weight of the heart in the six patients who died earlier before renal insufficiency became complete was only 375 Gm. We have arbitrarily used 400 Gm. in the female and 450 in the male as the upper limits of normal weight of the heart. On this basis twenty seven (51 per cent) of the fifty three cases of glomerular nephritis with complete renal insufficiency had hearts above

normal weight, while only one patient in the nonuremic group was found to have a heart above normal weight. The increase in heart weight was mainly due to left ventricular hypertrophy. Even in those cases whose hearts were within normal limits of weight, 50 per cent showed definite hypertrophy of the left ventricle.

The walls of one or both coronary arteries were definitely thickened in fourteen of our fifty nine autopsies. Seven of these fourteen died in the fifth decade, two in the fourth, three in the third and one each in the second and seventh. The average weight of these fourteen hearts was slightly less than that given for the entire series. Narrowing of the lumen was present in five cases with an old thrombosis and myocardial infarction in one. The incidence of definite coronary artery sclerosis in this group of glomerular nephritis is practically the same as that given in nonhypertensive heart disease for all ages by Bell and Clawson.¹²

Definite acute fibrinous or serofibrinous pericarditis was present in 48 per cent of the cases dying of uremia. Two cases showed advanced organization of the exudate and almost complete obliteration of the pericardial sac. In the others there were fresh adhesions with varying amounts of pericardial fluid. Hydropericardium of more than 75 cc was present in twelve patients, the largest amount being 700 cc and the average 300 cc. All had ascites or hydrothorax or both. In seven of these congestive heart failure played a part. It is significant however that in only one patient was hydropericardium present without pericarditis. It is also of interest to note that in these patients with pericarditis there was no inflammation of the other serous membranes except an acute pleuritis accounted for by pneumonia.

The pericardial exudate of uremic pericarditis is almost invariably sterile and when microorganisms are found they are usually considered to be secondary invaders. Cultures were sterile in all of our patients but one. In this case two types of bacteria (*B. coli* and a streptococcus) were isolated. These were definitely associated with a superimposed terminal infection of the pericardium. Histologic examination revealed in addition to the mononuclear infiltration of the pericardium commonly present in sterile uremic pericarditis a moderate polymorphonuclear cell infiltration.

The routine histologic study of the myocardium was usually limited to a single block of tissue, unless additional sections were made through areas found abnormal on gross examination. One third of the fifty nine cases showed slight diffuse interstitial fibrosis usually unrelated to significant sclerosis of the coronary arteries. Moderate patchy myocardial fibrosis was present in three cases of severe coronary sclerosis. When acute fibrinous pericarditis was

present an occasional case showed slight degeneration and mononuclear infiltration of the myocardial tissue beneath the layer of pericardial exudate. The histologic changes found in the myocardium were, therefore, comparatively unimportant.

SUMMARY AND CONCLUSIONS

1 Clinical and pathological observations have been made on the heart in sixty-six patients who came to autopsy with chronic glomerular nephritis.

2 The heart in this disease is essentially the same as the heart in primary vascular hypertension except for the modifications brought about by the lower average age, the duration of the hypertensive process, the degree of hypertension, and by the terminal uremic pericarditis.

3 The incidence of acute fibrinous pericarditis in fifty-nine patients who died in uremia was 48 per cent, a much higher figure than previously reported in the literature.

4 Our observations on the electrocardiographic changes occurring in uremia suggest that pericarditis is a more responsible factor than the uremia.

5 The frequency of cardiac disorders in

the last year of life and the significant rôles they at times play, emphasize again the importance of regarding glomerular nephritis not as a specific disease of the kidneys but as a generalized vascular and metabolic disturbance in which the extrarenal factors can never be ignored.

ENORMOUS BENIGN GASTRIC ULCERATION CAUSED BY MULTIPLE FOREIGN BODIES

BY PHILIP H WHEELER, M D *

THE presence of foreign bodies in the stomach has been reported often, but ulceration of the stomach from such foreign bodies seems to be much more unusual. Such reports in the literature are few. Judd and Phillips¹, however, state that they consider ulceration caused by foreign bodies to be fairly common. Among these are two cases of gastric ulceration reported by E A Hallas², of Copenhagen. One of the cases showed the scar of healed ulcer. He also mentioned two cases, one reported by Tidemand, another by Grauer. The foreign bodies in all cases were cement casts of the stomach. In none of them was the ulceration larger than the size of a two mark piece of pfennig (18 mm).

A case of an unusually large benign ulceration caused by multiple sharp foreign bodies in the stomach, which entirely perforated the gastric wall without any resulting peritoneal contamination, is reported in this paper. We have been unable to find any such similar case reported in the literature. It is likely that the extreme sharpness of the foreign bodies was a very active factor in formation of the ulcer

and it is remarkable that none of these found a way into the abdominal cavity.

The patient, B T, a former railroad telegrapher, forty-three years of age, white, male, was a mental patient at the Brattleboro Retreat where he had been committed for the second time with a diagnosis of manic depressive psychosis, depressive phase. For a period of several months he had been vomiting occasionally, with increasing frequency. There was coffee ground vomitus with the occasional appearance of bright red blood. The stools were tarry. Careful observation of the patient by attendants led them to believe he was taking foreign bodies into his stomach. X-ray examination, October 10, 1933, by Dr C S Leach at the Brattleboro Memorial Hospital revealed a large irregular opaque mass in the cardiac region of the stomach about three inches by four inches in size which appeared to be made up of metal including staples, tacks, and wire. Staples and tacks were visualized in the right abdominal area in the colon (Plate 1). Catharsis delivered staples and tacks. On October 19, 1933, x-ray again showed the gastric mass still present. Two small pieces of metal and a short piece of wire apparently in the ileum and rectum, respectively, were present in addition. Dr Horace G Ripley, Superintendent of the Brattleboro Retreat referred the patient for immediate operative treatment as his vomiting and gastric pain were persisting and his general physical condition was becoming more and more poor.

When examined the patient was very anxious for relief and freely told of the foreign bodies he had swallowed during a period of three to four months

*Wheeler Philip H—Assistant Surgeon, Brattleboro Memorial Hospital. For record and address of author see "This Week's Issue" page 849.

Before operation he prepared a partial list of objects he had swallowed in order that they might not be overlooked. Many of the objects such as razor blades, needles, pins and glass he had covered with gum, food et cetera. Yet in spite of these precautions he said that his throat had become very sore at times. His admitted intent was suicide, but death in this manner became so hard that he changed to become a very cooperative patient.

Physical examination revealed a moderately emaciated and pale, neurotic patient in some distress from epigastric pain. The teeth, ears, eyes, nose,

vertebral tenderness. Genitalia were normal. Rectal examination was negative. Reflexes were physiological. B P 120/80 weight 120 pounds pulse 80 temperature 98 respiration 20. The urine showed albumin slightest possible trace, rbc, rare, wbc, frequent. Blood count showed rbc 4,156,000 hemoglobin 65 per cent, wbc, 31,700. Polymorphonuclears 78 small lymphocytes 19 large lymphocytes 2 eosinophils 1.

Gastrotomy was performed October 30, 1933 and revealed a large stomach with the omentum adherent to the lower third of the lesser curvature. The stomach was opened through a transverse incision opposite this point. Numerous intermingled foreign bodies were removed with forceps and fingers. The entire gastric mucosa, especially along the lesser curvature, was badly lacerated, and friable. The omentum adherent to the lesser curvature covered the head of an ulcer 45 mm. by 32 mm. eroded entirely through the gastric wall (Plate 2.)

PLATE 1

and throat were negative. The lungs and heart were negative to examination. The abdomen showed tenderness to pressure in the epigastrium. No organs or masses were palpable. There was no costo-

PLATE 2

PLATE 3

Tissue immediately surrounding this was extremely friable. The original gastric incision was extended to permit resection of the ulcer. Closure was made, leaving a drain to the lesser omental cavity.

The pathological examination was made by Dr Theodore P Eberhard.

"Sections from four places around the edge show the following. Sharp end of mucosa followed by a thin layer of fibrin and necrotic tissue. The base of the ulcer was composed of granulation tissue and chronic inflammatory cells with complete destruction of the muscularis at some places, and partial replacement at others. The process had spread beneath the muscularis mucosae to the limits of the specimen in some places, and was heavily infiltrated with eosinophils. There is marked activity of the endothelium of the granulation tissue and occasional mitotic figures were seen. No evidence, however, of epithelial malignancy. Gastric ulcer."

Classification of the foreign bodies removed showed sixty nine narrow staples, twenty four wide staples, twenty one pieces of glass, one pencil lead, seventy two miscellaneous metallic foreign bodies including open safety pins, hairpins, corroded needles, pins, tacks, pieces of safety razor blades, a piece of hacksaw blade, and a screw (Plate 3). In addition to these foreign bodies two small nails, two staples, and two pieces of glass in the intestines were later delivered by enemata.

A gastric fistula opened through the drain the seventh postoperative day and closed spontaneously on the twentieth postoperative day. It never gave further trouble. The remainder of the wound healed per primam.

The patient continued to gain after discharge to the Biattleboro Retreat on his twenty fifth postoperative day until November 13, when he suffered recurrence of pain typical of gastric ulceration. No knowledge was ever obtained of his taking more foreign bodies. A modified Sippy régime was ineffective. The patient was suffering severely, losing weight and strength. At this time he was despondent and attempted suicide. As a last resort he was placed on a course of Synodal. Coincident with the last treatment he became free of pain and commenced to gain. To the present he has remained in good health and at his normal weight. He occasionally has complained of minor gastric discomfort but there has been no vomiting, definite pain, or tarry stools. His mental recovery kept pace with his physical improvement so that he has been allowed vacations and discharges, from which he has voluntarily returned when the stress of society has become too great. He has shown no inclination to resume his suicidal tendencies and has good mental insight.

ORTHOSTATIC ALBUMINURIA IN HOMOLOGOUS TWINS*

BY HENRY J BAKST, M D,† WINTHROP WETHERBEE, JR, M D † AND JOHN A FOLEY, M D †

THAT albuminuria may exist in the absence of any demonstrable pathology of the genitourinary tract is a fact which has been generally recognized since the appearance of Moxon's paper in 1878.¹ Although attention had been called to this matter previously, general acceptance was wanting until that time. Confirmatory reports then followed in rapid succession, with at least three in the same year^{2, 3, 4} and innumerable others since that time.

The term "orthostatic albuminuria" was first used by Heubner in 1911. Of the many theories available in regard to its mechanism of production, those of Jehle, Erlanger and Hooker, and Senator have received the widest attention. The first named holds that lordosis of a particular type involving the upper spine (12th dorsal and 1st and 2nd lumbar vertebrae) is responsible for the production of albuminuria because of stasis resulting from interference with renal circulation.⁵ Erlanger and Hooker believe that the chief factor in the production of orthostatic albuminuria is a diminished pulse pressure which occurs with the change from the reclining to the erect posture.⁷ Senator, however, pointed out that orthostatic albuminuria is indicative of some degree of

renal pathology, even though it may not be demonstrable by the methods now at our disposal.⁸

Various modifications of these three main ideas exist. It has been suggested that the condition may be due to a congenital histological defect resulting in increased glomerular permeability,⁹ or to local acidosis resulting from renal stasis.¹⁰ It also has been proposed that many cases of orthostatic albuminuria have their origin in infection,¹¹ and Janeway pointed out that a postnephritic albuminuria may often be brought out by standing, and that it may be increased by exercise.¹² In addition, it has been noted that orthostatic albuminuria occurs most commonly in a thin individual with poor muscle tone, visceroptosis, vasomotor instability and low blood pressure. The chief factor here is renal stasis, due to compression of the left renal vein between the aorta and the mesenteric artery. This view is favored by the fact that in lordosis, the aorta is pushed forward, and, in visceroptosis, tension is applied upon the mesenteric artery.¹³

In order to establish the diagnosis of orthostatic albuminuria, certain definite criteria must be satisfied. The essential finding is that of albuminuria when the patient is erect, and its absence when the patient is recumbent. In addition, as Thorp and Wakefield have pointed out, the sediment must be free from casts and erythrocytes, there must be no history sugges-

sign of nephritis or nephrosis, and no physical sign commonly associated with nephritis.¹¹

There have been many reports of various diseases occurring simultaneously in homologous or identical twins, but a careful review of the literature has failed to disclose any report of the occurrence of orthostatic albuminuria in identical twins.

CASE REPORTS

J. C., aged nineteen was referred to the Boston City Hospital on May 13 1935 by his family physician. The patient had applied for training with the Citizens Military Training Corps and had been rejected because of the presence of albumin in his urine. He was then referred to the Hospital for an investigation of this finding. The patient had no complaint of any description and felt well in every respect.

The past history was not remarkable. There was no history of symptoms referable to kidney disease no nocturia frequency hematuria edema, visual disturbances, headaches or similar complaints. He had had a tonsillectomy and mastoidectomy at the age of five. He had also had measles pertussis and chicken pox during his childhood. There was no history of scarlet or rheumatic fever sore throats pneumonia pleurisy or joint pains. He did however give a history of "bilious attacks" occurring at rare intervals consisting of headache nausea and anorexia usually lasting about an hour.

The patient's habits were not remarkable. He usually smoked less than a package of cigarettes drank one cup of coffee and three cups of tea daily and used no alcohol.

On physical examination he was found to be seventy-nine inches in height and 163 lbs in weight. His blood pressure was 120 mm of Hg systolic and 80 mm of Hg diastolic. The examination was entirely negative. The eye grounds were normal. There was no cardiac enlargement, and no murmur was made out. There was no scoliosis-lordosis or kyphosis.

Laboratory studies revealed no abnormal data. The hemoglobin and blood morphology were within normal limits except for the finding of 4 per cent eosinophils in the differential smear. The blood serology was negative, and the chemistry including the nonprotein nitrogen blood urea nitrogen blood chlorides, total protein and albumin-globulin ratio were entirely within normal limits as were also the urea clearance, phenolsulphophthalein excretion, and urinary concentration tests. The daily urines showed wide variations in specific gravity with occasional albumin in varying amounts no sugar and a negative sediment.

X-rays of the kidneys ureters bladder chest, gastrointestinal tract, anteroposterior and lateral views of the spine and pyelograms were negative.

V. C., twin brother of the above entered the hospital on the same date for the same reason. He likewise felt perfectly well had no complaints of any kind and appeared to be in good health.

The past history was essentially not remarkable. He had had a tonsillectomy at the age of five, and also had had measles chickenpox, and pertussis at the same time that his brother had had these illnesses. In addition he had had a mild attack of diphtheria. There was no history of renal disease rheumatic fever tonsillitis pleurisy pneumonia or scarlet fever.

His habits varied slightly from those of his brother. He used a considerable amount of tobacco

including cigars pipe and cigarettes. He was accustomed to drink tea and coffee moderately but did not drink alcohol in any form.

Physical examination failed to reveal any abnormality save for a soft blowing apical systolic murmur which was heard only by one examiner. The heart was not enlarged the rhythm was regular and the pulmonary second sound was not accentuated. The blood pressure was 125 mm of Hg systolic and 80 mm of Hg diastolic. He was 70½ inches in height, and weighed 155 lbs.

This patient was put through the same laboratory procedures as his twin brother and here again, the results were entirely within normal limits. The same x-ray studies were also negative.

The family history revealed several interesting facts. The mother was supposed to have had "kidney trouble" during her second pregnancy (her first pregnancy had resulted in a stillbirth). The pregnancy in question however proved to be an eventful one and she went through several subsequent pregnancies which were normal in every respect. Besides the twins aged nineteen there are four healthy children three boys aged eighteen, seventeen and sixteen and one girl aged thirteen. The father is well except for the fact that he suffers from hay fever. This was of interest in that one of the twins showed probable allergic manifestations.

The maternal grandfather died of tuberculosis and the grandmother of childbirth.

The paternal grandfather is living and well and the grandmother died of cardiovascular renal disease.

One of the boys' aunts had had twins, and a first cousin also had had twins each on one occasion.

The twins were delivered at the Homeopathic Hospital in Boston on August 22 1915. One weighed 5½ pounds at birth, and the other weighed 6 pounds. This difference in weight persisted through childhood. They were always very similar in appearance in fact, they were indistinguishable to people outside the family circle. Their features and bodily characteristics showed a most striking similarity and while they were on the ward the nurses and doctors had difficulty in distinguishing them. Their mental reactions were likewise very similar and their school work had always been of the same quality. Both were right-handed and were moderately athletic. One (V) wore glasses for reading the other did not.

The criteria for the recognition of identical twins mentioned by Leavitt¹² were fulfilled in that the boys showed a striking similarity in appearance in mental physical and emotional characteristics had similar birth weights and birth and life histories. It was not possible to determine whether there had been a single placentation.¹³ The general summation of resemblances¹⁴ was so striking as to leave no doubt in our minds as to their probable enzymotic origin.

In attempting to form an evaluation of the renal function in each case it was felt that in view of a negative history and physical examination, normal blood chemistry and renal function tests, and negative urines save for the presence of transient albuminuria, we were entirely justified in assuming that demonstrable renal pathology did not exist. This point of view was further supported by negative x-rays of

the kidneys, ureters, and bladder, gastrointestinal tract, and dorsolumbar spine and negative pyelograms. It was further felt that we had not only excluded the presence of organic renal disease, in so far as was possible, but had also ruled out such factors as abnormal kidney position, aberrant ureteral course, and postural scoliosis.

In addition, the diagnostic test advised by Janeway was complied with in each instance.¹ The routine morning specimens from each patient showed the presence of albumin (they had been up and about the ward before passing the specimens). They were then put to bed and specimens were collected at the end of the first and second hours. These proved to be free of albumin. After standing for an hour in a lordosed position, the patients again voided. At this time J's specimen showed a slight trace of albumin, and V's a trace. After an hour in bed J voided a specimen which proved to be free of albumin, while V's showed the presence of the slightest possible trace of albumin. An hour later both specimens were albumin free.

SUMMARY

We have attempted to present briefly an instance of the occurrence of orthostatic al-

buminuria in identical twins, together with some of the views in regard to its etiology, and the accepted criteria for its diagnosis.

ANOREXIA IN CHILDREN

BY MERRITT B LOW, M D *

THE incidence of anorexia in preschool and school children has been variously estimated to comprise twenty to eighty-five per cent of the pediatrician's practice. Brennemann states that "It is a matter of common knowledge among pediatricians that somewhere around fifty per cent of children seen in private practice do not eat well." In a scientific investigation made among educated people in a university neighborhood the incidence of anorexia was stated to be eighty-seven per cent. A pediatric colleague with a large office practice in a prosperous suburb estimated it at eighty-five per cent in his practice. A very prominent pediatrician has said that "he paid for his house with anorexia." Capper says, "The complaint of loss of appetite, or unwillingness to eat, not only constitutes the basis of the chief complaint in about thirty per cent of a pediatrician's office practice, but it also forms a chief secondary complaint in other so-called chronic diseases."

A practical working knowledge of what constitutes a suitable diet for children is the common property of all those scientifically or professionally interested in the subject. The aver-

age mother of today knows more about the essentials of an adequate diet as expressed in terms of food elements, foodstuffs, vitamins, iodine content, calories, etc., than did the best informed physician of twenty-five years ago. Yet the nutritional results are far from satisfactory. So stereotyped is the monotonous similarity of feeding histories in children that just won't eat that the pediatrician can reconstruct each one ahead of time. The children are not "sick"; they have no demonstrable organic illness, and the problem is not merely one of nutrition.

The chief cause of anorexia in children is well known by physicians to be psychic. It undoubtedly comes from the struggle of trying to standardize a product which is fundamentally individual. The evolution of so-called scientific artificial feeding has been a long, devious, and complicated process. During the past fifteen or twenty years, "standard" charts have crept in to our appraisement of the individual. A normal gain in weight is certainly one of the essential attributes of growth in childhood and is the best single, comparative, objective measure of normal physical development that can be expressed in figures. As a natural corollary have come height and weight charts, and the scale and measuring rod have become ar-

*Low Merritt B—Surgical Resident, Children's Hospital Boston. For record and address of author see *This Week's Issue* page 849.

biters of nutrition. The accumulation of a vast amount of new knowledge concerning an adequate diet has placed the emphasis on the physical to the exclusion of the psychological aspects of nutrition. Stature, weight and size have come to be intimately connected with, and sometimes synonymous with, health, resistance to disease, and many other less tangible but none the less valuable characteristics. The natural effect on modern mothers when confronted by standards has been to proceed to standardize their children to make them weigh what they should according to height weight tables. That the etiology of anorexia is often purely psychological becomes evident when it is found that it is cured by hospitalization, summer camps, boarding school, etc.

Attempting to make children's weight conform to the standards of charts is the principal cause of anorexia. Schultz says "The environment of the child particularly its relationship to the mother or the immediate attendant, is probably the largest contributing factor or additive cause in the development of anorexia and creates often the most difficult problem in the successful and permanent relief of the condition." To the harassed mother of a "problem" child, with its somewhat intangible, difficultly treated "bad habits", we have in the eating of food a most tangible battlefield for the attempt to "reform", and a place to focus attention with an easily evaluated result. Furthermore the mother easily rationalizes her self into thinking that here is no mere bad habit but a matter of life and death. Probably the most prominent cause of loss of appetite in an otherwise well child is the attempt to make the child eat a definite amount of food at each meal, day in and day out. As Holt has said however "Not what one eats but what one digests, matters."

Summing up then there are at least three factors which enter into the explanation of this biological phenomenon, the young refusing to eat. First it is a common trait of human nature to rebel against arbitrary authority. Cameron and others call this 'negativism'. When a child finds himself confronted by an arbitrarily imposed inflexible system of foods and feeding, he exercises a normal rebellion against a system which allows no choice whatever on his part as to time, place, kind, amount or manner of taking food, and which does not consider whether he is hungry or indisposed at the time. Secondly, it is again a part of human nature to glory in attention. A complacent triumph often characterizes the faces of children as their mothers recite to the doctor the long, woeful tale of their refusal to eat. Having been taught by circumstances how to acquire the spotlight, the child uses the tools at his command. Thirdly it is well known and an established fact that physical

discomfort (hunger contractions) is abolished in the presence of emotions. Pavlov, Cannon and others have conclusively demonstrated and explained the dependence of digestion on the mental state. Thus, forced feeding may have a direct harmful effect on the stomach that is not ready to function, and varying degrees of gastric atonia may ensue. Final support for the tenability of the psychic hypothesis of anorexia is furnished by the interesting experiments of Davis, who has shown that infants six to eight months of age and up when placed before a varied assortment of simple foods will invariably select a well balanced diet for themselves, adequate in every respect and such babies never become anorexic unless sick. Of course there are other factors in anorexia than the psychic ones mentioned above: fatigue, excessive quantities of a particular food (e.g., milk the baby sucking on the bottle simply because it is pleasurable), the stresses and strains of modern "in-door" life. In the main however, the above mentioned are the factors involved in the production of what Brennemann has called an "active immunity" against eating and in fact, all discipline.

Now, then, are we to cope with the situation? The theory is obvious. First, we must make sure that an adequate diet (as regards quantity and quality) is provided and, secondly, no child must ever be forced to eat (with rare exceptions, as in typhoid fever, etc.). The elimination of organic disease (focal infection, anemia, chronic pyelitis, tuberculosis, syphilis, nasal obstruction, carious teeth, etc.) must be insured. It is probably wise to take the history in the absence of the child. 'Tonics' of various types undoubtedly have their place if only for the psychological effect. Oftentimes, when there is a "medicine", the mother will pay less attention to the eating, at least from the active standpoint. The intimate relation between mother and child from the start as regards nutrition is a fertile breeding place for all the tribulations that arise from anxiety, and any relief from anxiety and focussing attention often works wonders. The importance of the anxiety factor in the parents cannot be overstressed as regards all child behavior problems: feeding, enuresis and many others. A preliminary period of starvation is recommended by some. Small doses of insulin have been tried, but this is not often a happy choice. The "feeding habit" the well defined periodic desire or need for food occurring several times a day which is found in all healthy animals, must be cultivated. Attention must be given to taste and appearance of food, and eating between meals must be forbidden. The regulation of all bodily habits must be attained. A just system of reward that bears no connection with bribery seems warranted at least in many instances. It is im-

portant to remember that caloric requirements (i.e., calories per pound of body weight) decrease with the age of the child. A word of caution must be inserted here in regard to the so-called "bitters." Cushing and Carlson say, "We conclude that in therapeutic quantities the bitters, acting in the stomach alone, have no effect on gastric tonicity, on the gastric hunger contractions, or on the parallel sensation of hunger. In greater than therapeutic doses the bitters inhibit the hunger contractions and abolish the hunger sensations in direct proportion to the intensity and duration of the stimulation of hunger contractions and hunger sensations." The conclusion is thus that the beneficial effects from the use of bitters are largely or entirely psychic (as indeed, is much medicine), and the prescriber is much more important than the prescription.

One cannot fruitlessly nag or force a child to eat without losing that wholesome spontaneous discipline that alone leads to a normal behavior reaction. It is important to make few requests and have them obeyed, rather than many which are not "followed through." Cameron suggests that the best way to combat the child's "negativism" is often to appear to the child as determined to prevent him from eating too much, and not as eager to see him eat well. The mother's duties in regard to her child are therefore (as summed up by Sweet) (1) that she provide the child with regular meals, (2) that the meals be of good quality, (3) that the child shall come to the table with clean hands, so he may handle his own food, table manners should not receive too much attention, because eventually the child will copy the manners he sees, not the ones he hears about, (4) that he shall remain at table a definite length of time, for example, thirty minutes, (5) food must be served without one word being said about food. Food is of and from the parent, feeding is solely within the province of the child. We must let hunger lead to appetite and appetite urge on to the acquisition of food. There is no greater joy in life than to have urgent, earnest desire satisfied as the results of one's own efforts. Self-satisfaction is one of the true rewards of all endeavor. We must therefore allow our children the privileges of hunger and the joy of appeasing it.

In conclusion, as elsewhere prophylaxis seems to be the most practical key to the problem, as far as future progress is concerned. We are, furthermore, privileged to work in this disease with the brightest type of child, the sensitive high-strung slightly neurotic child who is to be the standard bearer and pioneer as an adult. New health standards in addition to height, weight, and gross size must be drawn up and borne in mind. Examples of these

might be posture, nervous stability, reactions to environment, resistance to disease, blood picture, intelligence, etc., difficult but very important standards to set. The importance of detail in the upbringing of babies cannot be over-stressed. Six to eighteen months is the crucial age. Feeding from the spoon should probably be started at one or two months. Just because the infant likes to suck, he should not be given excessive amounts of milk from the bottle between six and twelve months of age. No bottle should be indulged in after a year. The child should begin to feed himself at fifteen to eighteen months. Above all, we must bear in mind that the child has an individuality of his own which is entirely different from the individuality of adults. There is something biologically primitive about him that cannot be rapidly transformed into the more stereotyped requirements of adult life, and particularly of a confused "civilization" that is now moving so swiftly that even the adult is often lost trying to keep going. In growth and mental and physical expansion, there is a delicate balance between direction and self-expression, between convention and originality, between regulation and the fostering of initiative, between having one's problems solved and solving them, between prohibition and freedom, between the acceptance of the old and the desire for the new.

VERMONT STATE MEDICAL SOCIETY

CHEMISTRY IN RELATION TO THE PRACTICE OF MEDICINE*

BY C. F. WHITNEY, M.D.

A GENERATION ago the necessity of the study of chemistry as a preliminary to the practice of medicine was doubted by many and even now medical students ask what is the relation of biochemistry to medicine. Prior to the last century, due to the dearth of known facts, chemical thought was largely limited to speculation. Having its origin, like the practice of medicine, in magic, explanations were largely fantastic rather than rational. Chemistry has made great strides during the last fifty years and one can assert without fear of contradiction that the elimination of superstition in use, less remedies and foolish practices and the substitution of a rational treatment may be credited largely to the close and detailed study of the exact sciences, such as chemistry and physics.

A recent addition to the chemical armamentarium is the branch known as physical chemistry. Due to the fact that most reactions in the body are those involving surface phenomena and ionic dissociation in an organism made up largely of colloidal particles, one realizes the importance of a knowledge of surface tension, colloidal dispersion, interfaces, salt equilibrium, aggregation and dispersion, diffusion, viscosity, oxidation and reduction, x-radiation, radioactivity, high tension and high frequency phenomena, electrical potential, optics, etc.

Physiology, pathology, and immunology could never have even distantly approached their present value were it not for the stimulus of chemical ideas and facts, nor could the field of nutrition have advanced to its present position without the help of chemistry. Formerly one spoke in vague terms of stimuli passing from nerve to nerve through nerve fibers like the wires of a telegraph system. We now know that this impulse is transmitted from nerve fiber to nerve cell by liberation of a minute charge of acetyl choline.

The weight of this substance used to transmit a single nerve impulse to a single ganglion cell is so minute as to be about equal to 10 to the minus 21st power in grams, or 20 ciphers to the right of the decimal point followed by the figure one. Therefore, in precise chemical terms we seem soon to be able to describe the transmission of effects from nerve fibres to reception cells in the whole peripheral nervous system. The central nervous system has not been explored

in the same way and remains a deep complex problem.

In the work on vitamins, sometimes called exogenous hormones and on hormones rapid strides are being made. Vitamins C and D have been artificially prepared in the pure state, the chemical nature of A is known and the pure crystalline vitamin B is available commercially.

The hormones are produced in definite parts of the body and carried by the blood and lymph to other parts where changes are effected. The estrus producing hormone which is excreted in the urine in pregnancy can be extracted from the urine in large quantities by benzene and crystallized. This substance is now known to be one of a group of condensed ring compounds consisting of a phenanthrene molecule fused to a 5 membered ring and common to the organic compounds occurring in the body. Methods for separating the different principles of the pituitary lobe, appropriately called the conductor of the endocrine orchestra, which presides over the sex gland activities, normal growth, and in some ways seems to antagonize the overaction of insulin are already being used. The chemical structures of epinephrine and thyroxine are now known and they are being prepared by artificial synthesis. Likewise the chemical structure of one of the female sex hormones is known and synthetic production will undoubtedly be made soon. Insulin is also obtained at the present time in crystalline form, though its chemical structure is not known.

The body is essentially organic in nature with 70 to 80 per cent water. It consists of proteins, fats (lipins), carbohydrates and mineral substances. All parts except the bones are of a fluid to plastic solid consistency, each maintaining its physical condition essential for proper functioning by chemical combination of very intricate and as yet little known nature. The mineral substances such as sodium, potassium, calcium, phosphorus, iron, iodine and sulphur are perhaps the simplest when considered by themselves, but in the body they are in organic combination and each absolutely essential for normal physiological action. Sodium and potassium, though very similar chemically, cannot replace each other, both being essential. Calcium and phosphorus in definite ratio and with the aid of vitamin D are essential for proper bone growth. The former is also necessary for blood clotting and the latter for the metabolism of carbohydrates, fats, mus-

*Read at the Annual Meeting of the Vermont State Medical Society at Rutland, October 17, 1932.

†Whitney, C. F.—Professor of Physiological Chemistry and Toxicology, University of Vermont. For record and address of author see "This Week's Issue," page 849.

cle contraction, etc Iron is necessary in hemoglobin and acts as a catalyst for internal oxidations Iodine is found in the thyroid gland and sulphur is necessary for growth and development This is a brief review of the value of the most important inorganic constituents A few others, including copper, are necessary, but less is known of their value

The carbohydrates used in foods are mostly confined to starches and the common sugars, which after digestion are absorbed into the blood as single sugars and stored as glycogen, circulate in the form of glucose, or are converted into fat The chief fatty foods are the well-known common fats These are absorbed and circulate in the blood as simple or compound lipins and later they are used to produce energy Proteins are much more complex and form huge molecules The molecular weight of hemoglobin which is one of the smallest is about 70,000 as compared with glucose which is 180 Proteins are made up of amino-acids of which there are some twenty-two or twenty-three All proteins are broken down into these comparatively simple bodies (the largest having a molecular weight of 190), before absorption into the blood It is these substances rather than their combination in the form of protein which interest the physiologist and upon which the well-being of the individual depends Fortunately the body can manufacture most of the amino-acids but about a half dozen cannot be so formed, and for that reason must be taken as such in the protein complex

The forms in which substances are excreted are well known but the great and undiscovered chemical changes are those which occur between absorption and elimination This is a most attractive and fertile field which will gradually unfold chemical changes of inestimable value to the physician As an illustration of the chemical changes known to take place in the body one might mention those that occur in the red blood cells in the process of internal respiration When oxygen enters the capillaries of the lungs as the result of increased oxygen pressure, it combines with hemoglobin thereby producing a stronger acid This robs the carbonate salt of its base converting it into carbonic acid and allows the passage of carbonic acid gas into the alveoli As the blood reaches the tissues the pressure of gases is the reverse of that in the lungs Oxygen leaves the hemoglobin to enter the tissues, and carbonic acid gas enters the blood Neither oxygen nor carbonic acid gas can be carried in any appreciable amounts in simple solution, but must be combined in the form of salts The reduced hemoglobin being a weaker acid than oxyhemoglobin, will give up the base taken over in the lung capillaries by the oxyhemoglobin and this base will be

available for union with the carbonic acid gas This exchange of gases is greatly aided by the passage of chlorine, and to a much less extent the acid radicals of phosphoric and sulphuric compounds, into and out of the red cell Only negative ions are allowed to pass, positive ones being barred This knowledge explains one of the chief mechanisms which regulate the acid-base balance of the body, changes which if equal to the difference between the hydrogen ion concentration of tap and distilled water would be incompatible with life

The arbitrary ways in which physicians in the past have outlined diets for their patients have often been unfortunate, allowing this and excluding that, red meat and white meat, no fruit juices with milk, no protein in nephritis or high blood pressure, etc Even now there are those who do not realize that most fruit juices owe their acidity to organic acid salts which leave an alkaline residue after metabolism, and so tend to reduce acidity rather than increase it Many things of surgical and medical value were learned during the World War Among them was the cause of "war edema" prevalent in prison camps, the underlying cause being protein deficiency The edema associated with nephrosis is due to a lowering of the osmotic pressure of the plasma Of the two proteins, albumin and globulin, it is the former that is excreted in greater amounts, has a greater osmotic pressure, and is less easily regenerated Blood analysis to determine the amount of these proteins in cases of edema may therefore aid in determining the cause and treatment

Psychochemistry is the name applied to that branch which particularly applies to the central nervous system In paranoia, dementia praecox, epilepsy and manic-depressive psychoses, chemistry is contending with histology in conveying the more knowledge regarding the fundamental changes Chemical examination indicates a deficiency in catalytic iron and neutral sulphur in some of the mental disorders These may be inherent deficiencies which cannot be corrected, but knowledge of these changes may aid in finding the remedy Dementia praecox may yet be found to be a deficiency disease as much as rickets or scurvy, and as amenable to treatment, the required adjuvant being in this case oxygen This deficiency may be due to dietary deficiency, production of toxins or some abnormal nervous interference with proper oxidation In this last connection one is led to believe that the beneficial effects of amytal may be the removal of some inhibitory action upon normal oxidation processes

We hear lately of the rôle of the water balance in epilepsy and of alterations in electrical potential and colloidal dispersion in the manic-depressive psychoses So long as these different physicochemical phenomena function nor-

mally between narrow limits there is no disturbance, but let an unbalance occur sufficient to disturb the equilibrium in oxidation reduction, aggregation and dispersion, hydration and dehydration, electrical potential or sodium potassium and calcium magnesium ratios and a disordered functioning of the brain will result. It has long been known that the metabolism of the brain is very active, no tissue needs more oxygen and no cells will be so quickly destroyed by lack of oxygen. The psychic phenomena shown in partial deprivation of oxygen as in carbon monoxide poisoning and partial suffocation or to increase atmospheric pressure as in caissons, are well known. Cytochrome and gluta thione, besides being essential catalysts for oxidation with iron and other metallic substances, are comparatively abundant in the brain.

Many mental conditions seem to be affected by water balance. Particularly is this true in epilepsy. Free water in tissue spaces holds sodium, and in the cells potassium. Water is also bound in the cytoplasm and nucleus. Fevers can be produced by dehydration, and the delirium of fevers is attributed to increase in bound and decrease in free water. The convulsions and coma of water intoxications are due to increase of interstitial water and through osmosis can be relieved at once by intravenous administration of concentrated saline. It is well known that the size of colloids changes with absorption of water which latter is influenced by contact with acid. It is thought that the explanation of epilepsy rests in the hypothalamus which somehow has some control over water metabolism and the tone of blood vessels.

Much research work has been done on the biochemistry of cancer. Studies have been made of the chemical constitution of tumor tissues, blood analysis in tumor cases, and the metabolism of these growths. Of these three the most hopeful results come from the metabolism studies. Cancer tissues seem to have a high sodium and potassium and a low calcium content. It is more hydropic than normal tissue and the nitrogenous constituents differ from that of normal. Much speculation has resulted from the chemical findings, such as causation based on salt unbalance with its effect on cell permeability and treatment by administration of calcium salts. On the whole, however, little positive help has been gained from chemical analysis of cancer tissue. Blood analysis indicates that the alkalinity of cancer patients is higher than normal but this also is true of a number of maladies, so that little of practical importance has been found in such analyses. In metabolism experiments, it has been found that tumor tissue utilizes an excessive amount of carbohydrate and produces an excessive amount of lactic acid. Tumor tissue is able to utilize very little oxygen in comparison with

normal tissue. For this reason it has to obtain sufficient energy for growth by breaking down an excessive amount of glycogen to lactic acid. This is very different from muscle for example, which is able to form lactic acid from the hexosephosphates. These differences between the metabolism of cancer and normal cells seem to be fundamental and of great importance in the study of the cause of cancer.

In this brief discussion certain phases of the subject familiar to all physicians particularly those having intimate access to clinical hospital laboratories, have been omitted. These would include such subjects as gastric urine and blood chemistry, liver and kidney function and metabolism tests. Nor has any special mention been made of the discovery of insulin and only a brief mention of the vitamins and hormones. It might be mentioned that the determination of blood cholesterol is of assistance in confirming a diagnosis of nephrosis or myxedema or to determine the severity of diabetes, the icterus index test in cases of anemia or jaundice, the blood uric acid estimation in cases of suspected gout, the blood calcium in spontaneous fractures, bone softening, generalized osteitis due to hyperparathyroidism and in tetany of unknown origin, the inorganic phosphorus of the blood in cases of rickets or infantile tetany, and blood creatinine when the blood urea is over 30.

DISCUSSION

PRESIDENT MARSHALL. In regard to this excellent paper a good deal of thought was given as to whom we should have discuss it, and after considerable deliberation it was decided to ask Dr. Paul K. French of Burlington.

DR. FRENCH. Dr. Whitney's paper has opened up for me an unthought of field of speculation. He has stated that:

(1) "So long as the different physico-chemical phenomena function normally between narrow limits there is no disturbance of the brain, but let an unbalance occur sufficient to disturb the equilibrium in oxidation reduction aggregation and dispersion hydration and dehydration electrical potential or sodium potassium and calcium magnesium ratios and a disordered function of the brain will result."

(2) "That no tissue needs more oxygen and no cells will be so quickly destroyed by lack of oxygen."

(3) "It is thought that the explanation of epilepsy rests in the hypothalamus which somehow has some control over water metabolism and the tone of the blood vessels."

He has spoken of the fever produced by dehydration and suggested that delirium convulsions and coma may be due to an increase in bound and a decrease in free water mentioning the immediate relief of the convulsions of water intoxications by the intravenous administration of concentrated saline.

As we think over these statements and their application to the mental and physical brain disturbances,

which we as physicians are continually seeing, may not an understanding of the chemical relationship and balances present in the brain point the way to relieving symptoms by seeking a means of restoring the circulation and metabolism of the tissue to normal? A better understanding of the cause should afford a more successful approach toward relief.

I feel that this paper is going to help me to study, from a chemical viewpoint, the symptoms of my patients, and I believe it can be of real help.

All I could do in the length of time afforded was merely to touch on these things, and I hope this paper will make us think of their relationship so that we will study it out for ourselves.

PRESIDENT MARSHALL Dr Daltou

DR DARTON When you ask me about this subject you have something I don't know a thing about. I studied my chemistry a long time ago and there was not anything applicable to what Dr Whitney has said, and I am entirely unable to discuss this paper.

PRESIDENT MARSHALL This paper is quite technical for most of us. Dr Whitney, have you something to say in closing?

DR. WHITNEY* When I studied medicine I had chemistry, and as I recall I think the only technical procedures that we did were gastro-analyses and urinalyses. At the present time they pay no attention, practically, to either of these, but to the fundamental chemistry so that the student will learn to interpret phenomena and, through chemical means, realize the great importance of chemistry. This physical chemistry is very important, and the knowledge is much more important than it was thirty years ago when I studied medicine. We are often criticized because we do not teach students, in the first year, how to analyze urine, but we do metabolism tests and try to get at the basis and fundamental rather than simple tests.

*Dr Whitney's closing discussion has not been edited by him.

MISCELLANY

POSTGRADUATE FELLOWSHIPS AVAILABLE TO MEMBERS OF THE VERMONT MEDICAL SOCIETY

Under the Division of Public Health of the Commonwealth Fund, the office of which is at 41 East 57th Street, New York City, opportunities are offered to the members of the Vermont State Medical Society to receive postgraduate instruction at the Harvard Medical School, available to at least eight members.

The following statement is from the Commou

wealth Fund indicating the nature of the course and the necessary qualifications.

WM G RICKER, M.D., *Secretary*

Commonwealth Fund fellowships available, in the subjects indicated below, to members of the Vermont State Medical Society given at the Harvard Medical School, Courses for Graduates, 25 Shattuck Street, Boston, Mass.

Medicine, given at the Massachusetts General Hospital, Peter Bent Brigham Hospital or Boston City Hospital. A group of at least six must take the course at one time. Such a group may be made up from any one of the four states in which the fellowships are offered, namely, Vermont, New Hampshire, Maine or Massachusetts.

Pediatrics, course is given at the Children's Hospital. Not more than two may take the course at one time. Fellows live at the hospital.

Obstetrics, courses given at the Boston Lying-in Hospital. Not more than two may take the course at one time. Fellows live at the hospital.

Office Surgery, course is given at the Boston City Hospital, designed for physicians engaged in general practice, subjects studied are surgical problems met in the office, in instruction in the outpatient department. A group of at least six must take the course at one time.

Fellowships are for one month. Preference will be given those who take the course in medicine, for a second month in medicine or in obstetrics, pediatrics or office surgery, when fellowships are available during succeeding years. The stipend is \$250.00 plus tuition and traveling expenses from place of residence to Boston and return.

Qualifications. Applicant must be a graduate of a grade "A" medical school, a member of the Vermont State Medical Society in good standing, must have been in practice at least five years and should preferably be under forty five years of age, and must be a resident of a community of less than 10,000 population. Application blanks may be obtained from the Commonwealth Fund, 41 East 57th Street, New York City, or from the Secretary of the State Medical Society.

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL-PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., Editor

CASE 22171

PRESENTATION OF CASE

A sixty-eight year old white Russian watchmaker was admitted complaining of constipation and bleeding from the rectum.

Six months before coming to the hospital the patient first noted that his bowel movements which had previously occurred regularly once daily, became lessened in amount and frequency. The stools gradually became narrow and finger like in character. For about two months he passed small amounts of dark red blood by rectum, and at the time of admission each bowel movement contained one to two tablespoonfuls of blood. During the three months preceding his entry he developed increased frequency of micturition associated with some burning dysuria. During the past one and a half years he suffered cramp-like pains in his right leg whenever he walked rapidly. For fifteen years he had recurrently a sensation of substernal oppression following exertion or excitement. This had recently become much less frequent.

Physical examination showed a fairly well developed and nourished sallow man in no discomfort. The lips were somewhat cyanotic. The chest was said to be emphysematous in configuration, and expansion was limited. The breath sounds exhibited a prolonged expiratory phase. Occasional expiratory wheezes and musical rales were audible. The heart was not enlarged to percussion. The sounds were loud, regular and a prolonged systolic murmur was audible from the apical to the aortic area. This was transmitted into the neck vessels. No thrill was palpated. The pulse was said to exhibit a slow rising long plateau and slow fall. The blood pressure was 190/85.

The temperature was 98°, the pulse 75. The respirations were 22.

Examination of the urine was negative. The blood showed a red cell count of 4,890,000 with a hemoglobin of 80 per cent. The white cell count was 3,700, 68 per cent polymorphonuclear. A stool examination showed a two plus reaction to the guaiac test. The nonprotein nitrogen of the blood was 38 milligrams per cent.

On the fourth day a first stage combined abdominoperineal operation for carcinoma of the rectum was done. The patient reacted well postoperatively but on the second day he began to complain of a sensation of pressure over the entire anterior chest. At this time the nurse noted that his pulse was irregular and had increased to a rate of 100 to 140. On the morning of the following day there was sudden increase in pain over the sternum and the anterior right chest, and the patient appeared cold and clammy. The lips and hands were markedly cyanotic, and the respirations were labored. The pulse was 140 and grossly irregular at the apex. The blood pressure was 110 to 130/75. The pain became more intense and radiated down the left arm. Examination showed that the right chest was full of coarse rales. An electrocardiogram exhibited auricular fibrillation with a rate of 170. There was inversion of T waves which was said not to be diagnostic of recent coronary occlusion. He had received about six grains of digitalis during the thirty six hours preceding his initial discomfort. On the following day the lungs were clear and there was a squeaky murmur at the apex of the heart. No details were noted. The temperature which had risen to 101.6° on the day succeeding his operation fluctuated thereafter between 98° and 102° for about a week. Two days after the acute attack the pulse was recorded as being regular, slow, and of good volume.

Two weeks after the initial operation a posterior excision of the rectum was done. On the following day his temperature, which had been moderate for the preceding week, rose to 101°. Thereafter for the remainder of his hospital stay it fluctuated between 98° and 100°. Two days postoperatively having received 300 cubic centimeters of an intravenous infusion, the patient suffered a sudden attack of substernal pain. The quality of the pulse remained good and its rate was unchanged. Thereafter there were several minor attacks of precordial distress, but on the twenty sixth day after the second operation he again suddenly developed severe substernal pain. Morphine was administered with some relief. He was found at this time to have a rather marked degree of pyuria and constant vesical drainage was instituted. He became progressively weaker, however and died nine days after his last acute attack, on the fifty third hospital day.

DIFFERENTIAL DIAGNOSIS

DR. PAUL D. WHITE. I think it is of some added interest to know whether this patient was a Hebrew. We do not know the incidence of this disease in the various groups that make up Russia but we do know that cardiovascular disease is very common in Hebrews who have come to this country from Russia.

Apparently his chief complaint was this difficulty with the bowels, giving evidence of a spastic state, bleeding, and local bladder irritation, which, as it turns out later, were the result of a rectal carcinoma.

"During the past one and a half years he suffered cramp-like pains in his right leg whenever he walked rapidly." This of course suggests intermittent claudication, which commonly occurs in both legs but may be limited to one leg.

"For fifteen years he had recurrently a sensation of substernal oppression following exertion or excitement." This sounds like angina pectoris of long duration, fifteen years. Its decrease may have been the result of the inability to walk because of the intermittent claudication. That is all there is in the past history. I would like to know many other things, particularly the physical examination in the past in view of what is to follow. It is quite likely that he had consulted a physician for the intermittent cramp-like pains in the leg and chest and it would be helpful to know what had been found on cardiac examination. We are prone too often to neglect such clues, which may be important and the chief aids to correct diagnoses.

We have then this abnormality of the lungs which may be on the basis either of chronic bronchitis with emphysema and asthma or of left heart weakness. The cyanosis of the lips may be associated with that condition of the lungs or it may be local. Sometimes lips and fingers are blue due to peripheral or local stasis and not to cardiac or pulmonary disease.

"The heart was not enlarged to percussion." Of course such a statement is entirely unreliable in this case because of the pulmonary condition which prevents one from outlining proper heart borders. If the apex impulse could not be felt we would like to have x-ray evidence, but there is no report of such. There should have been some statement as to whether or not the apex impulse could be felt.

From this description I should judge that this murmur was a single murmur, not composed of two separate murmurs, one at the apex and one at the aortic area. It probably sounded the same all over the precordium. It was loud and transmitted into the neck. One of the most likely causes of such a murmur is aortic stenosis. A murmur that is loud and well heard both at apex and aortic area is much more likely to be aortic than mitral. A mitral-systolic murmur is not well heard in the aortic area but an aortic systolic murmur is always well heard at the apex, especially if due to aortic stenosis. There has not been enough appreciation about these points of location and transmission of systolic murmurs. It is conceivable, however, that there may have been separate aortic systolic and mitral systolic murmurs that have not been differentiated in this

record. There is no evidence of a diastolic murmur or of a systolic thrill.

The character of the pulse is certainly important and this description, if not misleading, has probably been put in to give us a further important clue. It closely fits the description of a plateau pulse such as is found with aortic stenosis.

"The blood pressure was 190/85." In other words a definite hypertension which is superimposed on whatever else is present in the heart and makes us wonder if the systolic murmur heard over the aortic area may not be due to aortic dilatation after all, but we should remember that the blood pressure may be high in the presence of aortic stenosis. Evidently the aortic second sound was present. It would probably be mentioned as absent if it had not been heard.

The laboratory examination of the urine reveals no important renal or bladder infection at this time. There is no important anemia. The nonprotein nitrogen of the blood was normal.

"On the fourth day a first stage combined abdominoperineal operation for carcinoma of the rectum was done." Evidently it was hoped that the carcinoma of the rectum might be removed and that the risk which was considerable in this case was worth taking. He was evidently in poor health on the basis of the long history of angina pectoris, of the cardiac findings, and of the pulmonary findings. These are three points which made him an unfavorable risk for operation. There is no note of what anesthesia was used, but that is almost always less important than the skill of the anesthetist.

The sensation of pressure over the entire anterior chest would indicate the probability of auricular fibrillation starting at that time. A pulse is rarely irregular at a fast rate unless there is auricular fibrillation.

"The pulse was 140 and grossly irregular at the apex," more or less as it had been before, but now somewhat faster, sustained at 140 rather than 100 to 140. There was a marked drop in pressure.

"There was inversion of T waves which was said not to be diagnostic of recent coronary occlusion." I expect the inference is that there was no great change in the S-T interval, that is the level where the T comes off from the Q R-S, the shape of the T wave was not indicative of coronary occlusion. That is of considerable importance.

"Two days after the acute attack the pulse was recorded as being regular, slow, and of good volume." This is confirmatory, then, of the diagnosis of paroxysmal auricular fibrillation. At the beginning we noted the irregular pulse and sensation of pressure over the anterior chest. What may we say about that? I believe it is impossible on this evidence alone to tell whether the auricular fibrillation was secondary to his

coronary condition or vice versa. A number of times coronary thrombosis has been diagnosed in a patient with prolonged anterior chest pain and paroxysmal tachycardia without coronary thrombosis. Paroxysmal tachycardia or paroxysmal auricular fibrillation with a rate as fast as this can in itself produce angina pectoris, a kind of status anginosus. That is probably the situation here in view of the fact that he had had angina pectoris on effort for the previous fifteen years. He had narrow coronary arteries or at least an insufficient coronary blood supply. The narrowing of the coronaries in itself may not have been sufficient. We may have in addition aortic stenosis which would reduce still further the volume of the coronary circulation. The status anginosus due to paroxysmal auricular fibrillation with much narrowing of the coronary arteries and some aortic stenosis might explain the beginning of this postoperative complication, but we must assume that there is some other complication too such as congestive failure, if we take into account the increased respiratory difficulty the evening of the signs in the chest and the rales in the lungs. It is not likely that congestive failure or the status anginosus alone or combined can do all this, because we have fever that lasted a week.

Pulmonary embolism is a common postoperative complication, especially in a patient who has had cardiovascular disease. Could this not have occurred here, complicating the paroxysmal auricular fibrillation and angina pectoris? It certainly is very suggestive, especially because of the fact that only one lung, the right, was involved. There is no note of any abnormality of the left chest. The right chest was filled with coarse rales. Did he have pulmonary embolism with infarction in the right chest complicating the paroxysmal tachycardia? It seems to have come on the second postoperative day. On the first postoperative day there was simply the rapid irregular heart action with pain on the next day there was a sudden increase of pain over the chest combined with a state of shock, cyanosis, drop in blood pressure and fever. The other two possibilities that could explain such a state of affairs would be complicating infection in the right lung and coronary thrombosis.

The electrocardiographic evidence is against acute coronary occlusion. Also the localization of the rales in the right lung, unless he were lying on his right side all the time, is against coronary thrombosis with secondary congestive failure. We would expect rales at both lung bases with failure sufficient to give rise to cyanosis and dyspnea.

The paroxysmal auricular fibrillation ceased two days after the acute attack began and several days before the temperature dropped back to normal so that toward the end of that week there was no longer any effect from rapid car-

diac action. You will notice that the heart was said to show a squeaky murmur at the apex when the lung cleared. That murmur was undoubtedly the remains of the loud systolic murmur that had been heard when he first came in, in better condition. This state of prostration in which we find these patients is an important reason why aortic stenosis has frequently been missed clinically in a very sick patient.

We may assume that this recurrence of pain came at the time of the intravenous infusion of 300 cubic centimeters. It is possible that angina pectoris was induced by the increased heart work in taking care of that extra amount of fluid, a thing that does happen in patients who are very prone to angina pectoris. There is no note as to what his pulse rate was at that time or of further electrocardiograms.

He was found at this time to have a rather marked degree of pyuria and constant vesical drainage was instituted. Thus we have a still further complication of pyelitis or cystitis making it more difficult for him to weather all these storms.

We would like to know whether his death was sudden. Was this terminal illness due to coronary thrombosis or pulmonary embolism or infection in a patient with a weak heart who had been through these two operations? Too many cards were stacked against him. I do not believe it is possible to tell from the few notes at the end of the record what the terminal event was.

I prophesy that we will find in this man a moderately enlarged heart (in spite of the statement at the beginning that the percussion failed to show any enlargement) secondary to two factors, hypertension and I believe also some aortic stenosis. Coronary artery narrowing will be present, on the basis of atherosclerosis. Coronary thrombosis is a possibility but there is no proof of it. I expect the aortic valve will be calcified. Paroxysmal auricular fibrillation and angina pectoris were functional events of importance. He also had carcinoma of the rectum, cystitis or pyelitis and probably pulmonary infarction. As for the cause of aortic stenosis if present, it is in just such a patient that aortic stenosis may be discovered usually without a clear history of previous attack of rheumatic fever. Sometimes examinations ten to twenty-five years before give evidence of a murmur such as is described here. I have recently seen a man whom I examined first nine years ago, at the age of fifty-three with a very loud murmur heard over the whole heart, maximum at the apex, and slight enlargement of the heart. I made a diagnosis of cardiac enlargement with mitral regurgitation of unknown cause. Last fall he had attacks of pulmonary edema and on examination he then showed an aortic systolic thrill and serious heart failure. It is possible

that our present case did not have aortic stenosis but certainly that diagnosis would explain best the original cardiac findings as noted in the record at the beginning of his stay in the hospital

DR TRACY B MALLORY This case obviously had two aspects, the medical and surgical. We chose to make the medical side the diagnostic problem, but we would like to hear about the surgical side.

DR DANIEL F JONES I do not know what I can say about this surgically except to tell you that I think that anyone undertaking an operation for carcinoma of the rectum in a man with a heart like this is taking his reputation in his hands and at least trying to throw it away, but I have no such feeling about these cases. If it is possible to get rid of carcinoma of the rectum even at considerable risk—this was a very large lesion and he was very uncomfortable with it—I have no hesitation whatever in trying it. We nearly succeeded in this man. The strange thing is that he stood the abdominal part of the operation very well. He had ether during that time but I agree with Dr White that it makes a great deal of difference as to whom you have to give the ether. I am quite alone on this question, except for one man, and that is Gabriel in London, he and I approve of ether in these cases. The patient had spinal anesthesia with the second stage because we are able to give a small dose and give it low.

There is nothing in regard to the diagnosis that I can speak of here. There is not enough history. There is one thing that I disapprove of very much, and that is the statement that the stools gradually became narrower and finger-like. I think that is a pretty uncertain thing to go by. The books all have a much more picturesque way of talking about it, that is, the 'ribbon stool' but I think it is about as poor a symptom to go by as anything can be, because if you know the structure of the sphincter, you know it is oval, and if the bowel movements are soft you will get a ribbon stool or with any soft movement you may get a narrow finger-like stool. Consequently I do not think that of much value.

As to diagnosis, there is only one thing I can say and that is he should have been examined six months before he came to this hospital. If you want to know why, there is a very simple reason. He should have been examined because he has had a change in bowel habit and sensation, and that is all that any general practitioner or medical man needs to know. I do not expect a general practitioner or medical man to make a diagnosis of carcinoma of the rectum every time, but if there is a change in bowel habit or sensation then somebody who can make a diagnosis should be consulted.

This case shows very well that you have to be careful too, in these heart cases. He stood the first operation very well and we let him go for

two weeks in fairly good condition. It was getting along and we had to operate. After the second operation he did not do so well because he had a load put on him which he could not get rid of and consequently went downhill. He had what you would expect, some infection. It was a very large wound, and many of these cases have temporary paralysis of the bladder as they must have drainage of the bladder, therefore, you must expect some infection of the bladder. He had nothing to indicate any pyelitis. As to lung emboli, an interesting fact is that in spite of the great extent of this operation and the fact that many pelvic operations are likely to cause lung emboli these rectal cases very rarely for some reason or other have lung emboli. I do not know why it is.

DR DONALD S KING The day after operation this patient had an elevation of temperature, pulse and respirations. I was asked to see him with the question of a postoperative pulmonary complication. There were râles throughout the right side of the chest but no definite evidence of pneumonic consolidation or collapse. In view of the story, however, I felt that there was probably beginning postoperative atelectasis. I saw him again the following day, and in the meantime the patient had had the acute attack of pain in the precordium. His lungs at the time were clear and I felt that there had been a coronary thrombosis. I did not think that there was evidence for atelectasis or pneumonia, and did not believe that a pulmonary condition was playing any part in the symptoms. I did not see him again.

CLINICAL DIAGNOSES

Coronary thrombosis
Carcinoma of the rectum

DR PAUL D WHITE'S DIAGNOSES

Hypertensive coronary heart disease
Coronary artery narrowing due to atherosclerosis
Aortic stenosis
Pulmonary infarction from embolism?
Cystitis
Pyelitis?
(Carcinoma of the rectum)
Paroxysmal auricular fibrillation
Angina pectoris
Intermittent claudication

ANATOMIC DIAGNOSES

(Carcinoma of the rectum)
Operative wound. Combined abdominopelvic resection of the rectum with colostomy
Pulmonary embolism, bilateral
Coronary thromboses with myocardial infarction, old
Pulmonary tuberculosis, bilateral, active
Pleuritis, chronic fibrous, bilateral
Arteriosclerosis, marked coronary and aortic, moderate renal

Pylonephritis, slight
Cystitis moderato

PATHOLOGIC DISCUSSION

DR. MALLORY The autopsy showed that Dr. White was correct in predicting that no acute coronary thrombosis would be found. The left coronary artery was completely occluded however along with its major branches, but the occlusion was evidently very old. The descending branch of this artery was reduplicated and was represented by a small obliterated cord-like vessel and a somewhat larger almost completely closed one. The circumflex branch of the left was also completely closed. The right coronary was narrow but not obliterated. There were three small separate areas of infarction all of them old and completely scarred. In one of them the scar tissue was rather vascular and it is conceivable it may have developed at the time of the first operation, at any rate it seemed consistent with a duration of about a month. The other scars were evidently of much longer standing. We also found pulmonary emboli. He had an embolus to each of the lower lobes, the one on the right side being evidently much older than the one on the left, so I think perhaps the attack of right chest pain after the operation was due to the embolus.

The immediate cause of death was not entirely certain. He undoubtedly had a bad heart but we found one other totally unsuspected complication that I am sure played a significant rôle. The upper half of each upper lobe was completely consolidated with old tuberculosis and there were fresh foci of tuberculosis throughout both lungs. If Dr. King had had a chance to examine him at an earlier stage before the operation, I am sure he would have found something more definite. The aortic valve was described as not stenotic but the operator made note that the commissures and the valve margins were thickened and he measured the circumference as only six centimeters so that in spite of his statement I believe there was a slightly stenotic but not a massively calcified valve.

A PHYSICIAN May I ask Dr. White a question as regards postoperative fluids in cardiac patients? What is your opinion of the method of giving them, intravenously or hypodermicly?

DR. WHITE If as in this man patients show easy induction of angina pectoris or if congestive failure is impending I think extra fluid should be given slowly and not rapidly. I should think subcutaneous hypodermolysis is wiser in such cases than rapid intravenous injection.

The patient had always lived a vigorous life and had eaten heartily of a well seasoned diet with only occasional gastrointestinal upsets until one year before entry. At this time he began to have more frequent similar upsets, which assumed the character of gnawing and burning sensations in the epigastrium, rarely occurring under two hours after a meal and usually appearing at or after going to bed. This discomfort was somewhat relieved by further ingestion of food or fluid. Three months ago he consulted a physician who found something wrong with his stools and told him he had an ulcer although no x-ray was taken. He was given iron pills and a powder to take every four hours. He remained in bed for two weeks, adopted a bland diet, and at the end of a month was almost completely relieved of his symptoms. Thereafter he returned to work but had very little success. For several years he had been informed by his employers that his work was becoming poor and that he frequently made mistakes indicative of poor judgment. Following his return to work his attempts to obtain business were unsuccessful. He began to look sallow and his weight which had been 250 pounds fifteen years before entry and had gradually diminished to 200 one year ago, now became approximately 175 pounds. Six days prior to admission he visited his daughter who stated that he looked weak, pale and listless. His appetite was poor and contrary to his previous assertive manner, he was very much subdued. He went to bed and appeared to remain asleep ever since. He was aroused only with difficulty, was rather restless but uncommunicative and his skin was cold and clammy.

For years he had been told that his blood pressure was consistent with his age but eight months ago it was said to be 220.

The patient's father and brother had both had "ulcers of the stomach." His mother had had Bright's disease.

Physical examination showed a pale, slightly obese elderly male in restless coma. The mucous membranes were pallid, the tongue dry, and the breath had no characteristic odor. The pupils were unequal, the right being larger than the left. They reacted poorly to light. The lungs were clear. The heart extended 8 centimeters to the left of the midsternal line and 2 centimeters to the right. The rhythm was totally irregular and no murmurs were audible. The blood pressure was 120/80. The abdomen was large and flaccid. No masses were palpable nor was there evident local spasm or evidence of tenderness. A rectal examination showed a moderately enlarged prostate but no palpable masses. The examining finger was covered with blood stained fecal material. A neurologic examination was negative.

The temperature was 100.8°, the pulse 100. The respirations were 30.

CASE 22172

PRESENTATION OF CASE

A seventy three year old retired American insurance agent was admitted in coma.

Examination of the urine showed a specific gravity of 1.014 and there was no sugar, albumin, or diacetic acid. The sediment was negative. The blood showed a red cell count of 2,820,000, with a hemoglobin of 60 per cent. The white cell count was 19,100, 90 per cent polymorphonuclears. A Hinton test was negative. The nonprotein nitrogen of the blood was 120 milligrams per cent. A fasting blood sugar was 159 milligrams. A lumbar puncture showed clear colorless fluid with an initial pressure of 50 millimeters. The ammonium sulphate test was negative and there were two cells per cubic millimeter. The total protein was 58 milligrams. An electrocardiogram showed auricular fibrillation with moderate left axis deviation. S_2 and S_3 were prominent. There was a deep Q_4 and inverted T_4 .

The patient continued comatose and two other urine specimens showed no significant abnormality. On the second day the nonprotein nitrogen of the blood was 153 milligrams. The temperature subsided to 99° but the patient did not regain consciousness. He died on the second hospital day.

DIFFERENTIAL DIAGNOSIS

DR ALLEN G. BRAILEY. I think it is a very interesting case, and with this confusion of signs and symptoms one wishes one could rely on the old diagnosis of "complication of diseases." I think the place to begin is at the end. A man seventy-three years old dies in coma after five days to a week. Most of the causes of fatal coma are pretty easily eliminated. There is no evidence of trauma, for instance, and poisoning seems to be out of it. He has lost blood, he has anemia, the white count raised, but he certainly did not die of blood loss. Then there is a cerebral accident. It seems to me the onset of the coma was too slow for ordinary cerebral accident. The neurologic examination was negative except for minor differences in pupils. The spinal fluid was essentially normal. The total protein was 58. The pressure was 50 millimeters, which is very low. I do not know how to interpret either one of these figures unless they are the result of dehydration in a man who has been asleep for five or six days, and has had very little fluid. At any rate I think it is unlikely that his coma was due to any intercerebral condition. I think diabetes is pretty well ruled out. There is no characteristic odor to the breath. The blood sugar is somewhat raised, but not enough to be significant.

However, this is a very characteristic picture of uremic coma. He does not have convulsions but is restless. He had previous loss of appetite. In fact, going over the past history, for some time he has been under the weather. He has been losing weight in significant fashion for a year and there has been less efficiency at business. Then, also, he is anemic. The anemia may well be bleeding from the intestinal tract

which is probably due to colitis or ileitis which is so common with uremia. Of course uremia with a nonprotein nitrogen of 120 scarcely can be due to anything but chronic kidney disease. It occurs with prolonged vomiting in high intestinal obstruction but there is no reason to suppose that is the case here.

There are some things against this picture. If he has chronic kidney disease presumably he has had high blood pressure for some time and other evidence of renal and vascular damage. The record says that eight months ago the pressure was 220 but the one taken in the hospital was normal. The heart is described as small, — so small I think he undoubtedly has an emphysema and the percussion was unreliable. Still it must be admitted there is no evidence of its being enlarged. Then, of course, he had no convulsions. His urine on three examinations was normal. As a matter of fact they were not normal. The only one we have accurately reported is the first, with a specific gravity of 1.014. He is an old man and probably had taken very little fluid for five or six days and he is obviously dehydrated, so that the specific gravity of 1.014 is very significant of inability to concentrate. It is interesting that he has no albumin, no blood and no casts, it is unusual but not unheard of and does not make me change my mind about the diagnosis. I think there are a lot of contradictory statements here but I think he has had kidney disease of long standing and that he has uremia with colitis or ileitis, or both.

What other things do we have to consider? His doctor said he had an ulcer.

But the story of ulcer so far as it goes is not typical. He has had some gnawing, burning epigastric discomfort daily for a year, occurring for the first time in an old man. It is not well relieved by food. To be sure he gets better when he goes to bed with a bland diet and rest, but almost any stomach condition will improve under these conditions. He may have an ulcer but I do not feel obliged to suppose so. I think his symptoms can be better explained on the basis of uremia. Now as to carcinoma, he is an old man who has lost weight, who has anemia and bloody stools, but again I prefer the diagnosis of uremia with gastrointestinal bleeding.

What is the matter with his heart? He may perfectly well have had coronary accident. We notice the blood pressure is lower than it was said to have been. He has leucocytosis and fever. In fact, coma may conceivably be due to emboli from the left auricle. But the electrocardiogram does not indicate coronary occlusion. I suppose he probably does have some infection to account for fever and leucocytosis perhaps associated with the colitis, which I think he has. Also he may very well have a small amount of bronchopneumonia.

DR TRACY B. MALLORY. I might again ask if there are any alternative diagnoses.

DR WYMAN RICHARDSON. I suspect this man

also has a duodenal ulcer. I should like to inquire about the danger of treating an old man with duodenal ulcer with that large amount of alkali particularly if he has renal disease, vascular nephritis.

DR. MALLORY: I do not know how to answer that.

DR. WILLIAM B. BREED: I think that one cannot dismiss the diagnosis of carcinoma of the stomach here. It is of only a year's duration and we know of many cases of cancer of the stomach who have over a short period symptoms suggesting ulcer. He has lost a great deal of weight which is difficult to explain entirely on the basis of kidney disease and I think we should not lose sight of the possibility of cancer of the stomach.

DR. EARLE M. CHAPMAN: Will Dr. Breed explain the final episode with brain metastases of carcinoma.

DR. BREED: Certainly not.

CLINICAL DIAGNOSES

Chronic nephritis.

Uremia.

Gastrointestinal bleeding.

DR. ALLEN G. BRAILEY'S DIAGNOSES

Chronic nephritis

Uremia.

Gastrointestinal bleeding, probably from the colitis of uremia.

ANATOMIC DIAGNOSES

(Uremia.)

Nephritis, chronic vascular

Duodenal ulcer, chronic, without perforation

Cardiac hypertrophy, hypertensive

Arteriosclerosis, moderate aortic and coronary

Cholelithiasis

Cholecholelithiasis.

Pulmonary edema and congestion bilateral

Cystitis, acute localized

Dilatation of the esophageal hiatus

Operative scar Amputation of the distal phalanx of the right first finger

PATHOLOGIC DISCUSSION

DR. MALLORY: This man showed a very large penetrating ulcer on the posterior duodenal wall which had burrowed into the pancreas. He showed a greatly hypertrophied heart—Dr. Brailey was wise in questioning the apparent facts in the record. It weighed 650 grams which is double the normal. His kidneys weighed 325 grams, which is the lower limit of normal for a man, and they showed a little scarring on the surface but the cortex measured 5 millimeters which is pretty good for anyone of seventy. Microscopically, they showed very definite changes in the arteries and a few changes in the glomeruli which are consistent with long

standing hypertension, but they were not the kidneys that one would expect to find in a patient in uremia. He still had rather too much gross kidney substance for death from vascular nephritis and they also failed to show one other thing which is probably of some importance. One of the first clinical signs of insufficient renal function, whatever the origin is lack of tubular function, in other words, lack of concentration. Drs. Wilson and Kimmelstiel in going over 100 cases of vascular nephritis at the Boston City Hospital, found that the best correlation they could work out between the anatomic findings in the kidney and the functional evidence of renal failure depended upon the observation of dilatation of the tubules. Practically no cases showed real evidence of renal failure unless the tubules were fairly markedly dilated and hyperplastic. This man showed absolutely no dilatation of the tubules so I should say that they were not the kidneys that I would expect to have produced uremia. Recently Dr. Castleman has run across in Scandinavian publications several reports of uremic states following hemorrhage from the gastrointestinal tract. A man named Meyler* has reported six cases of impending or established uremia with a nonprotein nitrogen over 100 in patients with severe gastrointestinal hemorrhage. Some of these cases came to autopsy and were found to have relatively normal kidneys. Some recovered following appropriate therapy and the signs of renal failure disappeared.

I am inclined to raise the question concerning this case today whether we are not dealing with a synergistic effect of mildly damaged kidneys plus at least a moderate amount perhaps—we are not sure—a very considerable amount of gastrointestinal hemorrhage whether the hemorrhage from the gastrointestinal tract may not actually have played a rôle in producing the uremia. It is not an entirely satisfactory case because we did not have permission to examine the head.

A PHYSICIAN: Such an effect would be explained on the basis of damaged circulation of the kidney?

DR. MALLORY: Yes the mechanism is rather uncertain and although there are a considerable number of reports of the condition of nitrogen retention associated with hemorrhage, the various authors who have reported the cases differ widely in their theories of the pathogenesis. On the whole they think dehydration is most important and that anemia can play some rôle but a relatively unimportant one.

DR. GEORGE W. HOLMES: I have seen with Dr. C. M. Jones two patients who had duodenal ulcers and who illustrate what Dr. Richardson has said. Each of them had some kidney damage and as soon as they were placed upon an alkali diet their condition became more serious.

SERUM TREATMENT OF LOBAR PNEUMONIA

IMPROVEMENTS in the concentration of anti-pneumococcic serum, chiefly those suggested by Felton, have resulted in establishing the value of serum in the treatment of certain cases of lobar pneumonia. With accurate diagnosis, with proper selection of cases and with adequate doses of potent serum there seems to be little or no doubt but that the mortality in over 50 per cent of all cases of lobar pneumonia can be nearly cut in half. The importance of serum therapy as a life-saving measure is forcefully brought out by Heffron¹ who states that over 18,000 lives in the United States might be saved annually by this method of treatment. This figure is based on an estimated annual total of approximately 128,000 cases of lobar pneumonia and 4,000 cases of bronchopneumonia, all due to Types I and II pneumococci.

Until quite recently this method of treatment has been considered possible only in the larger medical centers and there only in the larger hospitals. The Massachusetts Pneumonia Study,

financed by the Commonwealth Fund and carried out from 1931 through 1935 by the Massachusetts Department of Public Health, has shown that equally successful results can be obtained in smaller communities and by physicians without hospital connections in the larger centers, provided typing facilities are available and provided the treatment is properly carried out. Based on these findings, the Massachusetts Department of Public Health has recently announced its willingness to supply all physicians in the Commonwealth with antipneumococcic serum, subject to certain reasonable restrictions. Similar action has been taken by the Departments of Health of Connecticut, New York State and Detroit. A valuable, but expensive, therapeutic agent is thus made available and the responsibility for its judicious use falls entirely upon the practicing physician.

As an aid in properly discharging this responsibility a small book, "Lobar Pneumonia and Serum Therapy", recently published by the Commonwealth Fund, should prove invaluable. The authors, Dr. Frederick T. Lord and Dr. Roderick Heffron, are well qualified—the former being a member of the Massachusetts Advisory Committee on Pneumonia and the latter Field Director of the Massachusetts Pneumonia Study. The important questions of diagnosis, selection of cases, precautions and methods of treatment are simply and briefly, but adequately, discussed. The success of serum therapy in lobar pneumonia depends, in a large measure, upon its intelligent use. The text of this handbook is based, chiefly, on data from the Massachusetts Pneumonia Study, a highly successful five-year experiment, and the book itself cannot be recommended too highly to those who aim to make the best use of a most important addition to their armamentarium.

PROBLEMS OF THE FLOOD

THE devastating floods which inundated parts of fourteen states in March gave rise, naturally, to a considerable degree of alarm concerning the hazards to health which might follow in their wake. Apprehensions were expressed by many individuals, even those living remote from the flooded districts, of a menace to health in the subsiding waters, a rush for typhoid vaccination was experienced and many families and even physicians prescribed the consumption of raw fruits and vegetables, regardless of their source.

It is natural that the specter of typhoid fever should arise when vast areas of settled country are covered by possibly polluted waters. Undoubtedly countless cesspools and

privies have been irrigated by the swollen rivers. Two factors of safety however, lie in the incalculable dilution which the contents of contaminated feci have experienced, and the fact that in most sections, at least, municipal water supplies have remained unpolluted. As a state health official recently pointed out, all public water supplies in Massachusetts were examined following the floods, the only one showing any suspicion of contamination coming from outside the flood areas.

According to the statement of this same official, the Massachusetts floods presented a problem of relief rather than of public health administration, although the Department of Public Health discharged its obvious duties immediately, efficiently and conservatively. Actually exposure and destitution provided the immediate health hazards, pneumonia constituted a graver risk than did typhoid fever and the pressing need at the time was for food shelter and clothing.

Continuing problems are being met as rapidly as possible. The debris is being cleared away and homes are being renovated. Roads are being opened and bridges replaced in order that life may resume its normal course. In some sections arable lands have been stripped of their top soil and left barren, in others the fields have been enriched by the deposit of silt left upon them. As Commissioner Chadwick has indicated however, these newly dressed fields must be cultivated and sown as soon as possible, lest the drying winds of summer again scatter the soil abroad before the roots of a new crop have anchored it to its place.

TUBERCULOSIS OUTBREAK IN AN ACCREDITED HERD

AN unexplained extensive outbreak of tuberculosis in the Government's herd of dairy cattle at Beltsville, Maryland is being investigated by the United States Department of Agriculture, according to a recent release. In this outbreak eighty two positive reactors and eleven suspicious animals were discovered in a previously clean herd of 378 animals. Of thirty-one reactors and suspects slaughtered at the time of this report, twenty five showed tuberculous lesions practically all of these being in cervical and thoracic lymph nodes.

This herd has been for eighteen years in an accredited status. In April, 1935 on a periodic test, one animal was regarded as suspicious. A ninety-day retest in July showed three reactors, a further retest in October disclosed one infected animal. Reactors appeared in seven of eight buildings in January, only the bull barn escaping infection. For seven years the herd has been maintained almost entirely by replacements raised on the farm, the few cattle from

outside sources having come from accredited herds.

The theory of accreditation by herd or area eradication, is eventually to establish and maintain a tuberculosis free cattle population. If bovine tuberculosis could be completely wiped out, there would, in theory, be no source for further infection and the millennium would be reached, in this respect at least. Complete eradication however is obviously difficult of achievement and similar outbreaks of unknown source, in accredited herds have not been unknown. An accredited herd or an accredited area is a laudable ambition but the goal once reached cannot be accepted with complacency, for continued enjoyment of it is at the cost of eternal vigilance.

A tuberculosis free herd may become in time, a highly susceptible herd and frequent retests with ideal conditions for isolation and segregation are necessary for its maintenance.

TREATMENT OF CHRONIC HEART DISEASE COMPLICATING PREGNANCY

As is to be expected, treatment of cardiacs in pregnancy is based chiefly on (1) preventing heart failure, (2) recognizing it early if it occurs, and (3) treating it adequately

Though the great majority of failures occur in the last trimester of pregnancy, the rule that

³A series of short selected articles by members of the Section is being published weekly
Comments and questions by subscribers are solicited and will be discussed by members of the Section

any cardiac may develop heart failure at any time during pregnancy or puerperium must be appreciated Clearly every human being who has heart disease should be under medical supervision, and part of the supervision of married women of child-bearing age who have heart disease should be specific instruction to report at once if pregnancy is suspected A suitable régime should be instituted immediately

The management of cardiacs is based, in general, on a study of unsuccessful cases The commonest cause of failure is accumulating fatigue Therefore, a schedule of regular hours of rest at night and for one or more periods during the day is essential Patients should be instructed never to break these fundamental rules under any circumstances The nature and duration of house or other work and of walking, the number of flights of stairs each day, should be carefully discussed with the patient and regulated Clearly no set rules can be made that are appropriate to all women In general, I have never seen any real harm come from restriction of activity and I have seen much harm from failure to control activity adequately Many failures could be averted if patients were carefully instructed on these simple matters and persuaded to follow their instructions The commonest causes for breaking these rules and allowing fatigue to occur are the following sickness in the patient's family, journeys, shopping trips, moving the household either to or from a summer home or to another home

Next to balancing rest and exertion, diet is probably the most important single factor Proper diet should cover the following points (1) weight control Weight reduction is of immense benefit to obese cardiacs Patients who are not obese should not be allowed to gain more than the standard amount during pregnancy Meals should be regular and at no time should a patient be allowed to gorge (2) Fluid intake should be controlled Excessive fluids particularly must be avoided where heart failure is present or feared (3) Adequate nutrition and (4) control of anemia Fruits meats, vegetables and milk must be taken to aid in maintaining a satisfactory high red blood cell count and hemoglobin Anemia seems to be an especially severe burden on cardiac patients in pregnancy, and it should be treated vigorously by drugs if diet control is insufficient There is no reason why the modern accepted requirements for nutrition of the mother cannot be made to fit the requirements of the cardiac patient

Oral sepsis may be a heavy burden and should be searched for and treated reasonably if found

The rôle of infection in producing heart failure in pregnancy is as follows the typical rheumatic heart disease patient in pregnancy has acquired a satisfactory immunity to recur-

rence of the active rheumatic disease. This is a fortunate and not thoroughly appreciated fact. We do not need to dread a flare-up of rheumatic carditis. It is an extremely rare occurrence during pregnancy. Intercurrent infections—tonsillitis, grippe and the like—occur more often than not at some time during a pregnancy. They have a certain danger. It is remarkable how well cardiac patients tolerate these illnesses if they go to bed at the onset of symptoms and stay there until the infection is thoroughly over, then slowly increase their activities, taking a week or two to return to the level of physical exercise allowed before the infection. They seldom develop failure. If these precautions are neglected, the average upper respiratory infection may readily cause heart failure in a cardiac during pregnancy.

Patients with cardiac disorders must report for examination at least once a week. The main object of these visits is to detect early signs of failure. Though refinements of observation for example changes in the movements of the chest wall with respiration and careful vital capacity determinations may in some cases warn of a threatening failure, the earliest reliable signs of heart failure are persistent râles at the lung bases posteriorly. If a cardiac develops these rules during pregnancy, she should be considered to be in failure.

Failure means that the patient has suffered serious damage. The usual treatment for heart failure should be started and *the patient should be in bed or in bed or chair until delivered* no matter how promptly and completely the signs of failure may clear with treatment. Failure in any pregnancy also means that the patient faces approximately a death rate of 25 per cent if she tries to go through another pregnancy.

An immense amount of ingenuity can profitably be used in selecting type and time of delivery in selecting the form of anesthesia and in its administration, in careful preparation and nursing of the patient through labor, delivery and recovery from operation. No set rules can or should be followed. Fortunately granted skillful delivery and aftercare, few cardiacs fail for the first time during or following delivery. The emphasis of the treatment of heart disease during pregnancy should be on careful early diagnosis of the heart disease and relentless control of the cardiac patient throughout the whole of pregnancy, delivery and puerperium. I have deliberately accented these apparently simple details of prenatal care of the cardiacs since these are by all odds the most important part of the problem.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning April 24

Berkshire

Thursday April 30 at 4 30 P.M. at the House of Mercy Hospital Pittsfield. Subject Kidney and Bladder Diseases A (Surgical)—Hematuria Its Significance in Surgical Diseases of Kidney and Bladder. Instructor F. H. Colby. Melvin H. Welker Jr., Chairman.

Bristol North

Wednesday April 29 at 7 30 P.M. at the Morton Hospital, Taunton. Subject Pediatrics (Medical)—The Neonatal State. Instructor W. R. Sisson. Arthur R. Crandell, Chairman.

Bristol South (New Bedford Section)

Friday May 1 at 4 00 P.M., at the St. Luke's Hospital New Bedford. Subject Diseases of the Liver—Hepatitis and Painless Jaundice. Problems in Diagnosis and Treatment. Instructor C. Frothingham. Harold E. Perry, Chairman.

Franklin

Wednesday April 29 at 8 00 P.M. at the Franklin County Public Hospital, Greenfield. Subject Dermatology—Ten Common Skin Diseases—Diagnosis and Treatment (1) Impetigo Contagiosa (2) Scabies (3) Acne Vulgaris (4) Psoriasis and Seborrheic Dermatitis, (5) Epidermophytosis (6) Herpes Simplex and Zoster (7) Eczema, (8) Erythema Multiforme (9) Verruca Vulgaris and (10) Dermatitis Medicamentosa and Dermatitis Venenata. Instructor J. H. Blaisdell. Helbert G. Stetson, Chairman.

Middlesex East

Wednesday April 29 at 4 00 P.M. at the Melrose Hospital Melrose. Subject Kidney and Bladder Diseases A (Surgical)—Hematuria Its Significance in Surgical Diseases of Kidney and Bladder. Instructor G. O. Prather. Joseph H. Fay, Chairman.

Middlesex North

Friday May 1 at 7 30 P.M. at the Lowell General Hospital Lowell. Subject Cancer of Breast and Uterus. Instructor J. V. Molg. Leonard C. Dursthoff, Chairman.

Norfolk

Friday May 1 at 8 30 P.M. at the Norwood Hospital Norwood. Subject Lung Diseases—(a) Significance of Symptoms and Signs in Chronic Lung Diseases Tuberculosis Bronchiectasis etc. (b) The Value of Surgery in Above Disease Problems. Instructor S. H. Proger and R. H. Sweet. H. B. C. Riemer, Chairman.

Warcester (Milford Section)

Wednesday April 29 at 8 30 P.M. at the Milford Hospital Milford. Subject Arthritis—(a) Medical Care of Patient in the Home.

(b) Orthopedic Treatment in Hospital and Aids in Home Treatment Instructors R T Monroe and W T Green Joseph I Ashkins, Sub-Chairman

APPLICATION FOR MEMBERSHIP IN THE ESSEX NORTH DISTRICT MEDICAL SOCIETY

New England Journal of Medicine,

According to the resolution adopted at the last Council meeting, I am sending you the names and addresses of an applicant for Fellowship and five sponsors which are to be published three weeks prior to the Censors' meeting

Applicant — Dr Lawrence Murphy, 216 High Street, Newburyport, Mass

Sponsors—Dr Frank W Snow, 24 Essex Street, Newburyport, Dr R L Toppan, 148 High Street, Newburyport, Dr C F A Hall, 210 High Street, Newburyport, Dr L C Peirce, 279 High Street, Newburyport, Dr R C Hurd, 244 High Street Newburyport.

In compliance with the By Laws of the Society (Chap I, Sec 1, Chap V, Sec 1, and Chap VII, Sec 5) the application and letters of the sponsors have been sent to Dr Fitz, Chairman of the Committee on Medical Education and Diplomas

E S BAGNALL, M D

April 14, 1936

MISCELLANY

\$10,000 PRIZE FOR RELIEF OR CURE OF DISEASES OF REPRODUCTIVE ORGANS

A prize of more than \$10,000 will be awarded in 1940 and every seven years thereafter by the American Academy of Arts and Sciences in Boston for 'outstanding work with reference to the alleviation or cure of diseases affecting the human genital organs' The award is to be known as the Francis Amory Septennial Prize, since it is made possible by a fund established by the will of the late Francis Amory of Beverly, Massachusetts In case there is work of a quality to warrant it, the first award will be made in 1940 It rests solely within the discretion of the Academy whether an award shall be made at the end of any given seven year period, and also whether on any occasion the prize shall be awarded to more than a single individual

While there will be no formal nominations, and no formal essays or treatises will be required, the committee invites suggestions, which should be made to the Amory Fund Committee, care of the American Academy of Arts and Sciences 28 Newbury Street, Boston — *The Diplomat*, April 1936, page 136

DR JIM, HEALER FOR 1,000,000 ZULUS, RETURNS FROM THIRTY FIVE YEARS IN SOUTH AFRICA

"Dr Jim," physician for over thirty five years in Durban, South Africa, arrived in Boston April 14

In Africa, where he founded the first hospital for Zulus in 1899, that is his title His hospital is the "House That Jim Built," and his wife, a trained nurse, is "the Princess"

His New England friends who were skeptical when he left here as a young missionary doctor, knew him as Dr James B McCord of Oakham, Mass

"There is only about one doctor to every million people in Africa," Dr McCord informed us

To meet this great medical need, Dr McCord is training the black to care for his own, as well as relieving sickness and suffering in his hospital

Last year, after a seventeen year struggle, Dr McCord induced the South African Government to put through a plan whereby young Zulus will receive medical education in the South African Native Colleges — *Boston Transcript*, April 14, 1936

AMERICAN COLLEGE OF PHYSICIANS

At the recent annual meeting of the American College of Physicians, held in Detroit, the following members assumed office or were elected for the year 1936-1937

President, Ernest B Bradley, Lexington, Ky

President Elect, James H Means, Boston

First Vice President, O H Perry Pepper, Philadelphia

Second Vice-President, David P Barr, St. Louis

Third Vice-President, Walter L Blerring, Des Moines

Secretary General, William Gerry Morgan, Washington, D C

Executive Secretary, E R Loveland, Philadelphia — *The Diplomat*, April 1936, page 134

ANNUAL JOINT MEETING OF AMERICAN ASSOCIATION OF MILK COMMISSIONS AND CERTIFIED MILK PRODUCERS

Immediately preceding the eighty seventh annual meeting of the American Medical Association, the American Association of Medical Milk Commissions will hold its annual joint meeting with the Certified Milk Producers' Association of America, May 11-12, at the Hotel Baltimore, Kansas City, Mo

In addition to reports from the eighty six Medical Milk Commissioners in the United States, Hawaii and Canada, addresses will be delivered by a number of prominent physicians and scientists These will include Dr Milton J Rosenau, formerly head of the Department of Preventive Medicine and Hygiene at the Harvard Medical School, President of the American Association of Medical Milk Commissions, Dr Boyd S Gardner of the Mayo Clinic, Rochester, Minn, Dr Paul J Zentay, Secretary, St. Louis Pure Milk Commission, Dr Harold L Barnes, Chairman, King's County Medical Milk Commission, Brooklyn, N Y, Dr Oscar Reiss, Secretary, Los Angeles County Medical Milk Commission, Dr Edwin T Wyman, Boston Medical Milk Com

mission, and Dr Hugh L. Dwyer Medical Milk
Commissioner Jackson County Medical Society Kan-
sas City Mo

WHY TRY TO PERSUADE THE PUBLIC?

Today medicine is where theology was when Got-
tenberg invented printing

The Bible, which was the specios and sacrosanct
possession of a small highly specialized group the
clerics soon became after the invention of print-
ing a book about which anybody could have an opin-
ion—almost everybody did have an opinion—and
the result of the clash of beliefs in extreme in-
stances resulted in the overthrow of governments
and in wars. By virtue of the Bible becoming ac-
cessible to the public, civilization was profoundly
changed.

We live today in another age of change—change
which is affecting medicine along with everything
else. The loafer on the street corner considers
himself competent to express an opinion on the gold
standard. What is still worse competent men in
one field consider themselves qualified to express
opinions in another field in which they are not
competent.

Thousands of medical men trained in our medical
schools are occupied in rendering a partial and
limited knowledge of medicine widely available to
the public, as employees of official and voluntary
health organizations or as popular writers on medi-
cal subjects. True they are imparting only a smat-
tering. Their work is open to the criticism that it
indirectly encourages self-diagnosis and self-medica-
tion. The increasing growth of this movement can
not be stopped by condemning it, if indeed it should
be condemned. A little learning is not a dangerous
thing to a man who knows it to be little. If organ-
ized medicine co-operates and itself becomes vocal
we will not be overwhelmed in the sea of created
opinion which if it be not altogether opposed to
the purposes of organized medicine is in substance
indifferent to them.

Justice Oliver Wendell Holmes said: The best
test of truth is the power of thought to get itself
accepted in the open market.—*Public Relations*

THE CONTROVERSY OVER WHETHER ALEXIS ST MARTIN EVER VISITED ST LOUIS

For a considerable time the story that Alexis
St. Martin visited St. Louis has been disputed.

To the *Bulletin of the Medical Library Association*
for February 1938 there is a copy of an editorial
(St. Louis Med. & Surg. J. [July] 1856) found by
Miss Harriette Worthmauer, Assistant Librarian of
the Library of the St. Louis Medical Society which
establishes the fact that Alexis St. Martin did visit
St. Louis in charge of Dr. Bunting.

The text of the editorial is as follows:

ALEXIS ST MARTIN

Dr. Bunting late of the British army in Canada
recently visited our city having in charge St. Martin
so well known in this community and by physio-
logists everywhere, as the subject on which our
late distinguished fellow citizen, Dr. Beaumont, per-
formed his celebrated experiments on the physiology
of digestion. While here Dr. B. exhibited this unique
specimen in the amphitheatre of the St. Louis Medi-
cal College and performed a few so-called experi-
ments before a large number of physicians and other
scientific gentlemen of the city at the close of
which a collection was taken up for the benefit of
his patient. It is now some thirty five or six years
since St. Martin received a gunshot wound in his left
side, which has left a large fistulous opening into
his stomach through which the rare opportunity is
afforded of examining the contents of that organ
during the various stages of digestion. At present,
he is 53 years old is in good health and in the full
and vigorous possession of all his functions seeming
to suffer but little inconvenience from his wound.
When the bandage is removed and the side exposed
the inner coat of the stomach slightly protrudes
presenting a red almost scarlet appearance.

It is understood that Dr. Bunting and his attaché
are on their way to Europe where it is to be hoped
the case will fall into the hands of some of the
eminent physiological observers of the old world
who are capable of using it for the advancement of
science. Such a case has never before occurred and
may not occur again yet it is greatly to be regretted
that as yet but comparatively little practical good
has resulted to physiological science from it. In the
exhibition which we witnessed it was evident that
the object was more to realize money than to pro-
mote science, but we hope that hereafter a different
course will be pursued and that the profession will
yet have the benefit of all the light that this rare
case is capable of shedding on the interesting sub-
ject of digestion. We therefore earnestly desire
to hear from St. Martin again.

From this it can be seen that he came about
three years after William Beaumont's death which
occurred on April 25 1853.

CHILD HEALTH DAY

On April 13 President Roosevelt proclaimed May
1 as Child Health Day. The text of the proclama-
tion is:

Whereas the Congress by joint resolution of May
18, 1923 (45 stat., 617) has authorized and requested
the President of the United States to proclaim an-
nually May 1 as Child Health Day; and

Whereas the health and security of its children
are essential to the well being of this nation; and

Whereas it is advisable this year as we launch
the social security program to encourage by every
possible means the development of plans to pro-

mote maternal and child health, and to extend child welfare services

Now, therefore, I, Franklin D. Roosevelt, President of the United States of America, do hereby proclaim and designate the first day of May of this year as Child Health Day, and do urge all agencies, public and private, concerned with the health and welfare of children, on this day to study the plans for Federal, State, and local co-operation in promoting the health and security of children, to note the extent to which those plans have so far been put into effect, and to make arrangements for carrying their benefits to the children in every county in the United States

BOVINE TUBERCULOSIS IN CONNECTICUT

The U. S. Department of Agriculture has added Connecticut to its list of states practically free of bovine tuberculosis. This brings the number of states in the modified accredited area to thirty-nine.

Tuberculosis eradication work among the cattle in Connecticut was begun more than a quarter century ago and has been in progress in co-operation with the federal government since 1918. Recently New London, New Haven, and Fairfield counties were added to the official list of modified accredited counties in that state. Official tuberculin testing of cattle in other counties had been completed previously to an extent whereby these counties could be made modified accredited areas.

Co-operation of the livestock owners with state and federal officials made it possible to reduce the incidence of the disease, which formerly was rather widely prevalent. Before an area can be designated as modified accredited, the degree of infection among the cattle must be less than 0.5 per cent as shown by official tests.

When a state becomes a modified accredited area the most difficult part of the eradication work has been completed. However, it is necessary to prevent the disease from getting new footholds, officials explain. This is done by retesting the formerly infected herds at regular intervals and removing any diseased cattle found.—*Bulletin, U. S. Department of Agriculture*

CORRESPONDENCE

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

535 North Dearborn Street, Chicago, Illinois,

April 1, 1936

Managing Editor, *The New England Journal of Medicine*

In addition to the articles enumerated in our letter of March 4 the following have been accepted:

Abbott Laboratories

Ophthalmic Ointment Butesin Picrate 1% and Butesin 1%

Cheplin Biological Laboratories, Inc.

Cheplin's Sodium Cacodylate 0.05 Gm ($\frac{1}{4}$ grain), 1 cc

Cheplin's Sodium Cacodylate 0.1 Gm ($\frac{1}{2}$ grains), 1 cc

Cheplin's Sodium Cacodylate 0.2 Gm (3 grains), 1 cc

Cheplin's Sodium Cacodylate 0.3 Gm (5 grains), 1 cc

Cheplin's Sodium Cacodylate 0.5 Gm ($\frac{7}{8}$ grains), 1 cc

RECENT DEATHS

HILL—THOMAS CHITTENDEN HILL, M.D., formerly of Gloucester, Massachusetts, with an office at 270 Commonwealth Avenue, Boston, died at his winter home at Vero Beach, Florida, April 11, 1936.

Dr. Hill was born in Charlotte, Vermont, in 1871, and graduated from Vermont University and the University of Vermont College of Medicine. He subsequently studied at St. Mark's Hospital, London, England. Dr. Hill was a Fellow of the Massachusetts Medical Society, the American Medical Association, and the American College of Surgeons. His specialty was proctology. He was the author of the "Manual of Proctology" which passed through three editions and was translated into foreign languages. By reason of his standing in the specialty, he was elected to the presidency of the American Proctological Society and to the teaching staff of the Harvard Medical School.

Dr. Hill is survived by his widow, the former Mrs. Marion Whitin Brewer, two stepsons, Cyrus and Whitin Brewer, and two brothers, Monroe and Martin Hill, of Charlotte, Vermont.

McGRAW—ANDREW JAMES McGRAW M.D., of 93 Washington Street, Taunton Mass died April 20 1936 after a long illness

Dr McGraw was a native of Fall River the son of Hugh McGraw He graduated from the College of Physicians and Surgeons of Baltimore in 1906 and settled in Taunton soon after He joined the Massachusetts Medical Society in 1913 and was also a Fellow of the American Medical Association.

Dr McGraw became interested in civic affairs was a member of the School Committee for many years and served the City of Taunton as mayor for eight years. During the World War he trained at Plattsburg and was assigned to the 20th Ohio Infantry with which he went overseas, and was returned with the rank of major

His widow Mrs. Anna McGraw two sons John and Andrew of Taunton two sisters Mrs. R. E. McDonald and Mrs. Mary Perry of Westford and two brothers Edward McGraw of Westford and John McGraw of Ohio survive him

BULKELEY—FRANK S. BULKELEY M.D., of 111 Massachusetts died at the Ayer Hospital April 19 1936, after an extended illness. Dr Bulkeley was born in Ayer in 1879 the son of Joseph W. and Serena (Taft) Bulkeley After studying at Phillips Andover Academy he entered the Harvard Medical School graduating therefrom in 1902 and immediately afterward settled in Ayer He had served as a medical examiner of the North Middlesex District for twenty-four years.

Dr Bulkeley joined the Massachusetts Medical Society in 1903 and terminated his membership in 1918.

KELLY—JOHN S. KELLY M.D., of Quincy with an office on Harvard Avenue Allston died as the result of an automobile accident, April 20 1936

Dr Kelly was born in 1887 and graduated from the Middlesex College of Medicine and Surgery in 1921

His widow and three children survive him

NOTICES

THE HENRY JACKSON LECTURES OFFERED BY THE NEW ENGLAND HEART ASSOCIATION

These lectures will be given by Tinsley R. Harrison M.D., Associate Professor of Medicine Vanderbilt University School of Medicine at 4:45 P.M. on Thursday April 30 and Friday May 1 at the Boston Medical Library (John Ware Hall)

Subjects

1. The Pathogenesis of Circulatory Failure
2. The Principles of Therapy in Patients with Congestive Heart Failure.

Physicians and students of medicine are cordially invited to attend.

The annual business meeting of the New England Heart Association will precede the lecture on April 30.

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 P.M. on Thursday April 30 in the Amphitheatre of the Peter Bent Brigham Hospital Dr. Henry A. Christian, Physician-in-Chief, Hersey Professor of the Theory and Practice of Physiology in the Harvard Medical School, will give a medical clinic. To it are cordially invited practitioners and medical students

This will be the last clinic until the first Thursday in October

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12 staff rounds will be conducted by Dr. Christian.

REPORTS AND NOTICES OF MEETINGS

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

A meeting of the Middlesex South District Medical Society was held on March 18 1936 at St. Elizabeth's Hospital. The attendance was unusually large 125 members being present. The meeting was called to order by Dr. Remick, the president. He introduced Father Brennan who welcomed the members present, expressing his regret about the inclement weather and the pleasure of the hospital in offering its facilities to the District Society

Seven very interesting papers were presented by various members of the staff. Short summaries follow

ALEXANDER A. LEVI, M.D.

Secretary Middlesex South District

Dr. George F. Keenan Surgeon-in-Chief, East Surgical Service, presented a Case of Abdominal Pregnancy of Ovarian Origin. The condition was encountered as an unexpected complication in hysterectomy for uterine fibroids.

The patient presented no signs or symptoms of pregnancy. The Aschheim-Zondek test was negative. The classification of all types of extra-uterine pregnancy was briefly reviewed.

Specimens exhibited were a fibroid uterus, right ovary with placental attachment and invasion, and a four-month normal fetus

Dr. Edward J. O'Brien showed a most interesting case of Bilateral Pyonephrosis with a massive calculus in the left kidney with the lantern slide demonstration of the same.

It was the case of a girl twenty-six years of age who had a giant calculus of the left kidney with loss of function on this side, complicated by a massive pyonephrosis of the right kidney which filled the entire right side of the abdominal cavity to the extent that the gastrointestinal series demonstrated that the entire ascending colon and transverse colon were displaced to the left side of the abdomen. The stone was removed followed by

the return of function to the left kidney The right kidney was later operated on and drained with a view to restoring some of its function

Dr John E Burns gave a short talk on Bronchoscopy as an Aid in Diagnosis with Particular Reference to Pneumonography He showed several lantern slides illustrating the value of lipiodol in mapping out lung pathology

Dr John G Downing spoke of the present day status of Industrial Dermatitis, citing instances of various legal conditions in the different states He also spoke of the legal problems encountered in some cases here in Massachusetts, and discussed the various dermatoses as defined in law, with reference to a classification which he has compiled from personal cases and the literature, which is as follows

- 1 Mechanical or physical agents, i.e., abrasives, heat, cold, actinic rays, friction
- 2 Flowering plants and their products—resins, lacquers, wood dusts
- 3 Vital agencies
 - a. Bacteria, yeasts, molds
 - b. Members of the animal kingdom—mites, etc.
- 4 Chemical agents
 - a. Inorganic compounds—acids, bases, salts
 - b. Hydrocarbons and crude coal tar products—oils, tar, pitch, etc.
 - c. Other organic compounds

He then showed lantern slides depicting the patch test (which he explained), and also pictures of characteristic types of Industrial Eruptions

Dr Edward M Hodgkins stated that he was in the habit of regarding the space through which either direct or indirect inguinal hernia occurred as triangular, the boundaries being, the internal oblique and transversalis muscles above the lateral border of the rectus muscle and its fused sheath medially and the spine of the pubis and inguinal ligament below The triangle becomes dilated by atrophy and retraction medially of the internal oblique and transversalis muscles

The widening is when a large sac of long duration or a large recurrent sac has been pushing through Wearing of trusses over a long period likewise causes definite atrophy of muscles and widening of the triangle It is therefore impossible to do a repair by attempting to draw muscle over to the inguinal ligament without undue tension by the usual oft repeated catgut methods of operation Some type of living suture method must be used to build a new protective wall A method of using strips of fascia from the rectus sheath as sutures to span this space and build the new wall was described and illustrated with lantern slides An experience of ten years with huge primary and recurrent hernias was reported Fascia is autoplasmic, heals readily into contiguous structures and becomes perma-

nent tendinous grafts Previous publications with reported cases were cited as convincing evidence of the efficacy of this method The method is important in economic rehabilitation, as it places people back at work who would otherwise be dependent on family or charity

Dr John F Casey gave a brief talk on Peripheral Vascular Disease, particularly emphasizing the early symptoms and diagnostic points He felt that early diagnosis and early treatment would result in the saving of many extremities The Pa-va-ex machine was demonstrated at the close of the meeting

Dr Francis P McCarthy, Pathologist at the hospital, gave a report of a group of unusual and interesting cases with gross and microscopical pathological specimens

One unusual breast tumor, an adenomyxoma fibrosarcoma was shown This tumor was of twenty years' duration and began as an adenofibroma

A case of lymphosarcoma involving the mediastinal and retroperitoneal lymph nodes with diffuse involvement of both kidneys was demonstrated. The kidneys were tremendously enlarged, each weighing over 700 grams and were the only organs involved other than the lymph nodes

An embryonal sarcoma of the right kidney, in a child of two years, which involved a greater part of the abdominal cavity was also shown

A specimen of lung showing typical silicotic nodules in an advanced case of silicosis was demonstrated together with the microscopical sections

An enormous fatty cirrhosis of the liver weighing over 7000 grams and a large aneurysm of the ascending and transverse arch of the aorta were demonstrated

An interesting specimen of an adenocarcinoma of the stomach and a rheumatic heart, weighing 1120 grams, from an eighteen-year old boy who had rheumatic fever in early childhood, were demonstrated

THE FAULKNER HOSPITAL CLINICAL MEETING

The regular monthly clinical meeting was held at The Faulkner Hospital on Thursday afternoon, March 5, at 5 00 P M

One of the cases which had come to autopsy during the month was that of a male, forty-eight years of age, who presented a typical picture of infection involving the larynx Although diphtheria was suspected, the culture was negative Examination of the larynx showed a congested and swollen epiglottis and vocal cords It was not possible to see beyond the vocal cords A short time after the patient arrived in the hospital he coughed up a perfect cast of the trachea and beginning of the bronchi From this cast diphtheria organisms were obtained Despite large doses of antitoxin, laryngeal obstruction developed and a tracheotomy was done The patient succumbed from what appeared to be general

toxic reaction. At autopsy a typical picture of laryngeal diphtheria was present. Marked congestion and edema filled the alveolar spaces. From the lungs a culture of streptococcus viridans was obtained. In certain places in the lungs there was a hyaline-like membrane such as is found in cases of the epidemic disease generally called influenza, but the distribution of this membrane was different from that found in the epidemic disease. An interesting feature of the case was a leukocyte count of 17,400 with 92 per cent polymorphs which is rather high for infection with diphtheria and would not be expected in a streptococcus viridans which was the only other organism found at the autopsy.

The other case was that of a woman seventy-eight years of age who had a terminal infection with high fever gradually rising pulse rate and elevated respirations with a moderate leukocytosis. There were a few crackling rales at the base of one lung and it was felt without doubt that the case was one of terminal pneumonia in an old woman. This case demonstrates the value of having a post-mortem examination on all cases no matter how simple they seem, because there was no pneumonia. The cause of death was a staphylococcus aureus septemia with marked involvement of the heart muscle. Microscopic abscesses were found elsewhere especially one in the brain which was just about to burst through into the meninges and, had she survived a day or so longer it would have undoubtedly produced a staphylococcus meningitis. Another interesting feature in the case was the practically complete occlusion of the coronary arteries without pronounced cardiac infarction.

Following the presentation of these two cases Dr Richard C. Eley talked on the clinical applications of extracts obtained from the human placenta. He called attention to the fact that there were two extracts at the present time one a 2 per cent salt extraction with the resulting protein which had the power of neutralizing the poison of poliomyelitis preventing measles blanching the scarlet fever rash and neutralizing diphtheria toxin. Although this extraction has these four qualities, the practical application of it at the present time has been in the prevention of measles. He called attention to the fact that attempts to prevent measles had been tried by the use of serum from patients convalescing from measles adult human serum and adult human whole blood in addition to the use of this placental extract. The advantage of the placental extract is that it can be used in smaller quantities than either adult whole blood or adult serum. Since it is put out by the Commonwealth of Massachusetts ready for use, it is easier to obtain than the serum from a convalescent patient.

He then showed figures to demonstrate that this placental extract is more effective in preventing measles or making the disease milder than the serum or the whole blood. He called attention to the fact that if this placental extract is taken by mouth it will reverse the Dick and Schick tests

temporarily. Just what clinical application can be made of this has not as yet been decided.

He then called attention to another extract of the placenta which has a coagulating action upon human blood. He emphasized the importance of realizing that this coagulating action was not present in the extract of the placenta which is distributed by the Commonwealth of Massachusetts. The extract of the placenta used for the prevention of measles is sterilized by passing through the Berkefeld filter. The coagulating agent in the placental extract will not go through the filter and therefore cannot be sterilized. It is given by mouth and one of the difficulties is the tendency of the gastric juices to destroy it. The results upon children who are hemophiliacs have been very remarkable in many cases. In some cases it has not been so successful. In adults the results have not been so satisfactory as in children and it is felt that there is some point in regard to the destruction of the substance in the gastric juice which has not as yet been overcome. In addition to the value of this preparation in children with a tendency to bleed it has been successful in stopping the oozing from raw surfaces after adenoid operations thus saving the packing of the nasopharynx, stopping the bleeding from cleft palate operations and also stopping hemorrhage from the pockets from which teeth have been extracted. Some interesting results have also been obtained in cases of prolonged menstruation. Up to the present time the results on cases of purpura and leukemia have not been encouraging.

This extract of the placenta which contains the coagulant can be given by mouth intramuscularly or applied locally.

WILLIAM HARVEY SOCIETY

The William Harvey Society held its regular monthly meeting on February 14, 1936 with Dr Elmer W. Barron presiding. Dr L. Emmett Holt Jr., Associate Professor of Pediatrics at Johns Hopkins University School of Medicine spoke on the "Significance of the Fats in Infant Nutrition. High fat diets in infant feeding have been advocated periodically since Biblical times. A wave of enthusiasm for this type of feeding which spread to England and this country was started by Biedert in Germany in the latter part of the nineteenth century. In its trail came a reversal of feeding fats being deprecated and avoided because of their supposed tendency to produce diarrhea, their demonstrated inhibitory action on the stomach, a belief that they were responsible for certain types of anemia and that their prolonged use in large quantity might lead to the syndrome of fat intolerance. Particular opprobrium has been attached to the fat of cows' milk and, in the belief that fats are species specific, many attempts have been made to imitate the fat of human milk in artificial feeding. This doctrine has survived and finds expression in the current practice of feeding not more than 35 per cent of the calories as fat when cows' milk is used and also in

the use of various fat mixtures designed to imitate breast milk fat.

Dr Holt and his collaborators were led to question the soundness of these views. They undertook to re-investigate the question of the species specificity of milk fat and to make comparative studies of various fats in infants from the point of view of ease of absorption, of their inhibitory influence on the stomach, their supposed hemolytic effects and their internal utilization.

Observations on human milk fat indicated there was comparatively little species specificity. The fat could be greatly altered by changes in the character of the fat of the diet, this had been previously reported by Engel whose work was generally overlooked.

The conditions influencing fat absorption in general were studied. It was found that the size of the fat particles is not a factor of importance, the quantity of protein and carbohydrate present exert no appreciable influence, but minerals, particularly calcium in excess, may impair fat absorption.

The retention of different fats by infants was studied. These were selected with a view to demonstrate the effects of varying the composition of the fat. It was found that the completeness of absorption could be predicted within narrow limits from a knowledge of the component fatty acids. The shorter chain fatty acids were more readily absorbed than those with longer chains. The presence of an unsaturated linkage in the fatty acid chain favored absorption. The evidence as to whether more than one double bond was advantageous was not conclusive, but there was suggestive evidence that this was the case. No evidence was obtained that the volatile fatty acids are irritating or cause diarrhea, as had been claimed. It was found that several vegetable fats, notably olive oil and soya bean oil, were even better absorbed than average human milk fat. The "imitations" of human milk fat were not so well absorbed as the human milk fat itself. They represented little or no improvement over butter and one preparation was less well absorbed than butter. The differences in absorption found with normal infants on these various fats were not so great as to be of practical importance. In a series of premature infants, however, who are notoriously poor fat absorbers, the substitution of a more digestible vegetable fat for butter caused a significant increase in absorption which was promptly reflected in the weight curve.

It has been known for many years that fats inhibit the motility and secretion of the stomach. The phenomenon is due to a humoral mechanism released after fat enters the duodenum. Lim and others have extracted a chalone from the duodenum which is capable of producing this effect, when introduced into the circulating blood. Cameron and Tidwell in Dr Holt's laboratory made comparative studies of the inhibitory effect of different fats, and found that the fats which produced the greatest inhibition were those which were most readily assimilable. The purpose of this inhibitory phenom-

non remains obscure, but at least it does not appear to be harmful.

In the past it has been maintained that fats gave rise to increased blood destruction, although recent work has cast doubt upon this. The problem was restudied in Baltimore with the collaboration of Dr Josephs in a series of infants whose urobilin output was determined on various high fat diets. The response was uniform regardless of the type of fat used. The urobilin output rose promptly but within a few days it fell again, being maintained at a level almost twice as high as the normal for that individual. It did not at any time reach the high values found in infections or hemolytic anemias. The preliminary marked rise appeared to be due to a washing out of stores, since it could be produced by mineral oil alone. The protracted effect could not be produced with mineral oil. It is not proved that the sustained increase in urobilin output is due to blood destruction. Other evidence of blood destruction was not found, but by exclusion it would seem that a mild degree of increased blood destruction is responsible for the increased urobilin output.

Attempts were made to study the internal utilization of various fats in infants. Intravenous injections of various emulsified fats revealed no differences in the rate of removal from the blood. This may, however, have been due to the fact that in all instances egg lecithin was used as an emulsifying agent, giving the fat particles a uniform coating. Studies were also made by Nichols and Myers in Dr Holt's laboratory on the alimentary lipemic curve after the ingestion of various fats. When the quantity of fat ingested for the test is sufficiently large, a striking alimentary lipemia is exhibited by the infant. If, however, the infant is maintained upon a high fat diet for some days or weeks, the lipemic curve induced by the same test dose of fat gradually diminishes, as the organism acquires an increased ability internally to dispose of fat. This same phenomenon has been observed in animals by Bang and by Leites. Whether it is due to a "training" of the tissues to utilize fat or to some circulating hormone elaborated in larger quantities upon demand is still unsettled. In an infant adapted to utilize a large quantity of one fat, other fats were substituted for the test meal in the hope of detecting by variations in the alimentary lipemic curve, whether this fat-adapted state was specific for particular fats. No such specificity was demonstrated.

NEW ENGLAND ROENTGEN RAY SOCIETY

The February meeting of the New England Roentgen Ray Society was held at the Massachusetts General Hospital on the evening of February 21, 1936. After the brief business of the Society was over, Dr Holmes presented the various speakers of the evening.

Dr A. O. Hampton spoke on "Boeck's Sarcoid." The etiology of this condition is unknown, it may involve any tissue of the body, but the lesions in the lungs and bones are of chief interest to the roentgenologist. Where the lungs are involved,

there is a symmetrical enlargement of the lung roots with or without a diffuse parenchymal lesion. There are no pulmonary symptoms the condition is not malignant and the lesions disappear of their own accord without treatment within six to eight months. One-third of the patients have bone changes which are typically in the fingers causing fusiform swellings and present x-ray lesions varying from pinpoint destructive areas to large areas of pressure erosion. Biopsy of involved glands shows multiple tubercles without giant cells or central necrosis. Patients with erythema nodosum may present the same chest picture. In some cases sarcoid presents itself only in the pulmonary manifestations. Dr Hampton showed x-rays of several of these patients.

Dr Frank Hunter spoke on Spray Radiation in the Treatment of Polycythemia Vera and Erythroblastic Anemia. In both these conditions there is an overactivity of the bone marrow. Patients with polycythemia vera have pains in the bones enlarged spleens and dusky complexions. Two cases treated by spray radiation were discussed and blood charts shown. About 1000 r units were given over a period of two to three months in each case. All the blood elements fell and the red count stayed normal for some years. Thus far spray radiation seems to be the most successful treatment in this condition.

Erythroblastic anemia of Cooley occurs chiefly in infants and young children causing extreme pallor weakness and an enlarged liver and spleen. These patients often have Mongolian facies and may have pathological bone fractures and the blood picture presents numerous nucleated red blood cells. One such case has been treated by x-ray and the nucleated reds have fallen, while the red count has risen to a more nearly normal value.

Dr J M Robinson spoke on "The Radiographic Demonstration of Rupture of the Intervertebral Disc. This condition may occur in the cervical and dorsal region, but the condition occurs more commonly in the lumbosacral region and gives signs of a cord tumor. The soft nucleus of the intervertebral disc may rupture posteriorly or into the vertebral bodies as well as anteriorly. Two-thirds of the cases give a clinical picture of low back pain typical of sacro-iliac strain. Lantern slides were shown to demonstrate the use of lipiodol to show the rupture. In 50 per cent of these cases, there is no visible narrowing of the disc. An increase in the spinal fluid protein is a constant finding. Approximately 50 per cent give a history of trauma and 90 per cent of the group occurring in the lumbosacral region between the fourth and fifth lumbar and fifth lumbar and first sacral vertebrae. In 95 per cent of the cases the pain disappears immediately following operation.

Dr H. O. Peterson spoke on Analysis of 100 Cases of Ureteral Stones." Only those cases in which the indisputable diagnosis of this condition was made clinically were selected. Twenty-one out of the 100 cases had given no x-ray evidence but

re-examination of the plates found stones in 96 per cent of the cases. The x-ray tube should be centered so that the bones of the pelvis are not superimposed on the orifice of the ureter. Eighty per cent of all ureteral stones are found within the hoods of the pelvis and 66 per cent are located in the small area near the ureteral orifice. All the small stones are in this latter area.

Dr R. Lingley spoke on "Malignant Small Bowel Tumors. He presented four cases of this condition. Dr Lingley concludes that these malignant tumors of the small bowel may obstruct the lumen but more often dilate it and there is usually a large, soft, tissue mass palpable.

The last paper was by Dr R. H. Schatzki on "The Diagnosis of Tumors of the Colon. He pointed out several practical points in the examination of the colon. First, the patients should be prepared carefully. Secondly the most important part of the examination is a careful fluoroscopic study in which every inch is carefully observed. The rectum should be slowly filled and the enema stopped following this because the peristalsis will fill the sigmoid and part of the colon without more barium. The less barium used the clearer the outlines of the colon will be. Spot films are taken of any suspicious areas. The patient should be re-examined by fluoroscopy after evacuation of the barium.

Obstruction is the most common finding and several plates were shown to demonstrate the different kinds of obstruction. The differential diagnosis between stenosis due to diverticulitis and that due to tumor may be difficult. The diagnosis of small tumors was stressed and the typical findings in cases of polyps shown. Spasm is often present with polyps. These conditions are often only found in the post-evacuation studies.

HARVARD MEDICAL SOCIETY

The Harvard Medical Society met at the Peter Bent Brigham Hospital February 25 1936. Dr Elliott C. Cutler presiding. The medical case was presented by Dr Charles B. Kimmel. An eighteen-year-old boy a known diabetic for nine years, had been referred to the hospital for medical observation and treatment of an abscess of the left thigh. He had been seen on two previous occasions because of threatened diabetic coma, which had been precipitated on both occasions by upper respiratory infections. He had been well until six days before the present admission, when he developed a localized abscess in the left thigh at the site of a hypodermic injection of insulin. Physical examination was negative except for the abscess, which was subsequently incised and drained. He was placed on the usual diabetic régime but was given protamine insulin which decreased his insulin requirements, at 10 p.m. and 7 a.m. Dr Marshall N. Fulton remarked that this was the second case which had been given protamine insulin at the Brigham Hospital. It was admin-

istered at 5 p m and somewhat decreased the patient's tendency toward high blood sugar values in the morning. Dr Elliott C Cutler commented on the obvious immaturity of the boy and emphasized the fact that many patients with diabetes show associated endocrinological abnormalities.

Dr Richard C Durant presented the surgical case. A forty year old woman entered the Brigham Hospital on Oct 17, 1935, complaining of abdominal pain and vomiting of twenty hours' duration. Her distress had begun as nausea, and then pain had appeared in the right upper quadrant which soon became of a colicky nature. She had had a small, soft, apparently normal bowel movement after the onset of her pain. Her local physician reported that examination of her abdomen was negative, and that 15 milligrams of morphine were required to relieve her pain. Some ten hours after the onset of the pain she vomited material containing blood. The next day she entered the Brigham Hospital. Examination on entry revealed abdominal spasm and tenderness, most marked on the left side. Rectal and pelvic examinations were negative. The white count was 12,200, 92 per cent polymorphonuclear leucocytes, the red count was five million, and the hemoglobin was 85 per cent. Exploratory abdominal laparotomy was performed, and revealed a serosanguineous exudate in the peritoneal cavity, and numerous small necrotic areas scattered over the peritoneum. The bowel was hemorrhagic in appearance, and the pancreas was found to be several times its normal size. The pancreatic capsule was incised, and the abdomen was closed with drainage. She experienced a moderate amount of postoperative nausea, vomiting and pain, and had several recurrent attacks of these symptoms. A draining sinus persisted, with the discharge of approximately 300 cubic centimeters of fluid daily. On December 22, 1935 after a severe coughing spell a piece of necrotic tissue was found in the dressing. Microscopic study did not reveal the nature of this tissue, because of its poor condition, but it was assumed to be pancreatic tissue. Following the discharge of this tissue the amount of drainage steadily decreased. Her temperature, which had been persistently elevated to 101° to 102° Fahrenheit, subsided to 99°. A fluoroscopic study of the gastrointestinal tract revealed a hyperirritable stomach, with large rugae, and a five per cent residue. There were numerous shallow defects on the lesser curvature which were interpreted as representing ulcerations. The duodenum emptied satisfactorily, but was irregular in outline, due to adhesions. Dr Cutler remarked that inasmuch as a large portion of this patient's pancreas had been destroyed, it would be reasonable to expect a variation in sugar tolerance which might simulate diabetes. Although her sugar tolerance was normal shortly after her operation it subsequently became very similar to that of a diabetic patient. Dr Russell Wilder commented on the fact that, even though large portions of the pancreas were often destroyed by pancreatitis, only rarely do such cases develop diabetes. This fact illustrates

the large margin of reserve function possessed by this organ.

Dr Russell Wilder, chief of the Department of Medicine of the Mayo Foundation, delivered the address of the evening. His topic was "Spontaneous Hyperglycemia." The clinical condition designated by this term might better be known as "paroxysmal hypoglycemia", because the syndrome is characterized by periodically recurring attacks or fits. This condition was recognized clinically in 1927, when a patient was observed at the Mayo Clinic suffering from symptoms which were similar to those of insulin shock, and were immediately relieved by the administration of glucose. The blood sugar during an attack was found to be only 30 mg per cent. Operation revealed carcinoma of the pancreas with metastases. Postmortem studies demonstrated that the carcinoma was composed of cells which resembled morphologically the cells of the islands of Langerhans. Extracts of the metastases in the liver when injected into rabbits produced variations in blood sugar levels identical with those produced by insulin, confirming the belief that this metastatic tissue was functionally active. Subsequent cases which have been seen at operation have been either adenomas of the islets, or very early carcinoma without metastases. Although extracts of such tissues have been shown to have activity like insulin it cannot be said with absolute certainty that such tissue is hypersecretory. However the clinical evidence points toward this belief. Very recently a second case with metastatic involvement of the liver has been seen at the Mayo Clinic, and extracts of the metastases have given results similar to those obtained in the first case described.

Some cases of hypoglycemia have been encountered in which no islet tumor could be demonstrated, either at operation or at postmortem study. Some of these cases have been found to have abnormalities in the anterior hypophysis, e.g., a chromophobe adenoma. Cushing first described low blood sugar levels in patients with pituitary lesions. Many of these latter cases suffer symptoms from their hypoglycemia, although an occasional patient may have a persistent low blood sugar level without discomfort. It is believed that the anterior lobe of the hypophysis elaborates a hormone which is antagonistic to insulin in its action. The exact mechanism of this action is at present unknown, although it is believed by Long that the pituitary mediates its influence through the adrenal cortex.

It has been suggested that disturbed function of the adrenal cortex may be responsible for some cases of hypoglycemia. Clinical observations have not supported this hypothesis. In 150 cases of Addison's disease observed at the Mayo Clinic marked hypoglycemia was never observed.

It seems unlikely that the thyroid dysfunction is of importance in causing severe hypoglycemia, since this symptom is not observed following subtotal or total thyroidectomy.

Experimental and clinical observations have indicated that the presence of adequate hepatic func-

tion is essential for the maintenance of normal blood sugar levels. The reserve power of the liver in this respect is enormous—at least 80 per cent of the hepatic tissue must be removed in order to cause a lowering in the blood sugar. Complete removal of the liver brings about marked symptoms of hypoglycemia, which are quickly alleviated by the administration of glucose. Severe liver damage such as is encountered in advanced cirrhosis, or extreme fatty degeneration results in low blood sugar values.

Paroxysmal hypoglycemia may be precipitated in perfectly normal men by sufficiently strenuous exercise (e.g. a marathon race). Some individuals apparently are less well able to manufacture blood sugar than others and less severe exertion causes hypoglycemia in them.

Hypoglycemia has been observed to occur in newborn infants of diabetic mothers. Postmortem study has revealed very large pancreatic islets to some extent all of these infants. It is supposed that the pancreas of the fetus functions more actively than in adults in order to supply insulin for the maternal organism and that this hyperfunction continues after birth and results in a true hyperinsulinism. Frequent oral feedings with glucose immediately after birth supplemented with subcutaneous administration of 10 per cent glucose solution, have prevented the loss of infants from hypoglycemic death. Dr Wilder suggested the possibility that some of the convulsions seen in children of nondiabetic mothers within the first few days after birth might be due to unrecognized hyperglycemia, instead of the usually diagnosed birth injuries.

The treatment of hypoglycemia in adults entails the administration of glucose either orally or intravenously in the acute stages. Mild cases should be prescribed small frequent meals of the same general type as that recommended by diabetic patients in order to avoid stimulating the overproduction of insulin. Exercise should be curtailed, and the patient warned to be on his guard for early manifestations of a hypoglycemic reaction. Severe cases frequently are due to islet tumors, which occasionally are found to be malignant. Operation should be advised in all severe cases. In cases in which no tumor has been found at operation some surgeons have performed a "subtotal resection of the pancreas with good results. Recently in one such case a silk ligature was carried around the body of the pancreas and ligated anteriorly to the divisions of the cellular axis and tied snugly. The patient developed mild diabetes and previous attacks of hypoglycemia ceased.

CLINICAL MEETING OF THE FIFTH SURGICAL SERVICE AND SURGICAL RESEARCH LABORATORY OF THE BOSTON CITY HOSPITAL

A clinical meeting of the Fifth Surgical Service and Surgical Research Laboratory of the Boston City Hospital was held in the Choever Amphitheatre on March 15 1936. Dr Irving J. Walker presided. The

first paper of the evening was presented by Dr Stanley J. G. Novak, who spoke on Cross Circulation Studies in Surgical Shock. There are four main theories concerning the etiology of surgical shock, which may be briefly summarized: (1) That of Crile who believes that there is a paralysis of the vasomotor center; (2) That of Cannon who believes that as a result of trauma and tissue destruction there is liberation of some sort of toxic substance which is absorbed into the blood stream and produces shock; (3) That of Blalock, who believes that shock is produced by hemorrhage merely as a result of lowered blood volume; (4) That of Freeman who attributes the condition to overactivity of the sympathetic system. The latter worker observed the onset of shock (as indicated by lowering of blood volume) after the prolonged intravenous injection of physiological quantities of adrenalin, and after prolonged and profound hyperactivity of the sympathetic nervous system in animals showing "sham rage" (hypothalamic preparations).

Dr Novak accepted the fall in blood pressure as the criterion of shock in his animals and used the cross circulation method of Delezenne in which the hind limb of dog "B" is isolated from its body except for the nerve supply and all blood for the limb is supplied by means of cross circulation from dog "A". This isolated limb was subjected to extreme trauma, and by following the blood pressures in the two dogs by means of arterial cannulae it was determined which animal went into shock. If shock were due to absorption of toxic substances or to blood loss animal "A" would be expected to show marked drop in blood pressure while if shock were due to pain and overactivity of the sympathetic nervous system dog "B" would be expected to exhibit the lowered blood pressure. The amount of hemorrhage into the limb and total blood loss were accurately determined after the completion of the experiment by weighing the limb and by determining the amount of hemoglobin present on the sponges and instruments.

In a long series of experiments it was consistently observed that dog "B" sustained its normal blood pressure, and showed no evidence of shock, while dog "A" the "perfuser" dog went into shock with marked fall in blood pressure.

Calculations of the loss of blood to the leg and to sponges showed that there was an average loss of approximately 23 per cent of the total blood volume. It was found experimentally that a hemorrhage with the loss of 20 per cent of the blood volume was sufficient to cause shock.

By crushing the other leg of dog "B" which had previously been denervated and observing the vasomotor responses of the isolated leg it was found that dog "B" went into shock. The isolated leg showed vasoconstriction and although dog "A" showed variations in blood pressure there was no shock.

Reinfusion of the dog exhibiting shock promptly elevated the blood pressure and alleviated the symptoms of shock.

These studies of Dr Novak confirm the theory of Blaiock that "shock is hemorrhage, and hemorrhage is shock"

Dr Charles C Lund spoke on the subject "Arterial Embolism", stating that emboli in the larger arteries must arise from either the pulmonary vein, the left side of the heart, the aorta, or some portion of the artery above the site of the embolus. In extremely rare instances an embolus may pass through a patent foramen ovale, although there is little tendency for blood or emboli to pass through such an orifice, even though existent, since the blood pressures in the two sides of the heart are practically equal under normal conditions. If, however, there is an embolus to the pulmonary artery in a person with a patent foramen ovale, there is an elevation of the blood pressure in the right heart, and a second embolus may be forced through the opening into the left auricle.

In general there are two types of emboli, the first and most usual being a hard plaque of material which occludes the vessel at one point only, and the second being a soft "mushy" clot, which may fill up the whole of the artery peripheral to the occlusion. Only the first type is amenable to treatment by embolectomy.

In former years many more patients were subjected to the operation of embolectomy than at the present time. The use of the suction pump on the extremity, peripheral to the embolism, has proved successful in establishing collateral circulation in many instances. A recent report of the use of papaverine hydrochloride in patients suffering from emboli has suggested that this drug may be of value in relieving the arterial spasm which occurs following the occlusion of a vessel with an embolus.

Patients experiencing peripheral emboli are extremely poor surgical risks, and even though fifty per cent of those operated upon within twelve hours after the onset of embolism get complete restoration of circulation, many will die in the hospital of some other cause. A survey of cases subjected to surgical treatment of emboli has shown that 25 per cent leave the hospital with good circulation in the affected limb, 25 per cent leave the hospital after amputation of the limb, and 50 per cent die while in the hospital. The mortality of such patients is 90 per cent within the first two years following the embolus.

Dr Novak stated that papaverine had been used at the Peter Bent Brigham Hospital in the treatment of emboli with very discouraging results.

Dr E Everett O'Neil presented a paper on 'Gangrene and Impending Gangrene of the Extremities: Considerations and Treatment'. He emphasized the importance of careful instruction of patients with vascular disease as to the proper care of the feet. In appraising the true state of the circulation in an extremity it is important to differentiate the true occlusive type and the spastic type. The index of arterial sufficiency, the histamine test, skin thermometry before and after spinal anesthesia,

and the Landis test are all of distinct value in making this appraisal.

Application of the suction apparatus to the affected extremity is often effective in elevating the skin temperature, and alleviating pain, and may permanently aid cases with frozen feet, or arterial emboli. Dr O'Neil does not believe that cases of Buerger's disease should be so treated, however.

Cases of diabetic gangrene should be treated as surgical emergencies, and after amputation the stump should be treated with primary closure. The guillotine amputation is of distinct value in many such cases, and should be more widely used than it is at present.

'Renal Colic in the Male Caused by Vesiculitis' was discussed by Dr Augustus Riley. The anatomical location of the seminal vesicles on the posterior surface of the bladder and overlying the lower portion of the ureters is such that swelling may occlude the ureteral lumen and cause back pressure. Such occurrences have been observed in a considerable number of cases by Dr Riley, and these cases were found to have elevated temperature, abdominal spasticity, and pain fully as severe as that caused by the passage of a ureteral stone. The only method of establishing this diagnosis is by means of cystoscopy, and pyelograms. Cystoscopically a characteristic swelling and edema are observed in the trigone at the ureteral orifice, and the ureter can be catheterized for a distance of about two centimeters only. Dilatation of the ureter often will result in drainage of infected urine which may contain red blood cells. Such blockage may occasionally be the underlying factor in the production of pyelitis.

Chronic vesiculitis may cause pain localized to the inguinal regions, which is often mistakenly diagnosed as appendicitis or "gas pains".

Dr Irving J Walker and Dr W B Castle presented a case, and discussed the "Dietetic Problems Associated with Total Gastrectomy". The patient was a forty one year old male who was first seen one and one-half years previously, complaining of loss of appetite, general malaise, and weakness of three months' duration. Except for loss of appetite there were no symptoms of gastrointestinal disease. The past history was negative. X-ray studies showed a "fixed stomach" with poor peristaltic activity, and the diagnosis of gastric carcinoma or gastric ulcer with gastritis was made. The physical examination was negative, and laboratory studies, except for a low gastric acidity, were within normal limits. Dr Walker performed a total gastrectomy, making an end-to-side anastomosis between the esophagus and jejunum, and an enteroenterostomy between the jejunal loops. A Levine tube was put in place at the time of the operation, and brought into the loop of jejunum proximal to the stoma. This was left in place for four days postoperatively. The abdomen was drained under the left costal margin to remove what serum might accumulate. The patient was kept in an oxygen tent for three days after the operation, and fluids were given by hypodermoclysis.

and intravenously up to 3000 cc. daily. A soft-solid diet was given after the third day.

Gross examination of the stomach after removal showed what appeared to be an ulcer two centimeters in diameter. Microscopic studies showed a carcinoma simplex with numerous mitoses. No metastases were found. Dr. Walker believes that patients with histories and x-ray findings such as were observed in this case should be considered as having carcinoma until proved otherwise.

Dr. Castle stated that loss of weight is not to be expected in cases of carcinoma unless the disease is widespread or involves the essential organs of digestion. This patient lost thirty pounds after his operation and had weighed only 100 pounds for several months. This weight loss might be due to metastatic disease, but there was no indication of such invasion. It could not be attributed to the loss of the chemical products of the stomach. His basal metabolic rate was normal, and there was no increase in the fat in the stools. Although he showed a very great alimentary hyperglycemia and glycosuria, the loss of calories in this fashion was insignificant compared with the total caloric requirements of his body with his dietary intake. The true explanation of his failure to gain weight was finally found to be his refusal to take in adequate amounts of food. By using concentrated foods and much persuasion, he had been induced to take a 1000 caloric diet for one week, with the result that he gained three pounds. The whole problem in this case was the effort to overcome the patient's reluctance to eat.

This case was also interesting since it illustrated the fact that pernicious anemia does not occur after total gastrectomy although it is known that the stomach is of importance in preparing the anti-anemic principle. This patient did not develop pernicious anemia because of the fact that there is a store of "liver extract" in the liver sufficient to last for many months because of the fact that liver extract can be absorbed from food, and because the pyloric glands have a physiological analogue in Brunner's glands of the duodenum which act as a source for the "intrinsic factor." Because of the latter two reasons there is no reason to suppose that gastrectomy patients would develop pernicious anemia. It is true that several cases of pernicious anemia have been reported following gastrectomy but it is believed that these patients developed the disease as a result of inadequate diets and not directly because of the loss of the stomach. In true pernicious anemia there is probably a degeneration of the whole gastrointestinal tract, with many abnormalities such as poor absorption and inadequate formation of the intrinsic factor.

Dr. David D. Berlin reported on the End Results of Total Thyroidectomy for Chronic Intractable Heart Disease. He pointed out that cases subjected to this form of therapy must be very carefully selected. Surgical treatment has no place in heart disease if any benefit can be obtained from medical treatment, if the basal metabolic rate is low or if

the disease is rapidly progressing. One hundred and eighty-five cases were analyzed representing the results in twenty-six clinics. The average operative mortality in the various clinics was between five and eight per cent. Since the adoption of local anesthesia, and careful selection of cases there have been no operative deaths at the Beth Israel Hospital. A summary of the results in the two groups of cases was presented.

Results	Beth Israel Hospital	Other Clinics
A Congestive Failure		
Excellent	31%	31%
Moderate improvement	17%	32%
Slight improvement	21%	18%
No improvement	31%	18%
B Angina Pectoris		
Excellent	35%	53%
Moderate improvement	26%	33%
Slight improvement	18%	9%
No improvement	23%	5%

In summary Dr. Berlin stated that 132 of the 185 patients subjected to the operation received benefit from the procedure. He believes that it is a valuable method of treatment in properly selected cases.

ESSEX NORTH DISTRICT MEDICAL SOCIETY

The Annual Meeting of the Essex North District Medical Society will be held Wednesday May 6 1936 at the Hotel Hawthorne, Salem Mass.

PROGRAM

- 12 30—Dinner
2 00—Business meeting—Nomination of officers adoption of changed By Laws.
3 00—Fundamentals in Cancer Treatment—Grantley W. Taylor M.D. Harvard Medical School, Boston.
The Role of the Pathologist in the Diagnosis of Neoplasms—Elin Halpert, M.D., Head of the Division of Pathology The Jewish Hospital, Brooklyn
Censors meeting at the Hotel Bartlett, Haverhill
Thursday May 7 1936 at 4 00 P.M.
E. S. BAGGALL, M.D. Secretary-Treasurer

THE WACHUSETT MEDICAL IMPROVEMENT SOCIETY

Under the auspices of this Society a Medical Historical Pageant will be presented at the Rutland State Sanatorium on April 30 1936 at 8 00 P.M.

PROGRAM

The Story of Early Medicine in Massachusetts given by students of Tufts College Medical School

BOOK REVIEWS

Lobar Pneumonia and Serum Therapy With Special Reference to the Massachusetts Pneumonia Study Frederick T Lord and Roderick Heffron 91 pp New York The Commonwealth Fund \$1 00

This small handbook concerns the diagnosis and serum treatment of lobar pneumonia. A large proportion of the text is based on information gained through the Massachusetts Pneumonia Study from 1931 through 1935, which was financed by the Commonwealth Fund and carried out by the Massachusetts Department of Public Health.

Following introductory chapters dealing with the more general aspects of the problem is one concerning diagnosis and the proper selection of cases. In others, the methods of determining the type of pneumococcus and the properties of antipneumococcal serum are briefly considered. Subsequent chapters deal with the necessary precautions prior to serum administration, rules for the injection of serum and a description of serum reactions and a consideration of their treatment. Finally, the results of serum therapy are given.

The subject matter is presented simply and concisely. For those interested in more detailed information adequate references are given. Marginal notes emphasize most clearly the more important points.

Both authors are admirably qualified to write a book of this sort and it should prove of incalculable value to practicing physicians, particularly those with remote connections with the larger medical centers.

Obstetrical Practice Alfred C Beck 702 pp Baltimore The Williams & Wilkins Company \$7 00

The author's preface begins with this statement: "The purpose of this book is to present the essentials of obstetrical practice to undergraduate students and young practitioners as concisely as is consistent with the requirements of a textbook", and admirably has the author fulfilled his purpose.

There are thirty-nine chapters of text, beginning with a description of the ovarian cycle, and ending with instruction in the various standard methods of resuscitation of the newborn. Between these two is included a succinct presentation of the essential accepted facts of obstetrical practice. There is here no detailed discussion of physiological theories, but there is a clear factual recital of the whole subject. One who reads this book carefully will become acquainted with the whole range of obstetrics, he will even become familiar with the mechanics of labor and delivery which are described in enlightening detail, but he will not thereby equip himself as an expert obstetrician. The toxemias of pregnancy including hyperemesis and nephritis are discussed in fifteen pages. One page is given to pulmonary tuberculosis almost a page,

to both kinds of anemia. Heart disease is considered in little more than one page. To engross such subjects in such limited space the author has applied himself to the specific purpose of presenting to "students and young practitioners" the essentials as they are commonly accepted at present. Theories, divergent opinions and varied methods of treatment are scrupulously elided. The result is a clear didactic unit which must not be expected to serve as a complete exposition of the subject in hand.

The book is lavishly illustrated with excellent line drawings, well chosen and well placed. They illuminate the already lucid text. The paper is substantial, the print is large, the spacing is generous. A book, for the student or young practitioner, comfortable to read and profitable to study.

Lilly Research Laboratories, Dedication Indianapolis Eli Lilly & Company

No one can read the account of the dedication of the Lilly Research Laboratories in this attractive book without a thrill of joy and pride that an American Pharmaceutical concern is so progressive. The building itself, 220 feet by 53 feet, is admirably arranged and houses much of the purely research work of the Eli Lilly Staff. To go through it with out envy was more than one could expect of hard working professors and doctors who gathered there on October 11 and 12, 1934, from various medical schools in the United States.

To the opening came more than a thousand guests of whom one-fourth were beyond Indiana state lines. In this dedicatory volume one can read the welcoming address of the chairman, Mr. Eli Lilly, the remarks of Mr. J. K. Lilly, the founder, fifty years ago of the first Lilly Laboratory, upon Research in Manufacturing Pharmacy, the conceptions of Dr. Irving Langmuir, regarding the Unpredictable Results of Research, Sir Frederick Banting's Early Story of Insulin, and Sir Henry Dale's paper on Chemical Ideas in Medicine and Biology. It is fortunate that the words of these famous men have been preserved and made available to all.

At the banquet, in the evening, given the visiting scientists and clinicians, there were brief after dinner speeches by Mr. J. K. Lilly, Sir Henry Dale, Dr. Elliott P. Joslin, Dr. George R. Minot, Dr. Frank R. Lilly, Dr. George H. Whipple, Dr. Carl Volgtlin, and the Director of the Laboratories, Professor George H. A. Clowes. The volume also contains informal talks upon special problems of research which were given on the following day, together with a general description of the Lilly Research Laboratories.

Our congratulations, Eli Lilly Company, for the forward step you have taken to help humanity and the medical profession, and especially for the high ethical standards which now as always have characterized the endeavors of your organization.

METASTATIC ABSCESS OF THE PROSTATE*

BY C. J. E. KICKHAM, M.D.† AND NORMAN A. WELCH, M.D.‡

ABSCESS of the prostate gland is generally regarded as a direct or indirect complication of Neisserian infection, either in its acute or chronic process. Frequently, as a result a prompt diagnosis is not made and the proper therapeutic measures are unnecessarily delayed. There is no basis for this attitude, as such abscesses are not infrequently encountered where there is no history of venereal infection and where its absence is substantiated by the clinical findings. Prostatic suppuration may occur as a sequela to some acute systemic infections such as influenza and typhoid fever. Burbee reported four cases which followed influenza during the epidemic of 1918. Abscess in the prostate gland may be frequently precipitated by urethral trauma following instrumentation. Kemble recently reported a case complicating diabetes mellitus and septicemia. A similar case has come under our observation. There is also the group in which the prostatic infection is metastatic in origin and in which the primary focus can be demonstrated. The most common foci are superficial pyogenic infections such as boils, carbuncles, felon, and paronychia. Stromayer reported four instances of fatal carbuncle with metastatic abscesses in the prostate gland. Randall, Kretschmer, Ball, and Herman and Carp have described cases of metastatic prostatic abscesses from demonstrable distant foci. The bacteriological cultures from the prostates in these patients showed *Staphylococcus aureus*. The usual history is that of a healthy individual with a recent pyogenic infection and with symptoms out of proportion to the local pathology who suddenly develops bladder difficulty in the form of frequency and painful micturition which progresses rapidly to a complete retention.

Patch and Reid, in 1932 reported a case of prostatic abscess, metastatic in origin complicated by bilateral renal carbuncles. Cases have been described in which perinephritic suppura-

tion followed prostatic abscess of pyogenic origin. However, in a recent review of sixty-six cases of carbuncle of the kidney, including a personal report, Graves and Parkins found only one instance (Patch and Reid) in which the renal condition was preceded by prostatic suppuration. von Lichtenberg refers to the association of renal and prostatic abscesses. He attributes this to a special etiological factor connecting the two organs but he does not specifically state what this mysterious factor is. He does say, however, that in a pyemic condition the obstruction offered by a swollen prostate would easily tend to lower the resistance of the kidneys and thus render their hematogenous infection all the easier.

Our interest in the subject was stimulated by the following case.

The patient, Carney Hospital No. 34297, a Canadian American married male of twenty-nine years was admitted on January 3, 1934, with a history of diurnal and nocturnal urinary frequency and pain on voiding of eight days duration which was climaxed by complete retention two days before admission. Five weeks previously he had developed a boil on the dorsum of the left wrist which was incised by his local physician. He denied venereal disease by name and symptom. The past genito-urinary history was negative.

The family history was negative. The patient was married and had two children. His past history was unimportant. He had always been in good health and the systems were essentially negative.

Physical examination found a well-developed and nourished man. The color was good and the tongue moist. The heart and lungs were normal. Blood pressure was 118/72. On examination of the abdomen the kidneys could not be felt and were not tender. There was definite resistance to palpation tenderness and dullness over the suprapubic area. The external genitals were negative. Rectal examination found a normal sphincter. The prostate gland was somewhat enlarged and boggy throughout. The right lobe felt a little elevated and more prominent than the left, but was not fluctuant.

Laboratory findings. The urine was cloudy alkaline specific gravity 1.013 albumin trace sugar none sediment pus, free and in clumps. The white blood count was 32,000.

Clinical course. There had been no elevation of temperature, but the history and clinical findings suggested a prostatic abscess. He was placed on a program of alternating hot rectal irrigations and hot sitz baths, high fluid intake and urinary antiseptics. He was placed on catheter drainage. After

*Read at the Meeting of the New England Branch of the American Urological Association at Boston, February 7, 1935.
†From the Urological Service, Carney Hospital, South Boston, Mass.
‡Kickham, C. J. E.—Assistant Urologist, Carney Hospital, Welles, Norman A.—Visiting Physician, Carney Hospital. For records and address of authors see "This Week's Issue" page 119.

being on this régime for six days with no apparent improvement, the rectal findings indicated the presence of definite suppuration in the right lateral lobe. On January 9 a perineal incision and drainage was carried out and approximately two drams of pus were liberated from the right lobe of the gland. The report of the culture was "Staphylococcus aureus." There was a postoperative elevation of temperature, but his convalescence was otherwise uneventful. He was discharged from the hospital January 19 at which time he was voiding without discomfort although some frequency persisted.

Interval history About three weeks following discharge the patient developed acute pain in the right flank which had been preceded by several days' premonitory flank discomfort. This was accompanied by marked vomiting and neck pain. Abdominal examination revealed marked spasm and tenderness over the right renal area. The temperature varied from 100 to 103 degrees. He was definitely toxic. Readmission to the hospital was advised. Digital examination of the rectum found no evidence of recurrent abscess formation.

Readmission (February 15, 1934) Cystoscopy. No obstruction was encountered in the urethra. The bladder tone, tolerance, and capacity were normal. The mucosa was moderately injected. The left ureteral orifice appeared normal. The right orifice was quite red in appearance. Number 4 ureteral catheters were passed along the ureters 28 cm and no obstruction encountered. There was a slow intermittent drip. Specimens were obtained from both kidneys for culture and sediment examination.

Laboratory findings The bladder urine showed many pus cells. The right kidney urine showed eight to ten red blood cells and an occasional white blood cell, and the left kidney two to six red blood cells per high power field. The kidney cultures were negative. The phenolsulphonphthalein divided function test showed the appearance of the dye from both sides in three and one half minutes and 2 cc, 625 per cent on right, and 4 cc 12 per cent on left, after ten minutes. The blood urea nitrogen was 13 mg per 100 cc of blood. The Wassermann was negative. Blood culture was negative.

Days Plain kidney ureter bladder with the catheters in position delineated the left renal shadow normal. The right side was somewhat obscured but did not appear definitely abnormal. No shadows were present which were consistent with calculi. The left ureteropyelogram was normal. The right pyelogram revealed the upper and middle calyces normal but the lower calyx was slightly elongated and there was a definite small filling defect delineated.

Clinical course The patient's general and local condition did not improve. He experienced a great deal of pain in the right renal area, over which region he was quite tender and spastic. At this time the right kidney was definitely enlarged, especially at the lower pole where a palpable excruciatingly tender mass could be outlined. His temperature varied from 100 to 102.6 degrees and his pulse rate was 100 to 120. The white blood count remained elevated. It was felt that we were dealing with a carbuncle of the lower pole of the kidney, although the possibility of a solitary renal abscess or infarct was kept in mind. On March 18, the patient was taken to the operating room and preparations carried out for an exploration of the right kidney. Spinal anesthesia was administered following which his blood pressure climbed from 122 to 226 and the pulse rose to above 140. His general condition was very poor and he was returned to his room. Following this, his renal pain and tenderness subsided and the palpable mass could not be felt. His temperature gradually subsided also. Any further at-

tempt at surgery did not seem to be indicated. Slight tenderness over the lower pole of the right kidney still persisted, however. The report of the urine sediment on the day he was taken to the operating room showed "many pus cells." There was no change until four days later when the report was "a large number of pus cells, free and in clumps." Several days before his discharge, he developed severe pain over the left renal area, but this persisted for only a few days. He left the hospital on March 27, 1934. Following discharge, the patient's general condition gradually improved, although his temperature was elevated to 99 to 100 degrees for over a month. He was placed on a program of general supportive treatment consisting of a high caloric diet, increased fluid intake and ultraviolet lamp therapy in conjunction with regular office treatment. The smear of the prostate showed a few pus cells when last seen and the voided urine still had a few white blood cells present. He was symptom free and apparently in excellent health.

COMMENT

Since we were dealing with a patient who had a recent superficial pyogenic infection, and since we had no reason to suspect the presence of Neisserian disease, it was felt that a diagnosis of prostatic abscess, metastatic in origin, was consistent with the clinical and laboratory findings. Relative to the nature of the kidney pathology, a tentative diagnosis of renal carbuncle was justified although solitary abscess and infarct were not excluded in the differential. The physical findings and general clinical picture did not suggest perirenal suppuration. Microscopic and cultural studies of the urine from the affected kidney disclosed no evidence of infection. The delineating of a filling defect in the lower calyx of the right renal pelvis by retrograde pyelogram, suggested pressure from an intrarenal mass. The history of staphylococcal infection, both superficial and in the prostate gland, the clinical course and local physical findings correlated with the laboratory and roentgenological studies seemed to confirm this diagnosis. Cardiac pathology, the most common factor in the development of renal infarcts, was not present so far as we could determine clinically, although there was a rapid pulse rate for several weeks. Barney and Mintz state that acute or chronic heart disease, especially of the valvular type, is almost always present when renal infarcts are encountered.

The spontaneous regression of the renal pathology was quite remarkable. However, in reference to carbuncle of the kidney, Lazarus states that the process may point toward the pelvis and extend into it, rupture spontaneously, and drain itself with ultimate healing and cure. He adds, however, that this is unusual. It is not uncommon to encounter perirenal suppuration due to direct extension from a renal focus, such as renal carbuncle or solitary abscess, to the perinephrium. It is likewise logical to expect in some cases direct extension and rupture into the renal pelvis. The reaction to

the spinal anesthesia in this instance was quite unusual. The definite change in the clinical picture immediately thereafter as revealed by the disappearance of the renal mass and the symptomatic improvement of the patient was probably a coincidence. The manipulation and attendant trauma in placing the patient in the right lateral position may have been a precipitating factor in the rupture of the carbuncle into the renal pelvis however, although this is quite conjectural.

SUMMARY

A case of metastatic abscess of the prostate with secondary renal suppuration rupturing spontaneously into the kidney pelvis is reported. The importance of staphylococcal infection as primary foci for abscesses of the prostate and kidneys is emphasized. Urinary difficulty and retention in a patient with a history of recent

superficial pyogenic infection should suggest metastatic abscess of the prostate gland.

A WARNING ABOUT ACIDIFICATION THERAPY IN CASES OF
RENAL INFECTION DUE TO THE PROTEUS BACILLUS*

BY RICHARD CHUTE, MD†

RECENTLY acidification therapy in the treatment of urinary tract infections and calculi has been advocated so widely and enthusiastically, and without warning that it could do harm that I am impelled to point out one condition in which I feel that the indiscriminate use of acid therapy may lead to trouble. This condition is renal infection with the proteus bacillus. This bacillus is a not uncommon invader of the urinary tract and produces an infection which is extremely persistent and stubborn, and is very resistant to the ordinary methods of combating urinary infections. It has the property of rapidly splitting the urea of the urine and producing ammonium thus making the urine intensely alkaline. This alkaline infected urine greatly predisposes to the formation of calcareous incrustations and stones in the urinary tract which are a characteristic finding in these cases.¹ These stones and incrustations are composed chiefly of calcium phosphate. Phosphates, as you know, tend to precipitate out in an alkaline urine, and will not precipitate out of a strongly acid urine. In accordance with this property of phosphates systemic acidifying therapy is used in patients who form calcium phosphate stones in order to keep the urine strongly acid and thus prevent any tendency of the phosphates to precipitate out with the possibility of a tendency to stone formation.

With these facts in mind let me tell you about

a certain patient of mine a man of thirty-one who had one stone removed from his right kidney in 1929 and another removed from his left kidney in 1933. Both these stones were composed chiefly of calcium phosphate. In 1933 he was studied thoroughly from the metabolic standpoint and in view of a slightly raised blood calcium and a slightly increased amount of calcium excreted in his urine it was thought that he might possibly be suffering from hyperparathyroidism and his neck was explored, but no parathyroid tumor was found although one parathyroid gland was never located. Last fall (1935) he entered the hospital again and I found that he had a proteus bacillus infection of each kidney and that a stone in the right kidney which I had been watching grow gradually for more than two years had become large enough to require surgical removal. This I did leaving in a nephrostomy tube for irrigations of acid. Then I decided on a drastic and forceful campaign to stamp out this infection. Since he was rather washed out following the operation and since the ketogenic diet has not been remarkably successful in treating proteus infections I did not start him on this diet, but decided to acidify his urine strongly and give large doses of methenamine. Accordingly I started with the usual dose of one gram of ammonium chloride four times a day and the urine remaining alkaline, gradually increased the dose over a period of about five weeks reaching a peak at the end of this period when by means of a modification of Keyser's acidifying syrup² I gave as much as twenty grams of ammonium chloride per day for three days. Still the urine did not become acid. At this point Dr. Fuller Albright pointed out that ammonium compounds are nitrogenous and are excreted in the urine as urea.

Years ago Folin showed that an increase in the nitrogen of the diet is followed by an increase in the amount of urea excreted in the urine. Therefore, in this case by the ingestion of large amounts of ammonium chloride, the amount of urea excreted

*From the Massachusetts General Hospital.
†Chute, Richard—Assistant Urologist, Massachusetts General Hospital. For record and address of author see "This Week's Issue" page 158.

in the urine must have been greatly increased, which superabundance of urea had doubtless been giving the proteus bacilli a very rich pasturage and promoting their growth and their output of ammonia. Then I switched to nitrohydrochloric acid and gave that for another month, at one time giving as much as 60 cc of Crances nitrohydrochloric acid mixture² in twenty four hours. I had only slightly better luck with the nitrohydrochloric acid and, even with the maximum dose, never succeeded in getting the urine more than very slightly acid (never below pH 6.5). During these two months of intensive acid medication the patient passed at least four unilateral stones, each one about the size of a drop of water, which were composed chiefly of calcium phosphate. Near the end of the two months, the patient began to complain of pain in the unoperated kidney, and you can well imagine my feelings when x-rays showed that a good sized stone had formed in the kidney pelvis (figs 1 and 2). Plates taken

smaller dose than I had given, that person will excrete, via his urine, more than six times as much calcium and more than one and a half times as much phosphorus as he ordinarily would.

Then I saw the explanation. By giving a large amount of acidifying medicines I had strongly acidified the system and caused a great increase in the amount of calcium and phosphorus excreted via the urine, a condition analogous to hyperparathyroidism. This would probably have been all right if I had succeeded in getting and keeping the urine strongly acid, thus absolutely preventing the precipitation of phosphates. However, due to the rapid ammonia production by the proteus bacilli, I was never able to get the urine really acid, and so there existed the unfortunate combination of a greatly increased amount of calcium and phosphorus in a urine which was alkaline and infected with proteus bacilli—a combination strongly predisposing to stone formation.*

X-ray on December 17 1935 showed one small stone in left kidney

FIG 1

X-ray on January 24 1936 showed the same small stone and in addition a large stone in the kidney pelvis which had formed since the last x-rays—thirty eight days before.

FIG 2

thirty eight days before had not shown this, so that the stone must have formed pretty much during that period of about a month between pictures. The other kidney on which I had operated and which was getting daily lavage with acetic acid through the nephrostomy tube, showed no new stone formation. Shortly after this, the patient had his fourth kidney operation and I removed this stone. It was soft and crushed easily and was obviously a new formation not yet fully calcified. It was composed chiefly of calcium phosphates, but also showed some oxalate and a little carbonate.

On thinking this case over and wondering why the patient had this sudden increase of stone formation—one large stone and at least four small ones in less than two months—and had formed stones infinitely faster than he ever had before, I remembered that acidifying the system greatly increases the excretion via the urine, of both calcium and phosphorus. This has been pointed out by Hunter³ of London, and Aub and his co-workers⁴ in this country. This latter group showed that when a person's system is acidified by taking four to six grams of ammonium chloride per day, a

SUMMARY

The three points which I wish to make are the following:

1. The urine in infections of the urinary tract should always be cultured in order to know what organism one is dealing with, since what may be the proper régime in treating infections

*Since the above paper was written Dr. Edward L. Pearson, Jr. of Salem has reminded me of the importance of the functional efficiency of the kidney in the matter of urinary acidification. The better the renal function the more effect the acid medication will have in the direction of acidifying the urine and the less effect it will have in the direction of producing systemic acidosis and increased excretion of calcium and phosphorus. On the other hand in the presence of poor renal function there is a greater tendency toward systemic acidosis and thus probably toward increased calcium excretion with at the same time a lessened ability of the kidneys to excrete a strongly acid urine.

In the case reported above I do not believe this matter played an important part, as the nonprotein nitrogen of the blood was not elevated and the renal function as measured by the excretion of phenolsulphonphthalein by each kidney was pretty good. No estimations of the CO₂ combining power of the blood were made. However I believe that this is an important consideration and I plan to carry on further investigations along this line with complete biochemical studies.

due to the colon bacillus may be the wrong thing in dealing with infections due to the proteus bacillus

2 In cases of infection with the proteus bacillus, ammonium chloride would seem to be unsuitable as a urinary acidifier for biochemical and bacteriological reasons.

3 In treating infections of the kidneys with the proteus bacillus, systemic acidification may be dangerous and lead to the formation of new stones, unless one is successful in obtaining a strongly acid urine. This may be impossible

due to the rapid manufacture of ammonia by the proteus bacilli

THE TREATMENT OF HYOSPADIAS
IN THEORY AND PRACTICE*

BY H. H. CABOT, M.D.†

I DO not propose this evening before this society of experts to discuss in detail the well established methods of dealing with the deformities of hypospadias. Rather I propose to draw upon my own experience in the attempt to point out some of the difficulties and hopefully to suggest some methods of avoiding them.

The requirements of successful correction of the deformities of hypospadias are twofold: first the correction of the almost always present deformity of curvature, and secondly the construction of a satisfactory urethral canal.

CORRECTION OF THE DEFORMITY OF CURVATURE

It has, I think, been too widely assumed that the correction of the deformity of curvature may properly be regarded as a step or stage in the procedure of correcting the deficiency of the urethra. This has led but too often to the attempt to correct the deformity after the child has reached the age of eight or ten or even adult life. Thus no opportunity is allowed for development of the parts after the correction has been satisfactorily done. Although the desirability of correcting the deformity in very early life has been frequently stressed by various writers on the subject, it has not, I think, been sufficiently grasped by the people who are most likely to see these patients, namely the obstetricians, the pediatricians, and the general practitioners. I therefore risk stating again the opinion that the correction of the deformity should be undertaken in very early life probably at or before the age of two years. A considerable interval amounting to at least three or four years should then be allowed to elapse before the construction of the urethra is undertaken.

Methods of overcoming the deformity of curvature

Read before the meeting of the New England Branch of the American Urological Association at Boston, Massachusetts, February 7, 1926.

*Cabot, Hugh—Consulting Surgeon, Mayo Clinic. For record and address of author see "This Week's Issue," page 649.

ture.—For this there are three types of procedure which are perhaps applicable to more or less definite types of deformity. For the average deformity seen in the cases of penile and penoscrotal hypospadias the method by transverse incision on the ventral aspect is as a rule satisfactory. It is commonly held that in the more severe deformities two such incisions should be made, one near the base of the glans and one just in front of the opening of the urethra. This method I have used in a considerable number of cases but have come to the opinion that one incision is as a rule sufficient. The crux of the matter lies in the very complete removal of the fibrous tissue occupying the position of the missing part of the corpus spongiosum.

One would gather from the literature that the transverse incisions are often carried only through Buck's fascia, and deeply through the abnormally thick fibrous septum lying between the corpora cavernosa. This does not seem to me satisfactory and I believe that the very complete removal of the fibrous tissue, chiefly in the midline through a transverse incision placed about the midway between the meatus and the glans, is more satisfactory. Success will as a rule depend upon the completeness with which the fibrous tissue is removed together with a fairly free mobilization of the skin flaps on either side, so that they may be readily approximated vertically and without tension. In some cases the satisfactory bringing together of the lateral ends of the incision will bring tension upon the skin of the penis to an undesirable extent. This can be readily overcome by a longitudinal dorsal incision which relaxes the skin so that approximation on the ventral surface becomes easy and the dorsal incision can be closed transversely a position which it will occupy of its own accord.

The next method is that involving the use of pedicle flaps, and it is most likely to be required in the extreme deformities generally associated with the perineal types of hypospadias.

Blair has devised a very clever method of utilizing the prepuce to cover the raw surface on the ventral side necessarily created by the removal of the confining fibrous tissue and the straightening of the penis. I have myself most frequently used the method of Edmunds, which consists in the creation of a buttonhole flap in the prepuce which some weeks later when the blood supply has become satisfactorily adjusted is utilized after division in the center to close the gap (fig 1). By the use of these flap

FIG. 1. Buttonhole flap of Edmunds two months after the first operation.

methods the deformity can be considerably overcorrected, which in these extreme cases is, I believe, desirable.

It should be pointed out that the flap methods which utilize the prepuce will veto the possibility of using one of the methods for formation of the urethra, namely, that of Ombiédanne. It is essential, therefore, that a decision be made at this time whether the Ombredanne operation is to be utilized and, if such is the case, correction by other methods than the use of flaps from the prepuce will be essential.

The third method is that suggested by Hagner who utilizes skin grafts passed above the confining fibrous tissue at two points. These grafts are sutured about a trocar, which is then passed through the penis transversely above the fibrous bands. This of course means that they must invade the cavernous tissue of the corpora cavernosa. After an appropriate interval these tunnels are divided on the ventral surface, thus overcoming the deformity. Hagner reports very favorable results by this method. With it I have no personal experience and tend to think that it is more likely to be useful in the patients at or approaching adult life than for the children at the more appropriate age. I should also be fearful that the placing of these

grafts through portions of the cavernous tissue would result in the formation of scar which might itself as time went on reproduce the deformity.

THE CONSTRUCTION OF THE URETHRA

Here we have at our disposal and in more or less common use three types of procedure. These stated in order of their historical precedence are the Thiersch-Duplay type, the Bucknall type, and the Ombiédanne type. I do not propose to discuss in detail or to illustrate these operations, since they have been fully illustrated in articles by Cecil, Lyle, and Cabot, Walters, and Counsellor.

The Thiersch-Duplay type — The principle here involved is the use of flaps with very broad pedicles taken from the shaft of the penis, and in the case of the perineal type of deformity from the non-hair-bearing skin in the cleft of the divided scrotum. The operation is applicable to any type of deformity. It is, I think, essential to recognize the principle introduced by Thiersch of turning the skin flap which is to form the urethra from one side, and the flap which is to form the outside covering from the other, thus avoiding as far as possible the superimposition of suture lines.

The next point which I wish to stress is the importance of broad union of the edges of the flaps rather than the attempt to suture edge to edge as is appropriate for the average surgical incision. It seems desirable to invert the flaps forming the urethral tube in such a way that the edges are turned inward and the surfaces applied to each other by sutures which do not emerge on the skin margin. For the purposes of this suture I believe the use of very fine catgut, articulated to a fine curved needle so that there is no excessive bruising of the tissues, as is involved where the ordinary eye needle is employed, is desirable.

Diversion of the urine during the period of healing is essential. This may be done either by suprapubic cystostomy or by the creation of a perineal boutonnière. Cecil, who has had a large experience, strongly advocates the use of the suprapubic method. In my hands this has not worked notably more satisfactorily than has the perineal method. In either case should the catheter become obstructed or displaced, urine will pass along the new formed urethra. Particularly in children, suprapubic drainage does not seem to me secure against failure of drainage, and in fact has in my hands been less satisfactory. The perineal boutonnière can be easily made after the plastic operation has been carried out on the urethra, over an indwelling catheter. This will be facilitated if a suture upon a curved needle is passed deeply about the urethra after the patient has been placed in the lithotomy position. Tension on this suture draws the

urethra up against the skin, and a very small opening can then be made directly into the urethra through which the catheter can be readily withdrawn and properly adjusted. Young advises the placing of a suture about the urethra in front of the boutonniere, tied sufficiently tightly to close the canal and thus avoid urinary contamination. I have not felt willing to do this since the risk of constricting the urethra to such an extent as to form a stricture does not seem to me one which can be safely overlooked.

In passing it may be noted that the accurate adjustment of the catheter should be made only after the patient has been replaced on the table with the legs extended normally. If adjustment is made while the patient is still in the lithotomy position, it will almost always be faulty, commonly because the catheter will lie too far out as the result of change of the tension of the perineal tissues. In keeping the catheter draining constantly, the addition of a constant suction by means of the principle of the Bensen pump has seemed to me very helpful. Certainly the liability to blocking of the catheter and passage of urine about the catheter is very importantly diminished and generally avoided.

The aftercare of these cases is one of considerable importance, and there is, I think, no very general agreement as to the best method. There is much to be said for the very early removal of dressings, thus allowing the parts to be exposed and kept under electric lights. This requires very careful supervision by the nurse and will in practice require twenty-four hour supervision in order to avoid accidents. In some cases, at least, my experience has shown that there is liability to edema coming on during the first few days, and I have therefore compromised by using a dressing for three or four days, at the end of which time lights are substituted. The original dressing should be a moist one—we have generally used acriflavine—placed in such a way as to keep the penis in full extension and exert moderate, even pressure. This moist dressing will dry during the first twenty-four hours and form a very effective splint.

Where all goes well and particularly in the hands of surgeons who have had considerable practice, this operation gives, I think, the most perfect result of any of the methods (fig. 2). On the other hand, it must be freely admitted that the liability to fistula formation is a serious handicap. Although the principle of avoiding overlapping flaps is undoubtedly important, it will be found in practice that these flaps tend to contract in such a way as to bring the suture lines particularly at the penoscrotal angle very closely into line. The occurrence of a fistula is most common at the penoscrotal angle and in my experience has been difficult to repair in some cases requiring two or three attempts. I tend to think that this is due to the increased tension which occurs in the lateral flap at this

point, and I particularly call attention to the desirability of mobilizing the flaps very freely, avoiding tension of even the most moderate amount and if necessary releasing the tension on the flaps by a dorsal incision at the base of the penis. Complete success with this operation requires experience, scrupulous care in the placing of sutures and patience during the operative procedure. Skillful aftercare is undoubtedly more important in the success of

FIG. 2. End result of the Bucknall operation shortly after closure of a small fistula at the penoscrotal angle.

this operation than in the case of the other two types.

The Bucknall operation.—As you know, the principle here involved is the use of the skin of the scrotum in the formation of the lower wall of the urethral canal. In his original communication in 1907 Bucknall suggested that the operation had two limitations. He thought that it could not be applied to cases of perineal hypospadias and he suggested that since the skin from the scrotum was hair-bearing, this might give rise to complications after the patient reached puberty. His first objection, namely, that the operation is not applicable to cases of perineal hypospadias, is not valid. It is very easy to convert the perineal type of hypospadias into the penoscrotal type. In these cases where there is always a cleft scrotum the skin which will be utilized in the formation of the urethra is non-hair-bearing. The inner tube having been formed from this non-hair-bearing skin, the dissection should then be carried deeply in to the scrotum on either side and the cleft deformity entirely obliterated. I have found it useful to bring the loose connective tissue on either side of the scrotum together over the newly formed tube of the urethra and then to approximate the skin of the scrotum so that the parts are restored to a practically normal rela-

tionship At this stage in the operation perineal diaphragm should be employed An interval of some months should then be allowed to elapse before the typical procedure of Bucknall is carried out on the urethra which now emerges at the penoscrotal angle

Bucknall's second objection, that the hair-bearing skin may introduce a later complication, is a valid one Vermooten reported to this Association in 1930 a case previously operated upon by Churchman in which the growth of hair in the urethra had caused serious compli-

Bucknall method may avoid what appears to me to be the only serious objection to this operation

In my earlier cases I thought it would be safe to leave out the quilled suture which was advised by Bucknall Experience, however, satisfied me that the use of the quilled suture in approximating the lateral flaps was highly desirable For this purpose I now use a heavy aluminum wire which seems to me more satisfactory than any other method of quilling the suture

As to the place of the operation it may be

FIG 3 Modified Bucknall operation It will be noted that the skin utilized in the formation of the inner urethral tube is from a non hair bearing region In other respects the operation follows closely the procedure of Bucknall

cations I have myself seen two cases in which this complication had arisen and I shrewdly suspect that it is more common than we have been led to suppose from a perusal of the literature This complication led me to abandon the Bucknall operation after ten years of quite successful use More recently I have carried out a procedure suggested by Cecil of using only non-hair-bearing skin for the formation of the inner tube (fig 3) Thus I have had an opportunity of doing in two cases, with successful immediate results Since the end-result will not be complicated by the development of hair, it seems possible that this modification of the

safely said that it avoids the danger of fistula formation with great certainty The immediate result is unsightly as compared with the Thiersch Duplay operation, but if it is done at the appropriate age, growth of the parts overcomes the redundant tissue and the functional results are sound As originally described, the operation left an unduly large meatus This can be satisfactorily corrected at a later stage, preferably one year after the original procedure, and is, I think, a desirable addition to technique

The Ombriédanne operation—This is a highly ingenious method which has been utilized by its author in an amazingly large series of cases

The principle is to utilize a scrotal flap to form the urethra up to a point near the base of the glans. The balance of the urethra is then formed from the buttonholed prepucial which, although at first giving a wide funnel shaped meatus can be reconstructed by later steps in the operation to give a most satisfactory canal. The operation is not technically difficult and does not require the niceties of technique of the Thiersch procedure. Occasionally the portion of the canal formed from the prepucial may be lost as the result of sloughing but this is on the whole an uncommon accident. The only valid objection that I can see is the use of the hair bearing tissue of the scrotum for the formation of a considerable part of the canal. This is the same objection which has proved a stumbling block in the Bucknall operation as originally devised. It is true that there is no evidence from the literature that this is an important complication. On the other hand there is perhaps no field in urologic surgery in which we know so little in regard to what may be called the end result. As a rule these patients are or should be operated upon in childhood. An end result cannot be estimated until these patients have grown to full maturity and the final evidence in regard to the complete correction of the deformity and the complete utility of the urethral canal can be satisfactorily judged. I have been unable to find any considerable collection of such end results and can only hope that as time goes on we shall get more evidence upon this point.

In summing up, it seems to me quite clear that the surgeon who desires to offer to these little patients the most satisfactory outcome must be equipped to utilize each of these various procedures where it seems most appropriate. For the skilled plastic surgeon the Thiersch operation has many advantages. For the occasional operator it is likely to prove difficult. The Bucknall and Ombredanne procedures are less difficult and are likely to prove more satisfactory in the long run. In certain cases both operations may be employed as for instance where some surgeon has light heartedly done a circumcision thus removing essential tissue. Also the Bucknall type of operation may be used in those probably rare cases in which the preputial flap of the Ombredanne operation has sloughed to a greater or less degree. Again the Bucknall operation can be utilized where previous operations of the Thiersch type have failed and where there is excessive scar tissue in the region from which the lateral flaps of the Thiersch operation would have to be taken. Time alone will allow a decision as to the importance of the growth of hair as a complication of the Ombredanne operation.

In a recent paper by Walters he reports his results in thirty two patients subjected to the

Ombredanne procedure. In these the results were excellent in twenty-eight. In four, more or less sloughing of the preputial portion of the canal required the use of the Bucknall procedure to finish the job. This is a most satisfactory showing and is the largest group of cases of this operation reported in this country. He also reports on sixteen cases where the Bucknall type of operation had been employed. Of these, excellent results were obtained in fourteen, while in two on account of injury to the skin flap in the second stage of the Bucknall procedure, small fistulae developed, which, however, were readily corrected. I have myself utilized the Thiersch method in thirteen cases. They have required forty six operations which means of course that particularly in the early cases I was not able to avoid fistula formation. The end results, however, after these many procedures have been eminently satisfactory.

DISCUSSION

DR. GEORGE G. SMITH: I must admit that I have approached the few cases of hypospadias that I have seen in the last few years with a great deal of trepidation. I have had a good deal of grief. The earlier ones I tried to get away with by making a perineal boutonnière but I didn't find it worked so well. Within the last few months I have done two cases in boys of five to six years in whom I did suprapubic cystostomies with practically primary union in both cases. One of these has left the hospital. I saw him several months later and he has a fistula of about the size of a hair through which a few drops of urine leak at the original site. I suppose some time I shall probably have to do something to that. I will remember what Dr. Cabot said about the closure of it. The other case is still in the hospital. We just took his tube out today and I think he has a small fistula. There is a suspicious looking little hole there but in the main it looks very satisfactory. I think that in any I do after this I shall do a suprapubic cystostomy at the time.

There is one point that I think is very essential to bear in mind. That is that either the patient or the patient's family shall understand what your plan

is I remember one Italian boy on whom I did a fist stage at the Baker. He was a rather wild patient while he was there. We didn't speak the same language and about a week after he got out he came around to the office and I thought he was going to commit mayhem. He said "Before the operation, the hole is down at the end, now look where it is."

I have enjoyed this talk of Dr Cabot's very much, as I always enjoy everything he says. I think he has covered a great many of the practical difficulties which have not been covered in any of the talks I have heard before. I have seen pictures of the finished results, but haven't heard of any of the hot spots on the way and I appreciate very much Dr Cabot's going over these hot spots so thoroughly.

DR J DELLINGER BARNEY I also approach a hypospadias in fear and trembling. I will omit the subject of fistula because it has been talked of before. As a father must stand up for his own child, I would like to say that I think the perineal drainage is rather better than the suprapubic, perhaps because of the fact that I haven't had the difficulty that Dr Cabot spoke of in finding the urethra. This is due entirely, of course, to the fact that I have done it by the method of making a perineal boutonniere which I described some time ago. I think the urethra is pretty easily found by this method and I think it will work in these penoscrotal cases perfectly well, but I must confess I have not used it in one of the perineal type. The catheter is pushed into the bladder entirely and the outer end of the catheter grasped by a clamp. The clamp bearing the catheter is carried on through the urethra into the deep bulb and then pushed against the skin so that one simply cuts then on the protruding end of the clamp. The clamp with the catheter grasped in it comes out through the incision which is about 1 cm in length. That can be done with the patient in the dorsal position without the necessity of putting him up in lithotomy position. I don't say that perineal drainage is better than suprapubic but it has been more satisfactory in my hands. Also it is advantageous because it can be done with equal ease for several times in the same patient and without untoward results.

DR E GRANVILLE CRABTREE I have enjoyed Dr Cabot's exposition for the same reason that Dr Smith has already mentioned. These cases do have some grief connected with them. The question of whiskers in the urethra is a very definite one with the Bucknall operation. I had a family that had but three children, they were all males and they all had penoscrotal hypospadias. I did exactly the same operation on the three of them. The last one was done nine years ago. The first one has a regular paint brush effect which seems not to bother him, he won't let any one pull the hairs out. The other two were the same type of operation and have had no difficulty whatever with hair production. They were all done quite young.

DR DEMING I have noticed that Dr Cabot in his talk, has not mentioned the fact of bringing the urethra up through the glans and most of the slides, which he has exhibited, show the opening of the meatus in the frenum area. Is it necessary to split the glans penis and carry the urethra to its normal position?

I was very glad to hear Dr Cabot stress the post operative care of these cases. I have failed in some cases because I did not do the dressings myself and now when I operate on a hypospadias case I am in every day and I do the dressing myself. I dare not leave it to anyone on my staff and I find, by doing that, I can accomplish much and make every operative step a success instead of a failure. I am delighted to hear Dr Cabot stress this point with a good deal of emphasis.

As regards the cause of hypospadias, Dr Cabot made a statement that he thought it probably was due to the devil. I was wondering what he thought of Dr Young's explanation with respect to derangement of the genes.

I wish to express my appreciation to Dr Cabot for the clear and direct presentation of the subject.

DR HUGH CABOT I hope that if Doctor Smith should ever return to the use of perineal drainage, he will try constant suction. I had no luck until I tried it and since trying it, I have had no leakage. I did not succeed in keeping the patients dry with suprapubic drainage. Cecil advises that the suprapubic should be done two weeks before the other operation. I dislike making any more bites than I have to.

Doctor Barney, did you not have difficulty in getting a small enough clamp to go through these urethras with the catheter? I did not use that method because I did not have a clamp small enough to pass. I was afraid of traumatizing the urethra. You do it, I take it, before you begin your operation. You cannot do it afterwards.

DR J DELLINGER BARNEY Yes, it is a preliminary step. I have the catheter come out through a little hole in the perineum. With a small No 10 or 12 catheter and a mosquito snap, I haven't had any trouble.

DR HUGH CABOT My first patient who grew hair apparently had only urethral irritation and as he had a very capacious urethra, an endoscope could easily slip in and you could see the whiskers. The next patient I saw came in on account of a fistula with a lot of local irritation. There was no stone formation in that case around the hair, but there was the beginning of a hair ball. The last one I saw differed only in that he had six fistulae. The canal was almost all fistulae and there was a lot of local irritation which, if it goes on long enough, will lead to stone formation on the hairs.

Doctor Deming asked about the meatus. It seems generally agreed that the balanitic type of hypospadias is best treated by masterly neglect, because the results of our attempts to overcome balanitic hypospadias have been very unsatisfactory. I am satisfied if I can get a normalized meatus placed about in the position of the balanitic type of deformity. Certain it is that the minute you invade tissue of the glans with its erectile tissue and very thin covering, you take on a lot of extra trouble and bleeding. One patient who finally discouraged me was an adult who almost bled to death on two occasions where we had cut the glans. He had transfusion twice. When the smoke cleared away it had all sloughed and we were back where we started. I quit after that.

LYMPHOBLASTOMA (HODGKIN'S AND SARCOMA
TYPE) OF BONE*With a Report of Three Cases Simulating Primary Malignant
Tumor of Bone

BY JACK SPENCER, M.D.† AND RICHARD DRESSER, M.D.†

LYMPHOBLASTOMA is a primary disease of the lymphatic system usually manifesting itself clinically by enlargement of peripheral mediastinal, or abdominal lymph nodes. It should be appreciated, however, that this disease may invade any structure of the body. Numerous reports appear in the literature of involvement of the gastrointestinal tract, the central nervous system, and the genito-urinary tract.

The demonstration of bone lesions is becoming increasingly more frequent. Burnam (1926), in a review of 173 cases found only two with osseous changes (1.1 per cent). In the same year one of us (Dresser) collected ninety-five cases of lymphoblastoma at the Massachusetts General Hospital, only four of which showed bone involvement (4.4 per cent). These four cases all presented large sternal tumors which were clinically obvious. During the next five year period an additional 149 cases were studied in which particular attention had been paid to the demonstration by roentgen examination of osseous changes. In this series sixteen cases with bone involvement were discovered, an incidence of 10.7 per cent. Uehlinger (1933) reported fifty cases of Hodgkin's disease, forty-eight with postmortem examination of which seventeen (34 per cent), showed osseous changes. These changes were not all demonstrated antemortem. In a series of 172 cases reviewed by Craver and Copeland (1934) twenty-seven (15.7 per cent) presented bone involvement.

The distribution of bone lesions in order of frequency is as follows: spine, pelvis, sternum, ribs, skull, and extremities. The roentgen picture is usually that of a purely destructive process, less often a combination of bone destruction with hyperplasia and rarely an osteoplastic change without destruction (Hultén). A diagnosis based on roentgen findings alone will usually be that of malignancy either primary or metastatic, rarely osteomyelitis.

Bone infiltration generally occurs in the advanced stage of the disease after the diagnosis of lymphoblastoma has been established. The osseous changes then present no great diagnostic problem. Occasionally, however, bone is involved early in the course of the disease when

there is little or no demonstrable enlargement of the lymph nodes. The correct diagnosis can then be made only by the removal of a specimen for pathological examination. The following is a brief summary of such a case reported in an earlier communication. A man of thirty-four came under observation at the Massachusetts General Hospital presenting a large tumor mass in the posterior parietal region. About six months previously a barber had called the patient's attention to a lump on his head. Physical examination was negative except for the scalp tumor and several very small glands in the cervical region which were thought to be of no significance. Roentgen examination of the skull showed a large defect in the parietal bone. The possibility of a primary new growth was considered, and a biopsy was done which was reported as lymphoblastoma.

This case was included in the publication in 1931 of a series of twenty cases with lymphomatous involvement of bone. Since then we have collected an additional series of forty-one cases. Of the latter group three presented single lesions in the bones of the extremities which gave rise to the predominating symptoms, and which were erroneously diagnosed primary bone tumor by clinical and roentgen examination.

CASE 1. A white female aged twenty-four when first seen gave a history of increasing pain and swelling of the left knee of two years duration beginning about the time of termination of a full-term pregnancy. Physical examination showed a hard fixed mass involving the lower end of the left femur. There was no glandular enlargement, and the spleen and liver were not palpable. Laboratory studies showed 9,000 white blood corpuscles with 73 per cent polymorphonuclears, and 80 per cent hemoglobin. A roentgenogram showed a destructive process involving the lower third of the femur with a break in the cortex and periosteal thickening of the shaft. (Figure 1 n h.) A diagnosis of primary bone tumor was made, most probably Ewing's. Amputation was done and the pathological report was lymphoblastoma sarcoma type. One year following amputation the patient developed a five centimeter gland in the corresponding groin which responded to a moderate dose of high voltage roentgen rays.

CASE 2. A white female aged thirty-nine gave a history of swelling in the left antecubital region of ten weeks duration. Examination showed a hard fixed swelling of the lower third of the left humerus. There was no enlargement of the lymph glands and the spleen was not felt. The liver edge was just palpable. Laboratory studies showed 3,550,000 red blood corpuscles, 19,650 white blood corpuscles, hemoglobin 55 per cent. Roentgen examination showed a soft tissue mass in the lower third of the

arm with areas of rarefaction of the lower third of the humerus. The roentgen diagnosis was primary bone tumor. Operation exposed a soft friable mass infiltrating the lower third of the arm and apparently involving the joint. The lower third of the shaft was completely denuded of periosteum. Biop-

FIGURE 1a. Case 1. Irregular destructive process at the lower end of the femur with a break in the cortex and periosteal thickening.

FIGURE 1b. Case 1. A central tumor with necrosis extending through the cortex. The periosteal thickening is well seen.

sy from the humerus was reported as 'lymphoblastoma'. Infection followed the operation making amputation of the arm necessary. The patient later developed pain in the right shoulder, and roentgen examination demonstrated osseous changes in the head of the humerus. The patient gradually failed and died a year later.

CASE 3 A white male, aged forty, on first admission gave a history of stiffness and pain in the back of the neck of one year's duration. During the past two months there had been progressive weakness in the right arm and sensory changes in the left hand. The patient was thought to have a spinal cord tumor and lipiodol injection showed a partial block at the level of the second dorsal vertebra. The spleen and liver were not enlarged and there were no palpable glands. Laboratory studies showed 3,910,000 red blood corpuscles, 9,200 white blood corpuscles, 83 per cent hemoglobin, 69 per cent polymorphonuclears, 30 per cent lymphocytes, 1 per cent mononuclears, no eosinophils. Hinton test negative, spinal fluid Wassermann positive once and when repeated at a later date negative. Laminectomy was performed and a specimen of tissue removed for study was reported as "fibrosis and chronic inflammation". The course was uneventful until the patient was seen again six months later with a history of glandular enlargement in the right side of the neck and intermittent pain in the left leg associated with twitching of the muscles of the thigh. The glands in the neck had receded spontaneously. The pain became very severe and incapacitated him for three or four days. There were no genito-urinary or gastrointestinal symptoms. Examination showed a few enlarged glands in the right side of the neck which were thought to be of no significance. A mass was found over the anterolateral aspect of the upper third of the left femur. A roentgenogram of the left femur revealed irregular patches of diminished density about the greater trochanter with thickening of the periosteum extending down to the middle of the shaft. Biopsy was done and reported as "scirrhous lymphoblastoma". This patient was given high voltage roentgen ray treatment to the bone lesion. Following radiation there was temporary decrease in the size of the mass and relief of pain. The abdominal nodes, however, became involved and the patient failed rapidly. Death occurred eight months after the discovery of the bone tumor.

DISCUSSION

Lymphoblastoma is found to infiltrate the bone marrow in a large percentage of cases which come to autopsy. One may expect to demonstrate bone lesions antemortem by roentgen examination in ten to fifteen per cent of cases. According to Uehlinger, who has reviewed a large series of autopsied cases, there is no such thing as a purely primary lymphoblastoma of the bone. There is invariably lymph gland involvement, although it cannot always be demonstrated clinically. Extension to the bone occurs in two ways: first, direct invasion from adjacent diseased nodes, secondly, a metastatic dissemination presumably via the blood stream. Osseous changes usually occur late in the course of the disease after the diagnosis has been established. Attention has been called to four cases, one previously reported, in which the bone involvement gave rise to the presenting symptoms and in which an erroneous diagnosis of primary bone tumor was made.

In case 1 the evidence was so strongly in favor of primary bone tumor that amputation of the thigh was done. In case 2, the correct diagnosis was made only by biopsy of the bone lesion of the humerus. Infection later followed, making amputation of the arm necessary. Case

It at first presented a clinical and roentgen picture of a spinal cord tumor. A pathological diagnosis of arachnoiditis was made following laminectomy and removal of a specimen. The patient later developed enlargement of the cervical glands which regressed spontaneously and were not thought to be of clinical significance. Finally a lesion in the left femur was discovered which was thought to be a malignant bone tumor. The correct diagnosis of lymphoblastoma was made by biopsy from the lesion in the femur.

Since lymphoblastoma is always a generalized disease, amputation of an involved extremity is contraindicated as a curative measure. Irradiation may be expected from irradiation in such cases, but the bone lesions do not respond as well as the glandular lesions.

It should be emphasized that, in the differential diagnosis of a bone lesion presenting an atypical roentgen picture, the possibility of lymphoblastoma should be considered even though there is no demonstrable enlargement of the lymph nodes.

TWO UNUSUAL TRANSFUSION REACTIONS

BY PAUL A. YOUNGE, M.D.*

IN 1931 Bordley of the University of Pennsylvania reviewed the literature on transfusion reactions and collected seventeen cases characterized by urinary suppression, uremia, jaundice and a high mortality. No cause for the reactions could be determined in most of the cases he reviewed.

In the past three years about 100 blood transfusions have been performed at the Free Hospital for Women and two typical 'transfusion reactions' both of which were definitely explained, have been observed.

The purpose of this report is to emphasize the mistakes which led to these nearly fatal accidents and to add the case histories to the literature upon this subject.

The first accident happened as the result of using a very dangerous technique of matching blood which was taught in one of the Boston hospitals. This faulty technique consists of placing a drop of the patient's serum on a glass slide, adding a drop of a saline suspension of the donor's cells and dropping a cover slip upon the mixture. If the two drops are large there is enough space between the slide and cover slip for the red blood cells to move about freely. On the other hand, if very small drops are used the liquid spreads out in a very thin film and the red blood cells are fixed between the two glass surfaces. In this particular case the 'cross matching' was observed for one-half hour and checked by another intern. Immediately after the transfusion accident the matching was repeated by the same technique using the original serum and suspension of cells. Again there was no sign of agglutination in an hour but with the hanging drop technique agglutina-

tion occurred within five minutes. Fortunately some of the patient's blood which was removed before the transfusion had been saved and she was found to be a Group IV (Moss). The donor was a Group II.

Eight months later another typical transfusion reaction occurred. Both the patient and the selected donor had been grouped and doubly cross-matched, i.e. the patient's cells in the donor's serum and the donor's cells in the patient's serum. Needless to say both the grouping and the cross matching were done by the hanging drop method. The patient and the donor were in Group II (Moss) and no agglutination occurred in either of the 'cross-match' tests within half an hour. However immediately after the transfusion accident all the tests were carefully repeated, with the finding that the donor's cells began to hemolyze in the patient's serum after forty minutes and were completely hemolyzed within sixty minutes.

In the first case citrated blood was pumped into the vein under pressure taking about five minutes to introduce 300 cubic centimeters. The symptoms commenced in less than a minute after the transfusion was completed, or in about six minutes after the start. In the second case whole blood by the new B.D. grooved syringe method was introduced at the rate of about 15 cc per minute, i.e. three strokes of the syringe per minute. Symptoms developed after 90 cc of blood had been given—about six minutes after the start.

Both patients were transfused again a few days after the accidents and no symptoms of any type were observed.

No similar case could be found in the literature comparable to the second accident, i.e. a

Younge, Paul A.—Assistant Pathologist and Surgeon to Out-Patients, Free Hospital for Women, Brookline. For record and address of author see "This Week's Issue," page 319.

transfusion reaction due to hemolysis of the donor's cells which occurred in vitro forty minutes after they were placed in the recipient's serum. Therefore it must be concluded, as the tests were repeated three times, that in this particular instance the reaction was due to the hemolysis of the donor's red blood cells in the patient's blood stream.

CASE REPORTS

CASE 1 This first case is the one to whom blood of the wrong group was given. She had a severe reaction, but made a remarkable recovery following decapsulation of the remaining kidney. She was a thirty-three year old mother of four children, who entered the hospital May 29, 1933, complaining of a draining sinus in a left kidney scar of two years' duration, and pain in the left flank, a nonproductive cough, frequent chills, fever, and rapid loss of strength and weight of three weeks' duration.

Five years before admission she began to have urinary frequency and painful micturition, both of which gradually became worse until two years before admission, when she developed, in addition, pain in the left flank, chills and fever, a pleuritic pain in the left side of the chest and a nonproductive cough. The bladder was extremely irritable. An operation was done at that time, presumably drainage of a perinephric abscess or a nephrostomy. The bladder symptoms cleared up entirely but she was extremely sick for many months and the wound continued to discharge pus up to her admission to this hospital. There was a family history of tuberculosis and the patient had been definitely exposed.

She was the typical picture of chronic sepsis, emaciated, pale and dehydrated, with herpetic lesions on her lips. Her lungs and heart were normal by physical examination and x-ray. In the left upper quadrant there was a tender rounded mass about three times the size of a normal kidney, which was continuous with an indurated area beneath a scar in the left flank. There was a small sinus in the posterior part of the scar discharging thick, yellow pus.

Laboratory data: hemoglobin 55 per cent; Taillqvist, leukocyte count 9000, polymorphonuclears 90 per cent; the urine had a VST of albumin, a specific gravity of 1.020 and 10 white blood cells per high power field in a centrifuged catheter specimen. An intravenous phenolsulphonphthalein test showed good renal function with 55 per cent excretion the first hour and 10 per cent the second. Intravenous pyelogram disclosed a normal but slightly enlarged kidney on the right with good function and an enlarged kidney on the left with no function. Her temperature swung from 99.6° to 105.6° F.

The clinical diagnosis was a perinephric abscess on the left, secondary to a tuberculous kidney.

On June 3, 1933, the left kidney was removed and a perinephric abscess drained under spinal anesthesia. The kidney showed tuberculosis microscopically. Two days after the operation, because of continued fever, anemia and a dropping white blood count which was then 6000, a transfusion of 300 cc of blood was given by the citrate method. Within a minute of its conclusion she complained of sudden abdominal distress and a sensation of distention. Almost immediately she complained that she was suffocating; her face became flushed and then rapidly markedly cyanotic; she was gasping for breath. Oxygen, adrenalin and caffeine relieved her somewhat and within several hours she

was quite comfortable. At no time did she complain of lumbar pain.

The next morning her skin and sclerae were deeply jaundiced. She had not voided since just before the transfusion. Two ounces of black urine with a heavy sediment were obtained by catheterization. She had no complaints but her mental faculties were dulled and she was disoriented at times.

During the first five days following the accident she was given intravenously from 2000 to 3000 cc of 2½ to 10 per cent glucose in normal saline daily. At one time she received 300 cc of 10 per cent saline intravenously and another time 50 cc of 50 per cent glucose. Her urinary output varied from 50 to 100 cc daily. The urine was muddy brown, contained bile and had a specific gravity of 1.010 to 1.013. There was a ST of albumin constantly. At first it was loaded with red cells but they disappeared and gradually it became loaded with white blood cells. The urine at no time contained sugar, in spite of the fact that she received intravenous glucose daily.

On the third day she had a mild convulsion which lasted about fifteen minutes. She gradually developed generalized edema, which by the fifth day was so marked that her eyes were shut and the labia minora were so tense that they appeared to be on the verge of bursting. She was practically comatose.

The essential pathologic process in the kidneys following a transfusion reaction apparently is necrosis of the epithelium of the tubules plugging of the collecting tubules with coagulated protein and blood pigments and marked edema. In the hope that a better circulation of blood through the remaining kidney could be obtained the capsule of the right kidney was stripped back on the fifth day. This was done under paravertebral nerve block. The capsule was extremely tense. The kidney cortex was a pale, grayish chocolate color. As it was very friable, it was injured in several places for a depth of two to three millimeters. As far as could be determined, there was no possibility of injury to the kidney pelvis or ureter during the operation.

Within twenty-four hours after the decapsulation a profuse watery discharge began to drain from the wound. The volume increased daily for the first seven days, when it amounted to 3100 cc, after which it decreased and finally stopped entirely on the eleventh day. The patient's condition was noticeably improved forty-eight hours after the decapsulation.

Nine days after the transfusion and four days after the decapsulation she was normal mentally and the edema had entirely disappeared clinically. The urine output, i.e., from the bladder, had begun to increase for the past two days and at this time (four days after decapsulation) amounted to 200 cc in twenty-four hours, making a total of 1065 cc during the nine-day interval since the transfusion. On this day she was given 500 cc of citrated blood without any ill effects and the urine output steadily increased.

She was discharged from the hospital forty-one days after admission with both wounds practically healed. Since then, for two and a half years, she has been carefully followed and has remained in excellent health. The nonprotein nitrogen content of the blood did not return to normal until three months after discharge. Since that time her kidney function and blood chemistry have been well within normal limits.

During the acute stages of the urinary suppression the nonprotein nitrogen content of the blood reached a level of 255 mg per 100 cc of blood nine days after the reaction and then gradually receded.

to 70 mg. per cent on the day of discharge. The dye excretion test with phenolsulphophthalein intravenously was 85 per cent in two hours on admission 0 per cent for at least twelve days after the transfusion—none could be demonstrated in the drainage fluid 12 per cent in two hours seventeen days after the transfusion 27 per cent on the day of discharge and 57 per cent three months after discharge, when her nonprotein nitrogen had returned to normal also. The blood pressure remained between 110-120/80 all during the illness.

By far the most interesting feature of this case was the fact that during the first eleven days following the decapsulation 12100 cc. of fluid were collected from the wound. What amount actually drained was impossible to determine accurately, because much was lost. During this same interval 1800 cc. of urine was collected from the bladder. It was speculated at the time that the drainage fluid might possibly be a mixture of glomerular filtrate and urine from the collecting tubules escaping through the traumatized cortex, or serum and edema fluid from the wound. However this could not be definitely determined as specimens of drainage fluid and urine collected during the same intervals were practically identical except in NaCl content.* From the analyses it appeared that both fluids had gone through the same process. The drainage fluid was much lighter in color and upon standing developed a small pellicle. Otherwise no distinguishing point could be made out. It is regrettable that a biopsy was not done on the kidney at the time of decapsulation.

CASE 2. The second case is the patient who serum hemolyzed the donor's red blood cells. She was a forty-five year old mother of six children admitted February 18 1934 complaining of malarial rigors of three months' duration. Pelvic examination was essentially negative. Her hemoglobin was 45 per cent Talqvist, red blood count 3,250,000 and the blood smear showed normal platelets marked achromia, anisocytosis and polikilocytosis and the average size of the red blood cells was smaller than normal. A transfusion was decided upon before

operation. The patient and her husband were grouped and cross-matched. They were both in Group II (Moss) and their bloods directly compatible.

The transfusion was done by the direct method using the new B-D grooved syringe. After the patient received 90 cc. she became short of breath and complained of severe pain in the back. She became cyanotic and her skin was cold and clammy. The pulse and blood pressure remained unchanged. Two hours later her temperature was 102.6 her breathing was easier and the cyanosis less marked.

For the first forty-eight hours she had an intake of 7000 cc. and voided only 300 cc. she was jaundiced and developed pitting edema over the thighs. On the second day her nonprotein nitrogen was 61 mg per cent and the uric acid was 7 mg per cent. The urine at first contained a large trace of albumin a few red blood cells and cellular casts. The specific gravity was fixed at 1.009. After three days the urinary output began to increase the jaundice and edema gradually disappeared and she was transfused again on the fourth day with no reaction. The albumin gradually disappeared from the urine and at discharge twenty days following the transfusion, her blood chemistry was normal. There was no albumin or casts in the urine and the phenolsulphophthalein test showed 80 per cent excretion in two hours. She was followed for two months and her urine remained normal. Five days before discharge a dilatation and curettage and application of radium were done for functional flowing.

From our experience with these cases we strongly recommend the use of the hanging drop technique in matching blood and feel that it is very dangerous to say a donor is suitable to use unless the blood matching tests are observed for at least forty-five minutes to an hour.

PUBLIC HEALTH

Operating on a budget of \$2,200,000 for public health activities The Rockefeller Foundation in 1934 engaged in field research on yellow fever malaria hookworm disease, tuberculosis malarial fever yaws, and diphtheria conducted yellow fever surveys and control campaigns carried out projects in malaria control supported numerous demonstrations of complete public health programs gave aid to the organization or maintenance of essential services of state and national health departments and continued its contribution for the training of public health personnel through aid to schools and institutions of hygiene and public health as well as by support of a fellowship program.

As a general result of technical methods developed in the laboratory it has become evident that

there are two endemic areas of yellow fever in the world. The boundaries of these areas have been approximately established. One of them occurs in Africa and extends from Senegal in West Africa to the upper reaches of the Nile. The other occurs in South America, and occupies practically the whole of the Amazon Valley reaching for short distances into other watersheds.

It has come to be recognized that yellow fever may exist not only in a mild and almost unrecognizable form but also in forms not associated with its recognized carrier the *Aedes aegypti* mosquito. The disease is transmitted and perpetuated in certain endemic areas by vectors different from the single one (*Aedes aegypti* mosquito) encountered in Havana Panama and epidemic cities in general.—*Information Service of The Rockefeller Foundation*

CASE 22181

PRESENTATION OF CASE

A fifty-three year old white American carpenter was admitted complaining of pain in the left foot.

Twenty years before entry the patient had frostbite of both legs. Following this he noted that when exposed to cold his feet were usually more prone to discomfort than his hands. One and a half years prior to admission he noted that his left foot became much colder than his right during the winter. For about three years he had some soreness in the arch of his left foot after walking. This was relieved only by rest. After two years, similar discomfort initiated by walking occurred in the region of the left ankle. Three months later he began to develop cramps in his left calf after walking about 300 yards and this progressed to the point where he was unable to walk more than 100 yards without resting. During this time he also noticed that the skin of his left foot was much cooler than the right. Two weeks before entering the hospital a reddened area appeared between the left fourth and fifth toes. This region became ulcerated, acutely painful and there was some swelling of the foot. A small tender lump appeared in the left groin shortly afterward.

The patient smoked about one package of cigarettes daily. Up to three years ago he had smoked a pipe incessantly.

Five years before admission he sustained a head injury. Since that time he had dizzy sensations when reclining on his left side and the vision in his left eye was markedly impaired.

Physical examination showed a well-developed and nourished man in no discomfort. The left pupil was slightly larger than the right and did not react to light or distance. The heart and lungs were negative. The blood pressure was 145/88. The left lobe of the prostate was slightly enlarged, irregular, rather firm, but not tender. The left foot was cool and pale except for a faint bluish area measuring 2 by 5 centimeters which extended back from the dorsum of the fourth and fifth toes. Between the two toes was an ulcerated crack which was markedly tender. Dorsalis pedis and posterior

tibial pulsations were not felt and the popliteal was quite weak on this side. On the right side the dorsalis pedis was present but the posterior tibial was weak. Upon elevating the left foot it blanched in one minute and when lowered a flush appeared only after two minutes. There was a scaly, silvery skin lesion on the dorsum of both hands over areas measuring 2 by 4 centimeters each.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. The hemoglobin was 90 per cent. A blood sugar was 111 milligrams per cent.

X-ray examination of the left foot showed no evidence of variation from the normal. The right leg and foot showed no evidence of calcification of the vessels. There was a small bony projection from the lateral and anterior surface of the middle shaft of the right tibia which was interpreted as an osteochondroma.

On the second hospital day a low left thigh amputation was performed.

DIFFERENTIAL DIAGNOSIS

DR. LELAND S. MCKITTRICK: Three years ago this fifty-three year old American carpenter began to have pain in the arch of his left foot after walking. He was unrelieved by arch supports, the pain was then felt in the ankle, and later in the calf of the leg, always after effort, and always relieved by rest. An ulceration then appeared between the toes. He was admitted to this hospital. The examination showed the absence of a palpable pulsation in the vessels to the foot and a diminished pulsation in the popliteal artery. His foot blanched on elevation and there was more or less rubor when it was dependent. There was nothing in the history or physical examination to suggest involvement of the vessels to any of the other extremities.

This is a characteristic picture of a man with progressive obliterative arterial disease. This, to my mind, limits the differential diagnosis to a very few lesions, namely, thromboangitis obliterans, arteriosclerotic gangrene, and diabetic gangrene. The latter is, for practical purposes, excluded by the absence of sugar in the urine and a blood sugar of 111 milligrams per 100 cubic centimeters. It would seem to me that the diagnosis rests between early gangrene, due to thromboangitis obliterans or that due to an arteriosclerotic obliteration.

Thromboangitis obliterans may occur in any race. It is almost entirely limited to men. The age of onset of symptoms is usually under forty, occasionally between forty and forty-five, and only rarely fifty or over. We do occasionally see it, however, in men beyond fifty. The symptoms are usually of long duration, more frequently over three years than under. The disease usually starts in one extremity, frequently

involves a second and occasionally all four X rays are usually negative for any evidence of calcification of the arteries. Only rarely does the disease show such definite progression as in this case. Thus has been one of definite progression from onset to admission to the hospital ending with amputation through the lower third of the thigh. This procedure is rarely necessary in thromboangitis obliterans in fact only about 3 per cent of the cases in this hospital have had amputation done at this level. The great majority of cases left the hospital either without amputation of any kind or with the loss of one or more toes. Failing the latter a Gritti Stokes amputation is usually done. In most instances there is evidence of involvement of at least one other extremity before so much involvement of one.

The average of patients with arteriosclerotic gangrene is sixty five years. On the other hand we do see a group of patients in the sixth decade who have gangrene secondary to an arteriosclerotic process. The duration of symptoms may be as long as three years but is usually under two years, and frequently under one. The disease in many instances runs a progressive course, ending in amputation through the lower third of the thigh and in only a small percentage of cases is amputation of a digit successful. X ray usually shows evidence of calcification but there is the occasional case where the x ray is negative.

From the above resume of the two diseases it is obvious that it is impossible for me to make a definite diagnosis in this particular case. This man is older than the usual patient we see with thromboangitis obliterans. His story is somewhat shorter than we usually find, and his disease is distinctly more progressive than in many instances. On the other hand, there is nothing either in the history or physical findings not entirely consistent with the occasional patient whom we see with thromboangitis obliterans. As for arteriosclerosis, he is well below the usual age at which this disease is found, but on the other hand, he is not too young. Although calcification of the vessels can usually be demonstrated by x ray, its absence in this case does not exclude arteriosclerosis. However, because of the fact that this man's symptoms began at the age of fifty because they have been definitely progressive from the beginning with intermittent claudication then early gangrene, admission to the hospital and amputation through the lower third of the thigh, without evidence of involvement of any of his other extremities I favor the diagnosis of arteriosclerosis.

Dr. HENRY H. FAXON. There is one point that may be worth making although it really paraphrases what Dr. McKimtrick has already said. Namely the diagnosis in this case preoperatively was of more than pedantic interest

because in the cases of Buerger's disease we are often free to go ahead with a local procedure on the foot even when the dorsalis pedis artery cannot be felt. Whereas in the arteriosclerotic group, with absence of peripheral pulsations if we do any surgery we are usually forced to do a radical operation.

The rest of the case has been covered with only one addition, namely the infection between the toes in all probability gained entry through a fissure in the skin caused by epidermophytosis which is so often the case.

Dr. SOMA WEISS. I would like to bring out one point. This patient is reported to have suffered from frostbite twenty years ago. Gruber and other German authors have pointed out the interesting fact that the histologic picture of the vessels in frostbite is exactly or almost exactly identical with thromboangitis obliterans. You find the same intimal changes and the same cellular reaction described in thromboangitis. I should like to ask Dr. McKimtrick if there is any study in the literature on which one could estimate the ultimate results of frostbite. It is perfectly possible that frostbite is not an indifferent episode in predisposing the patient to vascular complications.

Dr. MCKIMTRICK. I do not know. I have not seen any but I have not covered the literature with that in mind. It is quite possible it may be there, but I saw no reference to it.

PREOPERATIVE DIAGNOSIS

Thromboangitis obliterans left leg

Dr. LELAND S. MCKIMTRICK'S DIAGNOSIS

Arteriosclerotic gangrene

PATHOLOGIC DIAGNOSIS

Thromboangitis obliterans

PATHOLOGIC DISCUSSION

Dr. TRACY B. MALLOY. A great deal of the confusion in this group of cases rests at the pathologists' door in that we are not reliable enough in our own differential diagnoses, even after amputation has been performed and we have had a chance to study the vessels to give the clinicians the help that they need. There is a considerable group of cases in about this age group the late forties and early fifties, where I find it almost impossible to decide whether we are dealing with thromboangitis obliterans or not. Those cases often show very significant amounts of arteriosclerosis and the histologic picture of Buerger's disease is not to my mind sufficiently diagnostic so that I am unable to recognize it with certainty if arteriosclerosis is also there. This case, however, happens to be one in which we were not presented with that difficulty. There is no evidence of

arteriosclerosis whatever, and the findings are entirely consistent with uncomplicated thromboangitis

This is the posterior tibial artery with an elastic tissue stain. You can see the internal elastic lamina which is practically unreduplicated. The lumen of the vessel is completely filled by an old organized thrombus and that thrombus contains a large number of canalizing vessels. The media shows no trace of calcification. We have perhaps thirty sections from various vessels in this leg and neither atheroma nor medial calcification could be demonstrated in any of them. That lesion on the screen is perfectly characteristic of a healed stage of Buerger's disease.

I have selected another vessel for comparison. This is the anterior tibial artery and again you see the lumen filled with thrombus, one rather large and numerous small canalizing vessels, and, moreover, what also is very characteristic of Buerger's disease, involvement of the venae comites. The veins show fibrous thickening of the intima and the adventitia of all the vessels is distinctly thicker than normal, matting them all together. In order to find any acute disease we have to go higher up in the vascular tree. This is the upper end of the popliteal artery, filled with fresh thrombus, much of which, however, has dropped out of the section, but along the upper margin you can see it is being actively organized and one canalizing vessel has already developed. In one respect the case differs from the average in that the media of the vessel shows an unusually marked inflammatory infiltration. Large numbers of new blood vessels are penetrating it and they are surrounded by lymphocytes and particularly by monocytes in considerable numbers. We really have a panarteritis here, not merely an endarterial process.

The relationship to frostbite is always an interesting one to discuss and is well illustrated by this case. A very large proportion of cases of Buerger's disease do give a history of frostbite and a good many people, particularly the Germans, suggest an etiologic relationship. It has in general always seemed to me more reasonable that the patients get their frostbite because they already have an impaired circulation from Buerger's disease. In a case of this sort, however, where the frostbite occurred twenty years before his vascular symptoms showed any sign of progression, such a theory seems improbable. The case could certainly be cited as evidence for the converse point of view which has recently received support from the experimental work of Leriche and Fontaine*. They believe that a local thrombotic process can reflexly provoke extensive vascular spasm and even secondary arteritides in distant vessels.

DR FELIX DEUTSCH During the war in Austria we had a great deal of experience with just this sequence of events. I am inclined to believe that people who develop frostbite are fundamentally endowed with very unusual vascular systems to start with.

DR MALLORY That is possible.

CASE 22182

PRESENTATION OF CASE

A seventy-five year old American machine shopworker was admitted complaining of lower abdominal pain.

For about one year before entry the patient had had occasional abdominal distention. During this time he had transient attacks of nausea lasting for only a fraction of a minute and there was also increasing constipation although no details were noted. About three and a half weeks before entry he began to have a gnawing angry pain just below the umbilicus which radiated to the right flank and into the left subcostal region. The pain was persistent and relieved only by medication prescribed by a local physician. At about the same time the constipation became more pronounced and he resorted to cathartics. As a result his stools became loose and watery. Several were questionably tarry in appearance. The appetite was poor and there was no nausea. On the day before entry the patient vomited once and once again just before coming to the hospital. There had been a weight loss of about twelve pounds during the current illness.

For several years the patient had occasional sharp pain radiating across the chest which his physician had called acute indigestion. Nine years before entry a doctor had told him he had diabetes, but he had never had any treatment. Forty-two years ago he was operated upon for empyema and sixteen years later for an umbilical hernia.

Physical examination showed a well-developed and nourished elderly man. The lungs were clear and the heart was normal. The blood pressure was 150/90. The peripheral arteries were thickened. The abdomen was soft and there was slight tenderness in the epigastrium. Peristalsis was active. A rectal examination showed tarry stools.

The temperature, pulse, and respirations were normal.

Examination of the urine showed a specific gravity of 1.020. There was a trace of albumin and a green precipitate with Benedict's reagent. No diacetic acid was found. The sediment contained many white blood cells, some of which were clumped. The blood showed a red cell count of 4,200,000, with a hemoglobin of 80 per cent. The white cell count was 5,000. A phe-

*Leriche R and Fontaine R. Presse Med 43: 1953 (Dec 4) 1915

nolsulphonephthalein test showed 20 per cent excretion of dye in two hours. A nonprotein nitrogen of the blood was 67 milligrams. Gastric contents were coffee colored and gave a one plus reaction to the guaiac test. Free acid was 60 units and the total acid 90.

An x-ray examination showed a large stomach, high in position, which filled without evidence of defect. No barium could be forced through the pylorus. Deep stomach peristalsis was visible and after half an hour a small amount of barium had trickled through the pylorus. There was a 15 centimeter area of ulceration about one centimeter beyond the completely filled portion of the stomach. The duodenum was incompletely filled.

Constant gastric drainage and intravenous glucose infusions were instituted with marked improvement in the patient's symptoms. On the fifth hospital day an abdominal operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. WALLACE: The gnawing pain in the region of the umbilicus in a younger person should certainly suggest something in a Meckel's diverticulum. In a man over seventy I think it is extremely unlikely that he would have lived to that ripe old age without having some trouble before that from a Meckel's diverticulum. Gnawing pain in that region suggests most strongly a lesion in the region of the pylorus or duodenum.

His pain apparently had no relation to meals and was not relieved by food or alkalies.

The stools were questionably tarry in appearance. We have a suggestion of bleeding in the upper gastrointestinal tract. We have no suggestion in the history of cramp-like or intermittent pain to suggest obstruction either in the small or large bowel. There has been a weight loss of about twelve pounds during the current illness. I believe that means loss of appetite and inadequate intake of food.

We might wonder with pain in the region of the umbilicus if he might have some recurrence of his hernia, but I believe that is extremely unlikely after sixteen years, and the type of pain is not suggestive of anything we might blame on a hernia.

The abdomen was soft and there was slight tenderness in the epigastrium. Again we have indication of trouble in the region of the stomach.

"A rectal examination showed tarry stools." This presents more evidence of bleeding in the upper gastrointestinal tract.

We have some evidence of concentrated urine. There is no mention of any urinary symptoms. The rectal examination does not mention any abnormality of the prostate. A man of seventy-five might well have some urinary infection

which probably has nothing to do with his chief complaint.

We have reason to believe that there is some gastrointestinal bleeding. There is evidence of very little anemia. Perhaps that is not a true picture in the light of the possible dehydration.

There is evidence of some impairment in the function of his kidneys. I believe it is quite likely that dehydration plays a considerable part in the high nonprotein nitrogen.

"Free acid was 60 units and the total acid was 90." I interpret that as being rather high normal for the stomach.

DR. AUBREY O. HAMPTON: This patient was apparently examined in the horizontal position. No films or fluoroscopy were made in the usual upright position. The stomach is unusually high. It runs across transversely. Here is the diaphragm. It is the type of stomach with which the roentgenologists have considerable difficulty ruling in or out disease but I take it from the fluoroscopic note that the stomach was normal. This I think is the ulcer that was described and it would be quite impossible for me to tell whether it was in the duodenum or pyloric valve. This appears to be the first portion of the duodenum here. They said it did not fill so I have to assume that that is not the duodenum although it looks like it. If that happens to be the duodenal cap and thus another ulcer this ulcer is in the region of the ampulla of Vater.

DR. WALLACE: It is impossible to tell the relation of course.

DR. HAMPTON: I cannot be sure but I should say that the fluoroscopic note would be more accurate than my opinion here.

DR. WALLACE: The report is a little vague probably because of the impossibility of telling about that.

DR. HAMPTON: They apparently did not see the duodenum at all during the fluoroscopic examination and this film was taken later.

DR. WALLACE: Even so in exploring a case of this sort with the lesion in one's hand it is extremely difficult to tell on which side of the pylorus it may be.

Now we have a seventy-five year old man complaining of gnawing pain in the region of the umbilicus, with a loss of twelve pounds of weight and an unknown lesion in the region of the pylorus. One of his major complaints was abdominal distention and constipation. Constipation is a fairly common symptom in malignant lesions of the stomach. We have had two or three cases that were sent into the hospital with a diagnosis of carcinoma of the colon and proved to have been carcinoma of the stomach. We have persistent gnawing pain relieved only by medication. It is much more suggestive of malignant disease than benign ulcer. The vomiting is of no help one way or the other. Loss of weight is, I believe, merely due to poor ap-

petite and impairment of food intake. The past history has no bearing on the present situation, I believe. The urinary and blood findings, as far as the chief complaint is concerned, are merely evidence of dehydration. The free acid of 60 units is offhand more in favor of ulcer. It is interesting to note how many cases of known malignancy of the stomach have free acid. Dr. Parsons two or three years ago reported a series from this hospital of 230 cases and of that group twenty-eight per cent had free acid in the stomach and it is especially interesting that of all the patients with free acid in the stomach over eighty-five per cent were right at the pylorus. I do not believe that that rules out carcinoma of the stomach.

DR HAMPTON: I think if you take the fluoroscopic note you would have to assume that the patient had a duodenal ulcer. As I see those films there is one other thing that is suggestive. This shadow here. Dr. Holmes, what do you think about it? Does that appeal to you as a lesion?

DR GEORGE W. HOLMES: I think the lesion is in the duodenum and outside the stomach and that there is an ulcer present but whether it is benign simple ulcer or carcinoma, I do not know. I think it is outside the stomach.

DR HAMPTON: If this is a lesion, carcinoma of the pancreas has to be considered.

DR WALLACE: In spite of the x-ray evidence and in spite of the high acid I believe the most likely diagnosis is carcinoma of the stomach but I think it is quite possible that it is a benign ulcer. I should say that my first choice was carcinoma of the stomach.

DR TRACY B. MALLORY: Any comment?

DR WILLIAM B. BREED: It is either malignant or nonmalignant, is it not? Leaving the x-ray out, it seems to me that there is no real evidence that this is a malignant lesion. I am willing, in a sporting way, to take the other side and say that this is an obstructing bleeding ulcer in the duodenum. It happens more often than the textbooks tell us that older people have obstructing, bleeding, benign ulcer with a short history of symptoms.

DR ROBERT S. PALMER: I should think that clinically it would be just the opposite of what Dr. Breed said. He is an old fellow with one year's history of indigestion and a twelve pound loss in weight. It seems to me that obstructing lesion would have to be carcinoma of the stomach.

DR EARLE M. CHAPMAN: The kidneys may enter into this picture. Here is a man who has vomited twice and two days after entry the nonprotein nitrogen is 67 and he put out twenty per cent of the dye in two hours, which

is one-third of the amount that he ought to put out. These findings are compatible with mild uremia. He is an old man and his blood pressure is 150/90, and a certain amount of vascular Bright's disease may have been present, leading to uremia and death.

DR BREED: That brings up another question whether he was observed long enough before operation was undertaken.

DR HOLMES: If we can believe the x-ray findings and the films, the lesion is in the duodenum and not in the stomach.

DR TRACY B. MALLORY: Dr. Kranes, did you see the patient?

DR ALFRED KRANES: I did not see him until the day before he died. He was moribund at that time. The blood pressure had dropped and he was in shock. As far as the diagnosis of the lesion goes, I would agree with Dr. Breed that it was probably benign.

CLINICAL DIAGNOSES

Carcinoma of the stomach
Bronchopneumonia

DR RICHARD H. WALLACE'S DIAGNOSIS

Carcinoma of the stomach

ANATOMIC DIAGNOSES

Duodenal ulcers
Operative incision. Posterior gastroenterostomy.
Bronchopneumonia
Pulmonary edema, bilateral
Arteriosclerosis, aortic, coronary and renal, marked
Cardiac hypertrophy
Nephritis, chronic vascular
Pleuritis, chronic fibrous, bilateral
Prostatic hypertrophy, lateral and median lobes
Prostatic calculi
Double ureter, bilateral
Operative scar. Empyema incision, left

PATHOLOGIC DISCUSSION

DR MALLORY: I do not believe I can tell you what the house service really thought about it. In one place the diagnosis was put down as carcinoma of the stomach and in another as ulcer of the duodenum. On the death certificate it was cancer, the preoperative diagnosis was duodenal ulcer and the postoperative diagnosis was duodenal ulcer. I suspect there was a division of opinion on the wards.

He was operated on by Dr. Arthur W. Allen, who found an indurated area definitely beyond the pylorus and did a posterior gastro-

enterostomy, following which the patient very rapidly went into collapse and died in about thirty six hours.

The autopsy showed two ulcers of the duodenum and a negative stomach. Bearing out Dr. Chapman's idea, he had very atrophic kidneys, weighing only 160 grams, which showed a fairly marked degree of vascular nephritis. He also had a severe grade of sclerosis of all his coronary branches and patchy fibrosis throughout the myocardium without any definite infarcts.

that I think a little uremia and a good deal of myocardial insufficiency and some postoperative shock probably all contributed to his death.

DR. HAMPTON: Where was the second ulcer? Was it low?

DR. MALLORY: No, both were within a centimeter of the pyloric ring. One was a centimeter and the other a centimeter and a half in size, each with undermined shaggy edges, with a great deal of fibrosis at their bases. There was no perforation.

CANCER RESEARCH

FIFTEEN years ago laboratory research in cancer had reached a point where it was known that cancer could be caused at any time, (1) by repeated applications of tar to the skin of the mouse (2) by transplantation of cancer cells from one animal to another of the same species, (3) by breeding special lines of mice that inherit a tendency to special cancer, and (4) by inoculating fowl with cell free filtrates of the Rous sarcoma. Clinically, of course, other irritants and conditions were known factors in cancer such, for example, as the overuse of tobacco, repeated sunburns and radium and x-ray. The lines of research developing from the four experimental facts given above have developed an amazing and interesting group of data, but for the most part these lines have tended to keep themselves distinct from each other. The studies

of tar have culminated in brilliant researches begun in London and continued elsewhere and have led to the isolation of many pure chemicals such as dibenzanthracene, that are carcinogenic. The transplantation experiments have made progress, but it has not been so striking. The heredity experiments, especially those of Little and his co-workers, have put this experimental tool on a relatively firm footing. The filtrable virus experiments have been very difficult to understand or explain when compared with the other lines of cancer research.

Now there comes a report from the London Cancer Research group headed by Kennaway and confirmed in Philadelphia that pulls together three of these lines of research into an extraordinary synthesis that opens up great hopes for the future. These workers, in brief, have found that a cancer may be initiated by dibenzanthracene. It may then be transplanted serially through ten different animals thereby diluting the original irritant injected to a point certainly greater than one to one billion, of its original concentration and well below any level that could be identified chemically. At this point they then produce an ultrafiltered extract of the tumor and find that this extract has the power of initiating the same kind of cancer when injected into a new host. This brilliant experiment means that we must postulate that at some time in the course of the growth of cancer a new product is formed by the cancer which is of a size smaller than the size of the smallest visible bacteria and infinitely smaller than the size of a cancer cell, and which may or may not be a living virus which has the property of reproducing in a new host the cancer from which it was derived. This specific reproduction of a special kind of cancer puts it in a different class from the class of substances chemically isolated which produce cancer, but in the same class as the substance transmitting the Rous sarcoma of fowls. The irritant substances, such as the dibenzanthracene mentioned above, produce any kind of cancer of special cell type according to the cells on which they act. They may be either sarcomas, carcinomas, or leukemias according to circumstances.

The development of these lines of research to the point where knowledge is available that is useful in the prevention of human cancer has not yet been reached to an important degree, but with these experimental tools this knowledge may develop almost before we realize it. One would not have to be particularly sanguine to say that actually now the promised land in this field of endeavor is in sight and we have only a few more rivers to cross.

A LIFE TABLE FOR THE TOTAL
UNITED STATES

For the first time in the history of our country, according to the March statistical bulletin of the Metropolitan Life Insurance Company it has become possible to present a life table based on the actual mortality statistics for all of the 48 States of the Union, Texas the last State to be admitted to the Death Registration Area having qualified in 1933. An expectation of life at birth of 61.26 years is shown by this table for the total population both sexes combined. The actual division of this expectation gives to white males 60.86 and to white females 64.40 years.

In 1901, the first year for which an official life table for any considerable part of the United States was constructed, the expectation was only 49.24 years, in fact, the expectation of life at birth in 1901 was less than the expectation of life at the age of 17 in 1933. Putting these changes in another way, we find that according to mortality conditions prevailing in 1901 one quarter of the children born would have died before the age of 25, in 1933 it would take 52 years for this quarter to have died. In 1901 one half of the children born would have died by age 58, and three quarters by age 71, in 1933 these corresponding ages had increased to 68 and 78 years respectively.

Comparing our present figures with other countries in 1933, we find that English males had a birth life expectancy of 58.7 years and German males of 59.8 years, as against our own white male's expectancy of 60.86 years. The corresponding figures for English German and American females are 62.6, 62.6, and 64.40 years respectively. Italy, in 1930-1932 had expectations of life at birth of 53.8 years for males and 56.0 years for females. The life tables of only Norway, Sweden, Denmark and Holland of European countries are as favorable as ours, while New Zealand still exceeds us with an expectation in 1931 of 65.04 years for males and 67.88 years for females.

THE COMPENSATION OF CITY
PHYSICIANS

In the letter of Dr. Bagnall which appears on page 899 of this issue an important subject is presented. It is certainly undignified for physicians to have to agree to the maintenance of medical service under the control of municipalities at the rates set forth in this letter.

The weight of professional opinion should be brought to bear on this subject to the end that justice may be accorded the doctors who are filling these positions.

All interested persons should immediately

give such facts as may be pertinent in this matter to Dr. Bagnall in order to help in promoting the necessary reforms.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

KICKHAM, C. J. E. A.B., M.D. Harvard University Medical School 1927. Assistant Urologist, Carney Hospital. Assistant Visiting Urologist, Pondville Cancer Hospital at Norfolk. As sociate Consulting Urologist, Quincy Hospital. Address 12 Bay State Road, Boston, Mass. As sociated with him is

WELCH, NORMAN A. M.D. Tufts College Medical School 1926. Visiting Physician, Carney Hospital. Junior Visiting Physician Boston City Hospital, Fifth Service. BREECH DELIVERY I

Since it is practically impossible to condense the important features of breech delivery into the space allowed for one presentation in this column, the present discussion will be divided into two parts: the first concerned with the principles underlying the management of breech labor, and the second describing the technic of extraction.

Delivery of the infant by the breech results in about four per cent of all labors and in approximately three per cent of labors at term. This mechanism is notorious for the high stillbirth and neonatal death rates which are associated with it, and calls for the best possible judgment and skill if the birth of a living and uninjured infant is to be attained. The best results can be secured only with the realization that breech delivery is a major obstetrical procedure, and that the inexperienced physician should call a well-trained consultant for the purpose. At the Boston Lying-in Hospital a series of 711 uncomplicated breech deliveries of mature babies has resulted in a crude mortality of 9.5 per cent, which, when corrected by exclusion of macerated and grossly malformed infants, can be reduced only to 6.9 per cent.

Several reasons suggest themselves as contributing to a high risk to the fetus:

- 1 The inherent mechanism of breech birth. It must be remembered that this is composed of three subsidiary mechanisms: those of the breech (or hips), of the shoulders, and of the aftercoming head, respectively. Passage of the breech through the pelvis and over the perineum does not indicate that the shoulders will necessarily follow normally; delivery of the shoulders does not necessarily forecast normal expulsion of the head.

- 2 Protrusion of the umbilical cord, either evident or concealed, is five times as common in breech as in cephalic delivery.

- 3 There is a definite tendency for the placenta to separate prematurely during the second stage of labor after the breech, body, and shoulders, constituting the main bulk of the fetal mass, have passed through the cervix, leaving the aftercoming head inside the uterus.

- 4 The infant may be fatally traumatized by unskilled or improperly timed efforts at extraction.

Any policy or technic of breech delivery, to be successful, must be based upon the following principles:

- 1 Adequate and accurate antepartum examination.

- 2 Essential hospitalization of the patient for delivery, either by bringing her to a hospital, or by bringing full hospital facilities to her at home.

- 3 Constant personal supervision of the patient throughout labor.

- 4 The presence, at delivery, of a competent anesthetist, preferably a physician with obstetric training.

- 5 Ability of the obstetrician to perform successfully the operation of breech extraction when the indication arises.

These principles may be reasonably translated into the following rules:

- 1 The conformation of the maternal pelvis must be thoroughly studied by external and internal mensuration according to the usual clinical standards. Even moderate contraction of the pelvis in a primigravida is much more serious to the infant when it presents by the breech than when it presents by the vertex, as in the former case a test of labor to determine a moot point of cephalopelvic disproportion is obviously out of the question. X-ray measurement of the fetal head, when available, combined with clinical measurement of the pelvis, under an anesthetic when necessary, is of great value in the borderline case, and may indicate clearly the advisability of delivery by abdominal cesarean section.

- 2 The patient should be delivered in a hospital, whenever possible, since such an environment makes possible a rapid change in policy should emergency arise.

- 3 The obstetrician should be in constant personal attendance on the patient from the time active dilatation of the cervix starts until delivery has been accomplished.

- 4 A competent anesthetist-assistant should be immediately available during this time, and should be in actual attendance during the entire second stage.

- 5 The fetal heart rate should be recorded at least every fifteen minutes during the first stage with membranes unruptured, immediately after rupture of the membranes, every five minutes after rupture, and after each pain during the second stage.

- 6 The obstetrician should scrub and maintain surgical asepsis from the time the breech passes through the os until delivery is complete. From this moment on, should there be any delay in expulsion at any time, or

*A series of short selected articles by members of the Section is being published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

should the fetal heart vary in rate outside the normal limits of 120 to 160 beats per minute he should extract the fetus at once under full surgical anesthesia.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning May 3

Berkshire

Thursday May 7 at 4 30 P.M., at the House of Mercy Hospital Pittsfield Subject Lung Diseases (Surgical) — (a) Empyema (b) The Value of Surgery in Chronic Lung Disease Tuberculosis, Lung Abscess etc. Instructor J W Strieder Melvin H. Walker Jr., Chairman.

Bristol North

Wednesday May 6 at 7 30 P.M. at the Mortu Hospital, Taunton Subject Pediatrics (Surgical) — Abdominal Disease in Childhood Instructor J W Chamberlain Arthur R. Crandell Chairman.

Bristol South (New Bedford Section)

Friday May 8 at 4 00 P.M. at the St. Luke's Hospital New Bedford. Subject Diseases of the Liver — Surgical Problems in Diagnosis of Acute Disease of Gall Bladder and Liver Instructor H M. Clute Harold E. Perry Chairman

Franklin

Wednesday May 6 at 8 00 P.M. at the Franklin County Public Hospital Greenfield Subject Syphilis — Its Complications and Treatment Instructor A. W. Cheever Halbert G. Statton Chairman

Middlesex North

Friday May 8 at 7 00 P.M., at the Lowell General Hospital, Lowell. Subject Immunology—Latest Developments in Immunization Smallpox, Typhoid, Measles, Scarlet Fever Diphtheria, Whooping Cough and Infantile Paralysis Instructor O W Anderson Leonard C. Dnrsthoft Chairman.

Norfolk

Friday May 8 at 8 30 P.M. at the Norwood Hospital Norwood Subject Pediatrics (Medical) — The Neonatal State Instructor S H. Clifford H. B. C. Riemer Chairman.

Worcester (Milford Section)

Wednesday May 6 at 8 30 P.M. at the Milford Hospital, Milford. Subject Diseases of the Liver — Surgical Problems in Diagnosis of Acute Disease of Gall Bladder and Liver Instructor E. L. Young Jr. Joseph I. Ashkins Sub-Chairman

APPLICATION FOR MEMBERSHIP IN THE ESSEX SOUTH DISTRICT MEDICAL SOCIETY

New England Journal of Medicine,

I am sending the name of a candidate for admission to the Massachusetts Medical Society with the names of the five sponsors according to the resolution adopted at the last Council meeting

The application and letters have been sent to Dr Fitz

MISCELLANY

SOLOMON EVEREST 1760-1832

BY ARTHUR H. WARD M.D.

Assistant Physician Boston Dispensary Dermatology Department

Most of the biographies of the early American physicians concern their contribution to the knowledge and advancement of their calling with but passing comment on their other interests. The following biography is that of a man who probably contributed nothing to the then known lore of medicine although the available records show that he was a conscientious and skillful physician of power for good in his little community and an active participant in town state and medical society affairs. Such a man was Solomon Everest, who practiced in the quiet little town of Canton, Connecticut located about fifteen miles west of Hartford.

He was born in Salisbury in the northwest corner of Connecticut on April 11 1760. Little can be learned concerning his father and mother other than their names. Of English stock his immediate forebears came in Saybrook and then moved up in the state settling in Salisbury. His father David Everest was married to Margaret Ferris of Sheffield by the Rev. Jonathan Hulbert on July 11 1754. Of this union there were four children Solomon being the youngest. Eight days after the youngsters' birth his mother died and after waiting a decent length of time his father married again, this time to a Lois Jackson by whom he had ten children.

Probably as soon as Solomon was old enough and most probably to relieve the burden at home, where there were so many mouths to feed he journeyed the twenty miles to Winchester where he became apprenticed to Dr. Josiah Everitt and learned the rudiments of his future calling. Also while there he wooed and won the youngest sister of his preceptor Amella, to whom he was married May 15 1782.

Soon after their marriage Dr. Everest and his bride moved to that part of Farmington which is now Avon where he began his medical practice but

in 1796 he transferred his activities to Canton, where he remained until his death in 1822. Able Brown's General History of the Early Settlers of West Simsbury (now Canton) states, "As a physician and surgeon he had but few equals and educated a number of young men who became eminent in their profession. The public placed so much confidence in his professional skill, it was rare that further aid was solicited, even in extreme cases, under his management."

His name appears as one of the original members of the Hartford County Medical Society. Becoming a member of the Connecticut State Medical Society in 1793, a year after its inception, he took an active part in its proceedings, and was given the degree of M.D. by the Society in 1814. He was one of the leading citizens of the town, the incorporation of which was due largely to his effort. He was a member of the convention that formed the Constitution of the State of Connecticut in 1818, in that convention his name is found as voting for and against many of the amendments offered to the proposed constitution, and in the final vote for the constitution as amended he cast his vote in the negative because of his opposition to that section providing that the General Assembly be held alternately in Hartford and New Haven. He was deeply religious but without enthusiasm and austerity, strictly orthodox in the sentiments of the denomination to which he belonged, and for twenty years officiated as a deacon of the First Congregational Church of Canton.

The chief interest in writing this biography, however, lies not in what he did during his life, but rather in the influence he had after his death. He died on April 3, 1822, and when his will was read, it was found he had bequeathed one-half of his estate amounting to \$30,000 in the following manner: of four equal parts, two went to the American Board of Congregational Foreign Missions, one part to the Missionary Society of Connecticut, and one part constituted a trust fund, the income of which was to be used "for the purchase of Bibles, religious tracts, etc., for distribution, for the support of the Domestic Missions in this State, or for the education of indigent, pious youth for the gospel ministry, to any and all of the above purposes, as shall be thought most expedient by a Committee which the General Association of the State of Connecticut shall from time to time appoint for that purpose." The executor took seven years in settling the estate, and at that time turned over \$4,000 to the Committee of the Association. This became known as the Everest Fund. In 1843 his widow died, and her last will and testament was couched in the same identical language, and added \$3,500 to the Fund. The trustees of the Everest Fund early realized the need of educating needy young men for the ministry, so that during the last century the foresight of a comparatively unknown physician has enabled many men to enter the ministry and carry the Christian religion to all corners of the earth to China, India, Bohemia (now Czechoslovakia) and the north- and south-west

portions of the United States. One who received aid from this fund later became President of Oberlin College, another became the much beloved Professor of Mental and Moral Philosophy at Amherst, while still another, an American-born Italian, became prominent in carrying on the religious education of the numerous Italians in Connecticut, thus enabling them to become better American citizens. These are but a few of the more than four hundred who have received a helping hand from a man who realized the necessity of educating young men for the purpose of carrying his ideals to others.

LYNN CANCER CLINIC*

BY WILLIAM T. HOPKINS, M.D.
Visiting Surgeon, Lynn Hospital

The Lynn Cancer Clinic is one of the state-aided, diagnostic, cancer clinics, which seeks to offer opportunity for competent diagnosis and advice concerning cancer to all who may desire it, irrespective of their financial condition. The clinic is conducted in cooperation with the State Department of Public Health, under the management of a committee of five local physicians, appointed by the Lynn Medical Fraternity. The funds for operating the clinic are chiefly derived from legislative appropriation to the Department of Health of the Commonwealth. The Lynn Community Fund Association usually makes an annual allotment to the clinic. Occasional small contributions are made by grateful patients.

The chief expenditures are for salaries to the social service worker and clerk, for expense of follow-up visits, occasional special diagnostic service, and for office supplies.

The Lynn Hospital furnishes, without charge, a meeting place for the clinic with equipment for examinations, including the services of nurses, also, upon request of the clinic, free x-ray diagnostic service for those unable to pay.

The professional staff of the clinic consists of eighteen doctors assigned to regular terms of service and, upon call, the entire staff of specialists at the Lynn Hospital, all giving their services without compensation.

The clinic has been in continuous operation since April, 1927, and meets each Friday morning at ten o'clock at Lynn Hospital. The group system has been in effect for the past year. By this plan, three doctors see each patient before a diagnosis is recorded. Anyone may come to the clinic as a patient and no charge for consultation has ever been made in this clinic up to the present. It is most desirable that patients come upon the recommendation of the family doctor, either accompanied by the doctor, or with a letter from him containing a brief history of the case. If the doctor accompanies the patient, he is invited to join the consultation upon his patient. If a person is found to be afflicted with cancer, the family doctor is so notified at once by letter and the patient is sent back to his care.

*D. Livered at a meeting of Lynn Cancer Cooperative Committee at Lynn Y. M. C. A. Hall February 21, 1936.

The social service worker follows up all cases of cancer attempting to assure adequate treatment at the earliest possible date and by followup of forts keeps in touch with the patient thereafter.

The committee realizes the magnitude, and the seriousness of the cancer problem, the responsibility for dealing with which rests by no means solely upon the medical profession but on account of the great and increasing prevalence of the disorder is a matter which concerns the entire community.

The hopeful feature of the situation lies in the fact that the traditional opinion, that all cancers are hopelessly incurable, is a mistaken one. Of the truth of this statement, I hope to be able to convince you from a brief account of the experience of this clinic.

By microscopic examination of a bit of tissue a competent pathologist can tell not only whether the specimen is cancer but also the kind and grade of malignancy. This is useful from the standpoint of prognosis and in deciding how extensive an operation must be undertaken.

In order to determine how many cancers appear to be cured it is necessary first to be certain how many are, in fact, cancers. To be as certain as possible upon this point the clinical diagnosis of cancer by three of the clinic staff doctors is reinforced by the report of the pathologist upon the specimen removed. Reports for this clinic usually are made by the Cancer Commission of Harvard University and are checked against the clinical diagnosis with which they must agree for the final record. The average duration of life of a cancer patient, after the appearance of symptoms is about two years if untreated or inadequately treated.

From the date of opening of the clinic to January 1 1936 the clinic has examined 2,841 patients. Of these 629 have been found to have cancer. As of January 1 1936 the clinic is able to show 109 cancer patients living five years or more after treatment and free from evidence of the disease. These are sometimes referred to as five-year cures. This period being chosen because freedom from recurrence for this length of time usually means permanent freedom from recurrence. It seems to us that these figures speak for themselves. It should furthermore be realized that all of these 109 five-year cures come from cases visiting the clinic prior to January 1 1931 and in all probability many seen since that date and included in the total of 629 are also on their way to become five-year and we hope permanent cures.

The one point upon which we are utterly dissatisfied is the long period of delay by the patient after discovery of symptoms, before consulting a physician. This should be counted in days whereas it may now be reckoned in terms of months. Practically all our cures are of cases seen early in their course. After the disease has established secondary deposits of cancer cells, the situation is less hopeful. Patients are coming to the clinic not much

earlier in the course of the disease than was the case eight or nine years ago.

The clinic wishes gratefully to acknowledge the splendid coöperation of the Lynn Hospital which has made possible such success as the clinic has achieved and especial emphasis should be placed upon the public spirit and unfailing courtesy of the press which always publishes our bulletin as news. A considerable proportion of the clinic cases has come to us from newspaper publicity and it cannot fail to be a source of satisfaction to the publishers to be made aware that their generosity in this regard has resulted in the saving of some lives.

No attempt has been made to estimate the percentage of cancers which may be regarded as curable but it seems to have been demonstrated that not all cancers are inevitably fatal.

This in brief, is the evidence which the Lynn Cancer Clinic is able to lay before you.

"OUR COMMON DRINKING CUPS"

BY CHARLES F. BOTSFORD, M.D.

Retired Health Officer Hartford Conn.

Many years ago public sentiment recognized the danger of the transference of disease through what was called the common drinking cup and laws were passed requiring the use of hubbler fountains or single service containers in certain public places. The repeal of the Eighteenth Amendment and the accompanying increase in places of public entertainment have forcibly brought to our attention the fact that in many of our public eating and drinking places utensils and especially glasses receive so slight an amount of cleansing between services that they are as important a means of spreading those diseases in which the germs are taken into the body through the mouth as was the old fashioned drinking cup.

Some of our social customs greatly contribute to this condition. Custom requires that beer be served in a wet glass and the bartender usually takes a glass just returned to the counter rinses it in water which may have been changed only three times a day fills it with beer again and starts it on its way. The mucus from the mouth is so tenacious that a rinse in warm or even fairly hot water even containing soap or other cleansing agent, has almost no effect upon it, and whatever germs have been left by previous users are passed on to those who follow. A wet glass may look quite clean, but the same glass dried presents a different appearance frequently showing not only finger prints of previous users but a gray rim of mucus around the edge. Nothing short of the application of considerable force by a brush or similar means and the use of really hot water and soap or still better one of the modern cleansers, will remove this deposit. The emphasis of state and local health regulations has been on the equipment and general cleanliness of eating and drinking places in the belief perhaps mistaken that proper equipment always produces the desired result, possibly also because it is easier

to check on equipment than on performance. Thus, the standard regulations stress the protection of food and drink from dust and flies, proper refrigeration, a safe water supply, convenient toilets, and in most cases facilities for heating water, and the equipment necessary for washing utensils in the traditional household way. The inspector can check all these things and the general appearance of cleanliness on his rounds, and if it scores well, the place is considered satisfactory. The requirement of a standard minimum of equipment has done much in a general way to increase the safety of places selling food and drink. We no longer have frequent epidemics of typhoid due to a poor water supply or carried to the food by flies, and outbreaks of food poisoning from the use of spoiled materials are now rare.

The use of laboratory methods to check the efficiency of dishwashing from the standpoint of the removal of the really dangerous germs on the dishes has only recently been applied to utensils in places of public entertainment, although it has been used in the milk industry for some years, and standards of reasonable cleanliness for milk bottles have been established. The examination of more than five hundred glasses from taverns, soda fountains and restaurants by the laboratory methods used for milk utensils shows that only 8 per cent of glasses from taverns, 22 per cent from soda fountains, and 35 per cent from restaurants met the standards of cleanliness established for milk bottles. Included in this group were those restaurants using machine washing. Of these 61 per cent were satisfactory. Of course, this does not mean that all the germs found are harmful. Fortunately, most of them are not. This is simply a method of accurately testing dishwashing efficiency, and when a few eating places uniformly wash their utensils so clean that no germs can be cultivated from 95 per cent of them. It shows that results considerably better than the standard are at present not attainable. Moreover, other tests made show that the kinds of germs found vary with the time of year, and are similar to those found in the throats of sick people in the community at that particular time, so that the conclusion is inescapable that these utensils might be an active means of spreading these diseases.

We believe that the public drinking place is so closely tied up with our social life that it cannot and should not be done away with, so that the question remains, what can be done to make it as safe as possible?

One solution would be the use of paper or similar single service utensils, but paper is a poor substitute for glass or china, and few of us would wish to use it, except in a special emergency. The alternative seems to be the general recognition of the fact that because of their use by so many people, and because many places which appear very clean, have very poorly washed dishes, methods of cleansing of a much more thorough nature than those in use in an ordinary household must be developed.

Public health authorities must, with the help of the laboratory, work out practical means of dish washing which will be efficient, and the public must be educated to demand their use. Each official inspection will then include the taking of a sample glass and spoon or fork for laboratory analysis. At present it appears that those places using machine dishwashing are much safer than those washing in other ways.

DR. LAHEY ADDRESSES THE PHILADELPHIA COUNTY MEDICAL SOCIETY

Dr. Frank H. Lahey gave the Sixth Annual J. Chalmers Da Costa Foundation Oration before the Philadelphia County Medical Society at the Bellevue Stratford Hotel, Philadelphia, on Wednesday evening, April 22. Dr. Lahey's subject was The Management of Biliary Tract Disease.

FIVE-YEAR RESIDENT INFANT MORTALITY RATE IN BOSTON

1930-1934

MARGARET H. TRACY, *Executive Secretary*
BOSTON HEALTH LEAGUE

The tables appended show the resident births and infant deaths from 1930 through 1934 in the city of Boston and the five-year average infant mortality rate. The resident infant mortality rate for the city each year during this period is as follows:

1930	66.6
1931	59.4
1932	57.5
1933	58.9
1934	53.3

The greatest decline in the total city resident rate occurred in 1931. The decline in 1932 was offset by the rise in 1933, but in 1934 there was again an appreciable decrease which is especially encouraging in view of the fact that there was an increase in the infant mortality rate for the country as a whole. "Practically the entire region lying east of the Mississippi River was adversely affected. Of the twenty-six states comprising this area, twenty-one recorded higher infant mortality figures in 1934 than in 1933. Only five eastern states, Massachusetts, New York, Rhode Island, Vermont and West Virginia, succeeded in maintaining or improving their records of the previous year. Of these, Massachusetts made the best showing, having reduced its 1933 infant mortality by nearly 5 per cent in 1934."* Boston reduced its infant mortality rate by 9 per cent, a much greater reduction than that for the state as a whole.

The provisional infant mortality rate for Boston, issued by the City Health Department January 1, 1936 for 1935 is 50.7, which again shows a decline. In view of continued unemployment and the large proportion of families receiving relief, physicians

and official and voluntary agencies giving prenatal and obstetrical care are to be commanded

Examination of the five-year average infant mortality rate by Health and Welfare Areas indicates that East Boston Charlestown South End South Boston and Roxbury are the five areas where the rate is above that for the city as a whole. In general, these areas are congested, have low rentals and a high proportion of families on relief, but these economic factors alone do not account for the higher rates. Economically the West End, which has had an exceptionally low rate for the five years and the

North End, where the rate is nearly equal to the city rate for this period closely parallel the five health and welfare areas where the rates are higher. The amount and quality of prenatal care, the quality of delivery and the care of the new born infant in the areas having a high infant mortality rate might well be studied to determine what might be done to lower the infant mortality rates in these areas further. Thus the city rate might be still further reduced.

Metropolitan Life Insurance Company Statistical Bulletin,
September 1935.

CORRESPONDENCE

CITY PHYSICIANS COMPENSATION

April 16 1936

Editor *New England Journal of Medicine*

The matter of City Physicians' compensation has received some consideration by the Haverhill City Committee of the Essex North District Medical Society. It was found that the gross yield in Haverhill to City Physicians is 14¢ per visit the other cities in this district vary from 6½¢ to 46¢ per visit. The mayor of Haverhill in preparing his annual budget asserted that the costs were too high and must be pared down. The physicians on the staff of the Haverhill Municipal Hospital contributed more than \$30,000 worth of service last year.

The principle of continuing City Physicians on this basis has been disapproved by the Massachusetts Medical Society and by the Commissioner of Public Health of Massachusetts. I should like to stimulate through your columns the interest of City Physicians throughout the state in studying the scope and compensation of their work with the object of obtaining figures which might be helpful, and indicating a satisfactory solution for the evils inherent in this branch of medical care. I should be glad to hear from any City Physicians who are interested.

Very truly yours

281 Main Street, E. S. BARNALL, M.D.
Groveland Mass

THE TREATMENT OF SYPHILIS WITH ARTIFICIAL FEVER

The Commonwealth of Massachusetts
Department of Public Health
State House Boston

April 22 1936

Editor *New England Journal of Medicine*,

The State Departments of Mental Diseases and Public Health have installed two hattering Hyperthermia units at the Boston Psychopathic Hospital for the treatment of syphilis with artificial fever. The Boston Dispensary has delegated a nurse to operate one of the units. These two machines have been in operation a year for the treatment of selected cases.

It is now possible to offer the service of these machines to the medical profession of this State so far as treatment days are available. Physicians having patients who may benefit from fever therapy are invited to confer with Dr. Harry C. Solomon, Director of Therapeutic Research at the Boston Psychopathic Hospital who will also represent the Boston Dispensary in the admission of patients to be treated in one of the units.

A considerable number of treatment days are available for the treatment not only of neurosyphilis but for other forms of the disease such as interstitial keratitis, optic nerve involvement, other eye conditions due to syphilis, gummatous syphilitic ophthalmitis, or any clinically active systemic syphilis except cardiovascular.

All patients referred for fever therapy must be accompanied by full records of history, diagnosis, serology, treatment, complications, reactions, and the result of a spinal fluid examination. If a lumbar puncture has not been done, the patient must agree in advance before treatment is begun.

The physician who refers the case may be asked to report the condition of the patient and any subsequent treatment at intervals during the following five years or will be expected to permit the representatives of the Psychopathic Hospital or Boston Dispensary to acquire such information as may be necessary from the patient and the patient's record.

Yours truly

HENRY D. CHADWICK, M.D.,
Commissioner of Public Health
WYNDER OVERHOLSER, M.D.,
Commissioner of Mental Diseases

ROUND TRIP TO KANSAS CITY
BY AEROPLANEEditor *New England Journal of Medicine*

The round trip fare to and from Kansas City via the Transcontinental and Western Air Inc. is \$142.55. However by buying \$500 worth of scrip the trip is reduced another fifteen per cent. This scrip need not be used by one person but may be used by several persons. In other words if several persons desiring to travel by air (and save 48 hours) would get together the trip would cost them around \$121.00. This amount is only slightly more than a round trip by rail. I myself, wish to go by air and there most be others who plan to do so likewise. Would it not be possible for you to verify the above facts, perhaps make it generally known and enable us to benefit by that extra fifteen per cent?

EARL R. LEITCHER, M.D.

472 Commonwealth Avenue Boston

April 20 1936

PRO DOMO SUA

Editor *New England Journal of Medicine*

My attention has been called to the 1935 *Year Book of General Surgery* in which Professor Graham after a relatively lengthy quotation from my paper "Is Total Thyroidectomy Rational as a Method of Treatment?" has made the following remark in parentheses (According to the 1934 *A. M. A. Directory* the author is an ophthalmologist. It is to be feared such comments will not clarify the situation materially. "Shoemaker stick to your last" is obviously as appropriate today as when first uttered by Apelles over 2,000 years ago. Ed.)

I have been overcome by the honor of being quoted by so eminent a surgeon. My best dreams could not reach so far. However the remark in the parentheses has spoiled the froth. Time and again I am reminded that I am an ophthalmologist, and that the subject of Total Thyroidectomy is none of my business.

There was a time when a jeweler prescribed glasses (not a shoemaker) and a barber posed as a surgeon and a dentist. But that time has gone by. Now

we all get medical education, and we are intelligent enough to be able without using inappropriate sayings and comparisons to accept or reject arguments dealing with a scientific problem

I regret that Professor Graham did not have time, space, or willingness to quote those parts of my paper which were based on the work of the great surgeon Kocher. Had he done so, he might not have said that "such comments will not clarify the situation materially"

The subject of Total Thyroidectomy is not a technical surgical problem. It is of interest to the cardiologist, surgeon, general practitioner, neurologist, psychiatrist, physiologist, pathologist, endocrinologist and, *horribile dictu'* even to the ophthalmologist. It is known that the thyroid and the pituitary, if diseased, sometimes may affect the eye.

If Professor Graham read the last paper of Clark, Means and Sprague² and my letter,³ he could see that time has proved, strange as it may seem, the contentions of the ophthalmologist to be correct. One thing is clear to me: *The bright perspectives of three years ago have dwindled to a selection of a very small group, and the Almighty alone knows how to select this group.* Clark, Means and Sprague are reluctant to say that they know.

Consequently, the number of wrongly selected cardiac patients, if the procedure is continued, will swell the number of unfortunate victims. The Peter Bent Brigham Hospital (a pioneer in this field) has performed only three operations during the last year.⁴ The Massachusetts General Hospital has performed no total thyroidectomies during the past six months.⁵ It is significant.

RECENT DEATHS

LINES—ERNEST HOWARD LINES, M.D., the retired chief medical director of the New York Life Insurance Company, died April 17, 1936, at the home of his daughter, Mrs. Sargent H. Wellman, of Topsfield.

Dr. Lines was born in East Otto, New York, in 1859, and was a graduate of the College of Physicians and Surgeons of New York.

During the war, he served with the American Ambulance Field Service and later, becoming interested in the education of the wounded French soldiers, was director of the Quai de Billy School conducted by the Union des Colonies Etrangères and received the decoration as Chevalier of the Legion d'Honneur.

BALLOU—ANDROSE ROCHE BALLOU, M.D., of 280 Neponset Avenue, Dorchester, Massachusetts, died suddenly December 4, 1935, aged fifty-four.

Dr. Ballou was born in Quincy, Massachusetts, and acquired his medical education at the Baltimore

Medical College, graduating therefrom in 1905. He settled in Dorchester where he practiced up to the time of his death. His memberships included the Massachusetts Medical Society which he joined in 1907.

His widow, Mrs. Katherine G. Ballou, a daughter, Alice Noel Ballou, and three brothers, John R. and Arthur C., both of Quincy, and the Rev. Marcian L. Ballou, of Kearney, Nebraska, survive him.

GALE—GEORGE WASHINGTON GALE, M.D., of 68 Lincoln Avenue, Saugus, Massachusetts, died April 21, 1936. Dr. Gale was born in Exeter, N.H., ninety-nine years ago. He was active in the practice of medicine until two years ago.

After graduating from Phillips Exeter Academy in 1850, and the Berkshire Medical College in 1861, Dr. Gale served as a Civil War surgeon with a naval assignment. After his discharge from war service, he practiced in Saugus and Lynn until he retired two years ago.

Dr. Gale had held membership in the General E. W. Hinks Post 95, G. A. R., acting as its secretary. He was also a member of the Massachusetts Medical Society and the Masonic order. In April 1930, a bronze medallion was presented, by the New England Medical Center, to Dr. Gale as the second oldest family physician in New England.

RUSSELL—EDWARD M. RUSSELL, M.D., aged sixty-eight, a retired ear and nose specialist of 38 Berkeley Street, Springfield, Massachusetts, died in that city, April 20, 1936, after a short illness.

He was born in Springfield, graduated from Holy Cross College in 1890 and from McGill University Faculty of Medicine in 1901. Dr. Russell is survived by two brothers, Dr. Simon J. Russell, and Mr. Thomas S. Russell, both of Springfield, two nieces and five nephews.

OBITUARY

A TRIBUTE TO DR. FRANCIS GEORGE CURTIS

Dr. Francis George Curtis died in Ashfield, Mass., on April 7, 1936, in his seventy-ninth year, having practiced medicine in Newton for nearly fifty years.

His father, George William Curtis, was an extraordinarily brilliant man. At an early age he was a member of the famous Brook Farm Colony at West Roxbury; he was the Editor of *Harper's Weekly* and for many years the Editor of the "Easy Chair" of Harper's Magazine; he was one of the early Abolitionists, one of the Founders of the Republican Party, wrote several noteworthy books, and was considered one of the best orators of his day.

His mother, Anna Shaw, was a sister of Robert Gould Shaw, whose monument by St. Gaudens is opposite our State House.

Curtis attended St. Paul's School at Concord, N.H., graduated from Harvard with the class of 1879, and took his medical degree at the College of Physicians and Surgeons (Columbia) in 1883. In 1887 he settled in Newton and at one time acted as Superintendent

tendent of the Newton Hospital. In 1894 he was appointed Chairman of the Newton Board of Health a position he held for forty two years. In this work Dr Curtis made a national reputation. His single-handed fight to compel milk dealers to furnish clean milk to Newton thus markedly reducing the infant mortality his common sense innovations concerning fumigation and his insistence that children were safer in school, during epidemics than playing on the streets or congregating in playgrounds were a few of the outstanding accomplishments of his work which gained him the name of being one of the most progressive health officers in the country.

In the Newton Medical Club Dr Curtis had a host of friends and was always an enthusiastic attendant at its summer outings.

We, the members of the Newton Medical Club wish to record our appreciation of Dr Curtis as a man, as a physician and as a friend and take this means to convey our deep sympathy to his widow and children.

Medical Conference Program
9-10 A.M., May 1938

Friday May 1—Certain Aspects of the Thyroid Dr David Rapport.
Saturday May 2—Hospital Case Presentation. Dr S J Thannhauser
Tuesday May 5—Injury and Disease of the Epiphyseae. Dr John D Adams
Wednesday May 6 — Erythroblastic Anemia. Dr James Baty
Thursday May 7 — Endocrine Clinic Dr Charles Lawrence
Friday May 8—The Early Diagnosis of Brain Tumors Dr Olibert Horrax.
Saturday May 9—Hospital Case Presentation Dr S J Thannhauser
Tuesday May 12—Clinical Preventive Medicine Dr Robert W Buck
Wednesday May 13—Hospital Case Presentation Dr S J Thannhauser
Thursday May 14—Effect of Protamine Insulin on the Blood Sugar Case Presentation Dr Harry Blotner
Friday May 15—Thyroid and Psyche Dr James H Means.
Saturday May 16—Hospital Case Presentation Dr S J Thannhauser

Tuesday May 19 — Clinical Diagnosis of Jaundice Dr Howard M. Cline.

Wednesday May 20—Hospital Case Presentation Dr S J Thannhauser

Thursday May 21 — Social Service Case Presentation Miss Edith Canterbury

Friday May 22 — Newer Aspects of Diabetes Dr Reginald Fitz

Saturday May 23—Hospital Case Presentation Dr S J Thannhauser

Tuesday May 26—The Effect of Endocrine Disease on the Cardiovascular System Dr H C Gorham

Wednesday May 27—Hospital Case Presentation. Dr S J Thannhauser

Thursday May 28—Blood Clinic Presentation Dr Isadore Olaf.

Friday May 29 — Observations on the Circulation During Pregnancy Dr C Sidney Burwell.

BOSTON UNIVERSITY SCHOOL OF MEDICINE SURGICAL CLINIC BOSTON CITY HOSPITAL

Dr Philemon E. Truesdale Surgeon in Chief of the Truesdale Clinic in Fall River will talk to the students on Friday May 15 12:1 in the Cheever amphitheatre

The discussion will be opened by Dr William R Morrison, Clinical Professor of Surgery
Physicians and medical students are invited

ASSIGNMENT OF SURGEON FERGUSON BY THE U S P H S

Acting Assistant Surgeon Charles Ferguson has been directed to proceed from Ellis Island N Y to Boston Mass to attend the American Urological Association from May 18-22, 1938 and return April 13 1938

BOSTON PHYSICIANS REPRESENTED AT THE MEETING OF THE AMERICAN HEART ASSOCIATION

Among the contributors to the program of the American Heart Association at the meeting in Kansas City Missouri May 1., the names of Boston physicians appear as presenting papers as follows
Dr Soma Weiss and Dr George P. Robb on Cardiac Asthma (Paroxysmal Dyspnea) and Failure of the Pulmonary Circulation Dr Howard B Sprague on "The Differential Diagnosis of Congestive Heart Failure and Constrictive Pericarditis (Pick's Disease)" Dr James C White on "The Control of Sympathetomized Blood Vessels by Sympathomimetic Hormones and Its Relation to the Surgical Treatment of Raynaud's Disease" and Dr R. H. Smithwick on "Modified Dorsal Sympathectomy for Raynaud's Disease (Vascular Spasm) of the Upper Extremity"

REPORTS AND NOTICES OF MEETINGS

ROBERT B BRIGHAM HOSPITAL CLINIC

A clinic on Still's Disease was held March 18 at the hospital. Four patients were shown. The first, an eleven year old boy, developed polyarthritis at the age of six, and practically every joint was involved. The second patient was a sixteen year old girl whose illness started three years ago with slight symptoms in the ankles and wrists. She had lost thirty five pounds but had regained fifteen. The third patient was an eleven year old girl whose illness started at the age of four. A synovectomy was performed on the left knee in 1931, while the right knee was treated with x-ray. It was shown that the knee treated with x-ray was much the better of the two. This girl had made remarkable recovery from a process which involved practically every joint in her body. The fourth patient was a thirteen year old girl whose symptoms started at the age of ten. She has had a persistent swelling of the right hand. During the six months she has been in the hospital there has been no advance in the arthritic process.

Still in 1897 described an arthritis affecting children characterized by enlargement of the spleen and lymph nodes. The disease is not common. Probably less than one per cent of all patients with arthritis may be said to have this form of the disease. From our present knowledge of arthritis it is best to consider this process a rheumatoid arthritis occurring in childhood. It is not essential to have enlargement of the spleen and lymph glands to make the diagnosis. In the four cases mentioned above two had palpable lymph nodes, and none had enlargement of the spleen. The increase in size of the spleen is probably an early manifestation of involvement.

The cause of Still's disease being unknown, the treatment is based essentially upon restoring the functional level of the body to the highest possible degree through adequate supervised rest, proper diet, protection for the joints to prevent deformity and graded exercises supplemented by physiotherapy and hydrotherapy. A Hubbard Tank has recently been installed in this hospital, and it is felt that under water exercises are of great value in bringing about improvement.

At the close of the clinic the histories of several patients were reviewed who had been restored to usefulness and independence after having been severely crippled by this type of arthritis. Patience and persistence with careful supervision over a period of years make it possible to achieve satisfactory results in the majority of cases.

NORFOLK DISTRICT MEDICAL SOCIETY

The second Conference of the Insurance Company Executives, Hospital Executives, and Physicians was held at the Boston Medical Library, on January 17, 1936 at 12:00 M. The following were present:

Mr William P. Cavanaugh, of the National Bureau Casualty & Surety Underwriters, of New York, representing the Bureau group, who came here expressly for the purpose of attending this conference, Mr P. W. Linscott, of the Employers' Liability Assurance Corp., Ltd., representing the Non-Bureau group, Mr Charles E. Wilde, of the Liberty Mutual Insurance Company, representing the Mutual group, Dr Henry M. Pollock, Supt. Mass Memorial Hospitals representing the Hospital Executives Association group, Dr Charles E. Mongan, President Massachusetts Medical Society, Dr A. S. Begg, Secretary, Massachusetts Medical Society, Dr Charles C. Lund, representing the Suffolk District Medical Society and Dr Henry M. Landesman, representing the Norfolk District Medical Society.

The chairman made the following introductory remarks:

"Gentlemen,

"We are now here in a small but representative group to formulate an agreeable and workable plan for the benefit of the Insurance Companies, Hospitals, and Physicians without harm to the Patient, and the Lawyer.

"From a careful study of the situation I cannot see why it is not the best policy for all concerned to work harmoniously. You gentlemen from the insurance companies seem to have agreed that there have been unnecessary abuses perpetrated by patients or lawyers, and sometimes both. As far as you were concerned, you really had no hand in it. From my knowledge of the situation, the bills of the physician and/or hospital were always taken into consideration as part of your settlements.

"We here present know exactly what the situations have been. There is really no need of going through it all over again.

"There is but one thing for us to do, and that is to agree on a plan. If the plan which I presented at our last conference does not exactly cover the situation, let us, if we can, create one which will.

"Now, I believe, we are ready for action."

Dr Pollock opened the discussion. He was of the opinion that according to an old law, the hospitals and physicians are actually protected in the payment of their bills, by the "Uniform Policy Law."

THE UNIFORM POLICY

It is understood that all policies were made uniform in 1935.

I. Coverage 'A' provides—"To pay on behalf of the insured all sums which the insured shall become obligated to pay by reason of the liability imposed upon him by law for damages to others for bodily injury, including death at any time resulting therefrom, or for consequential damages consisting of expenses, incurred by a husband, wife, parent, or guardian for medical, nursing, hospital, or surgical, service in connection with or on account of such bodily injury or death."

Dr Pollock continued. Assume that the physician or hospital should bill the insured for services rendered say sending the bill by registered mail with a return receipt to the insured with a copy thereof to the insurance company and should look to the insured rather than to the patient for payment, would not the insured under Chapter 146 of the Acts of 1925 be liable for the professional or hospital service rendered and would not the insurance company before effecting a settlement see that reasonable bills so rendered were paid?

"Would not the insurance company under its contract with the insurer be liable for such bill?

Mr Wilde, Mr Cavanaugh, and Mr Linscott from the insurance group discussed the above "Uniform Policy" but there was a question of doubt whether this would hold.

Mr Cavanaugh stated that they have a lien in New York City. The medical societies have made an agreement with the insurance companies and are protected in their bills.

Mr Wilde and Mr Linscott felt that on account of the nonexistence of a compulsory insurance law in New York such an agreement could not work in Massachusetts.

The insurance company representatives Mr Linscott, Mr Cavanaugh and Mr Wilde, were convinced that an injustice is being done to physicians and hospitals and this could be remedied without the alternative of having a new law passed, which at times would work out to great disadvantage and incur an unnecessary expense to the insurance companies. They were willing and anxious to get the situation straightened out as soon as possible.

The chairman had hoped that the plan which he had introduced at the previous meeting based on the objections discussed by all concerned and which the insurance companies felt, covered the situation satisfactorily would be adopted but Dr Begg thought it might be better for the insurance companies to present a plan. Then the medical men and hospital executives could take that up and make any suggestions which they felt were necessary.

Mr Linscott said that there were many physicians who caused much trouble by holding up cases with lawyers especially where there were no witnesses, and where there actually were no injuries. Such cases cost the insurance companies a great deal of money. Besides, it was absolutely fraudulent. He said that insurance companies had a list of the doctors who were doing such work and he wanted to know whether such doctors could be punished by the medical societies.

Dr Begg informed him that each county society has a Grievance Committee and the Massachusetts Medical Society has a Committee on Ethics and Discipline that when anyone was found guilty by this Committee the case would be referred to the Massachusetts Board of Registration in Medicine which has the power to suspend or revoke the license of physicians who are found guilty.

A question was asked by one of the physicians as to whether insurance companies could be punished if they did certain things which were not ethical. Mr Linscott replied that a committee would be formed by the different insurance companies to take care of such matters.

The chairman inquired of Mr Linscott whether he had a plan he wished to present at this conference, and he said he thought the plan presented by the chairman was a pretty good one.

Mr Cavanaugh who had just arrived from New York to attend this conference wanted a little more time to acquaint himself with the situation in Massachusetts. He had no definite plan at this time.

The chairman then asked Mr Wilde of the Mutual group whether he had a plan. Mr Wilde said as this was the first meeting that he had attended and as he was taking the place of Mr Cronin also of the Liberty Mutual Insurance Co. who could have spoken for the entire Mutual group that he was unable to do so at this time. He spoke however officially for the Liberty Mutual Insurance Company "that we can agree on a gentlemen's agreement, but the Liberty Mutual stands ready to oppose all lien bills. He was not sure about the Cavanaugh lien which is in vogue in New York City. He thought that it probably would not do here in Massachusetts.

He is convinced that the insurance companies are very willing to cooperate with and protect the physicians and hospitals so far as possible and to pay bills direct to them. Of course certain conditions must be fulfilled by the physicians and hospitals.

- 1 Cooperation of physicians and hospitals in giving insurance companies correct information.
- 2 Cooperation of physicians and hospitals for an arrangement for an early examination of patient.
- 3 Reasonable bills should be presented.
- 4 Physicians should not recommend lawyers when patients are anxious and want to settle cases themselves.
- 5 Physicians should discourage and refuse to accept fake cases.
- 6 Physicians should not interfere in the settlement of cases.

Insurance companies would not be able to take care of the following:

- 1 In cases where there is no liability.
- 2 In cases where there is a question of liability and the settlement is made for a small sum for the purpose of getting rid of a nuisance case. The insurance company can notify physicians and hospitals of such settlements in advance.

He suggested getting an affidavit from the patient authorizing the insurance company and the lawyer to pay the physician and hospital direct when the case is settled.

Dr Lund asked the insurance company representative what the percentage of troublesome cases was, that as far as he knew in his years of practice, he has never had any trouble in collecting his bills.

Mr Linscott replied that there were many, but they came from certain sections of the city. He cited the case of one of his employees, a young lady, whose car bumped or was bumped slightly by another car, no one being hurt. Yet later on, one of the dishonest lawyers sued for seven passengers in the other car. The insurance company had to pay a nuisance value for the seven.

It was agreed by the insurance company representatives, the hospital representatives, and the medical representatives that they are anxious to cooperate and come to a gentlemen's agreement, that a little more time should be taken, and that the insurance companies present a plan to be discussed by the medical and hospital group. Then a final meeting should be held for the agreement.

The chairman agreed to withdraw his House Bill 1045 which covers the lien similar to House Bill 1109 as introduced by him last year, except that it contains reservations to cover the objections of the insurance companies to the bill.

The meeting was adjourned until the insurance companies present a definite plan to be ready within a week.

H M LANDESMAN, M D, *Chairman*

NEW ENGLAND OPHTHALMOLOGICAL SOCIETY

The March meeting of the New England Ophthalmological Society was held at the Massachusetts Eye and Ear Infirmary on March 17, 1936. The first cases were presented by Dr Trygve Gundersen on Corneal Dystrophy. Two cases were shown in which there was a definite corneal haziness of unknown origin, insidious onset, and undetermined classification. It probably represents a hereditary trait and is more closely associated with nodular keratitis than with any other type of corneal dystrophy.

Dr William P Beetham presented a case of sarcoma of the iris. There are two types of this condition: the pigmented and the unpigmented. Of the 100 reported cases about one-fourth are of the non-pigmented type. Some of them start from pigmented nevi; all are considered to be of low grade malignancy. In these cases, the pupil is slightly irregular and dilates poorly in the region of the neoplasm. The use of the slitlamp helps considerably in the diagnosis. Iridectomy may be safely performed if the tumor is small and well localized and if there is good vision in the affected eye. Cases which do not conform to these requirements must have the eye enucleated.

Dr J Heebert Waite spoke on Choroideremia and presented several cases which were at first thought to represent examples of this condition. Each gave a history of gradual onset of night blindness some

years before. Each presented a telescopic field of vision and the fundus showed normal discs and vascular trees with an absence of most of the visible choroid. Each of the three cases shown belonged to the same family. All were markedly myopic, all had vitreous opacities and annular scotomata. Choroideremia is a congenital absence of the choroid and there are about fourteen cases in the literature. Slides of cases of retinitis pigmentosa were shown and the pathology demonstrated. In the latter condition after the epithelium loses its normal pigmentation, a layer of glial tissue is laid down which completely covers the choroid. In the youngest case shown by Dr Waite, there were many areas where the choroid was not entirely covered and, on the basis of this case, he believes that all of the cases are probably retinitis pigmentosa rather than choroideremia as at first suggested.

Dr Harry B Friedgood spoke on "Experimental Exophthalmos." The anatomy of the smooth musculature of the orbit in both animals and man was discussed in detail. In animals there is a cone of smooth muscle surrounding the eyeball with its apex at the base of the orbit. In this cone there is a good deal of elastic tissue. In man there is usually only a small remnant of this cone of smooth muscle. In experimental work it has been shown that this smooth muscle is supplied by sympathetic fibres. Several investigators have shown experimentally that exophthalmos is directly due to the sympathetic stimulation leading to chronic hyperactivity of this smooth muscle cone. A motion picture was shown to demonstrate the effect of stimulation of the sympathetic fibres leading to this muscle, in the case of rabbits. Most investigators who have tried this method of producing exophthalmos in human beings have failed.

Dr Cannon in 1914 succeeded in suturing the phrenic nerve to the peripheral end of the cut cervical sympathetic and thus produced a frequent stimulation of the smooth muscle of the orbit. This caused an exophthalmos to develop. Although it has been very difficult to repeat this experiment because of the technical difficulties involved, it has been done in Dr Cannon's laboratory. Extracts of the anterior pituitary will also produce exophthalmos in guinea pigs when injected over a fairly long period of time. Recently the feeding of a certain species of cabbage has produced this same effect, and it has been found that the chemical compound acetylnitride is the substance in this food responsible for the reaction. The last phenomenon takes place only in immature Dutch rabbits and is inhibited by feeding green vegetables or by cutting the cervical sympathetic or by administering iodine.

After the injection of alkaline extracts of the anterior pituitary body, exophthalmos occurs and the typical changes that take place in the thyroid body in hyperthyroidism may be demonstrated. Certain cases have been observed both experimentally and clinically where patients or animals develop exophthalmos when there is no thyroid present. In animals this may be produced at times by anterior

pituitary extracts after the thyroid has been removed surgically. Dr. Friedgood closed his paper with a plea for more experimental data on this important subject.

Dr. Cannon discussed the paper and emphasized the muscle as being the preëminent factor in causing exophthalmos. He pointed out that stimulation of the cervical sympathetic also causes activity of the anterior pituitary body and of the adrenals.

NEW ENGLAND HEART ASSOCIATION

A clinical meeting of the New England Heart Association was held at the Boston Lying-in Hospital on March 23, 1936. Dr. Burton E. Hamilton presided.

The first paper on the program was presented by Dr. Arthur T. Hertig who spoke on angiogenesis in the early human placenta. Microscopic sections from some of the earliest known human embryos were demonstrated illustrating the development of venous lacunae in the chorionic villi prior to the formation of continuous blood channels.

Dr. A. Hirschelmer presented a series of lantern slides from photographs of the skin of pregnant women taken with infrared light. These photographs brought out to a striking degree the engorgement of the superficial veins in pregnancy. Marked changes were observed between pregnancy and the puerperium in the superficial vessels of the abdomen and to a lesser extent of the legs. Dr. Hirschelmer also reported observations on changes in the blood volume during pregnancy. Determinations with the Grogerson-Gilson-Stead method showed that the total blood and plasma volumes tend to increase during gestation, reaching a maximum about the ninth lunar month, and returning to the average normal level postpartum.

Dr. Mandel E. Cohen spoke on the velocity of blood flow in normal and abnormal pregnant women. Arm to carotid and crude pulmonary circulation times were studied in a group of normal pregnant women and in pregnant women with heart disease. The values all ranged within the limits of normal nonpregnant individuals. The curve however of the average value for each month of pregnancy showed in both the cardiacs and the normals decrease in circulation time to the fifth month of pregnancy, an increase in the tenth month, a decrease immediately postpartum and then a gradual return to normal. In general, the cardiac values were greater than the normals. The curve of the mean circulation times was seen to correlate in general with that of viscosity and hemoglobin in these patients and to correspond to the cardiac output curve of other observers. No correlation was found between circulation time and pulse vital capacity, venous pressure, arterial pressure or costal angle. The circulation time tests were of no clinical value.

Venous pressure determinations done by the direct method of Moritz and von Tabora were reported on a series of eighty-five pregnant women (thirty-one normals, twenty-one compensated car-

diacs, fourteen decompensated cardiacs and nineteen "toxemics") by Dr. K. J. Thomson. With but one exception, a hypertensive cardiac with toxemia, and congestive heart failure, all of the venous pressure readings were below the upper limit of normal, i.e., 12.0 cm. of water. There was no essential change in venous pressure as pregnancy progressed and none after delivery. The average venous pressure for the normals, the compensated cardiacs and the decompensated cardiacs was in the vicinity of 7.0 cm. of water. The data on the "toxic" group were considered insufficient to warrant conclusions, but from the studies thus far there appeared to be no essential difference between them and the normals. Venous pressure determinations had proved to be not of practical value in the management of the pregnant cardiacs studied.

Dr. Thomson also reported a study of the vital capacity on seventy-six pregnant women (thirty-seven normals, thirty compensated cardiacs and nine decompensated cardiacs). In normal pregnant women the vital capacity is not decreased as pregnancy progresses and probably actually increases or remains essentially unchanged. In thirty of the thirty-seven normal cases studied the vital capacity was the same or higher antepartum than postpartum. The same changes though usually less marked, were observed in the group of compensated cardiacs but the average values in them were below those in the normal group. The average vital capacity in the normal group falls within the normal nonpregnant range, the average in the compensated cardiacs falls below the normal nonpregnant range. Three cases are presented who developed cardiac decompensation while being followed at monthly intervals with vital capacity determinations. These patients showed a drop in vital capacity before the onset of clinical heart failure of 20-25 per cent as contrasted with the maximum drop in a normal pregnant woman of 8 per cent and in a compensated cardiac of 7 per cent. The changes in vital capacity in cardiac decompensation in pregnancy are identical with those observed in nonpregnant cardiacs when decompensate. It is concluded that accurate vital capacity determinations made at frequent intervals during pregnancy on the pregnant cardiac may serve as a guide in predicting and diagnosing early heart failure before it is apparent clinically.

The papers of Drs. Cohen and Thomson were the subject of interesting discussion by Dr. C. Sidney Burwell and Dr. Soma Weiss.

Dr. Harold M. Teel presented a series of cases in which severe nonconvulsive toxemia of pregnancy was complicated with sudden seizures of dyspnea accompanied by acute pulmonary edema. The attacks closely resembled severe cardiac asthma. Past histories following studies and an autopsy indicated that these seizures in some instances complicated simple acute preëclampsia, without antecedent hypertension, valvular heart disease or chronic nephritis. The suggestion is made that the mechanism of acute pulmonary edema in eclampsia may be similar to that in these cases of preëclampsia.

Because of lack of time, two papers on the program were read only by title. These were "Observations on Lead V of the Electrocardiogram in Pregnancy" by Dr. K. J. Thomson and "Causes of Death of Cardiacs in Pregnancy" by Dr. Burton E. Hamilton.

FAULKNER HOSPITAL CLINICAL MEETING

The regular monthly clinical meeting was held at the Faulkner Hospital on Thursday afternoon, April 2.

Of the two cases which were presented for clinical pathological discussion, one was that of a woman, forty-nine years of age, who had used alcohol freely for some years and who had had two cesarian sections and one uterine suspension. The clinical picture was typical of intestinal obstruction and as so often happens, the condition was aggravated by increased amounts of cathartics having been taken by the patient without seeking medical advice. At the autopsy, there was evidence of alcoholic cirrhosis of the liver in the early stages and an intestinal obstruction caused by an adhesive band from the uterus complicated by a volvulus. At the time of the operation general peritonitis was present.

The other case was that of a boy, fifteen years of age, who died of sepsis associated with a streptococcus infection of the larynx and pharynx. The autopsy showed that the death was due to toxins and not to mechanical obstruction, which was feared at one time. For comparison with this specimen of the larynx showing a marked edema and infiltration, there was shown again the specimen of the larynx from the case of laryngeal diphtheria which was reported the preceding month making a very instructive pair of specimens.

Following the presentation of these two cases, Dr. Henry C. Marble showed the final result on two cases which he had presented at one of the meetings two years ago. The first was a boy who had an acute infection in the hip which had been drained. The interesting feature in the case was the marked ability of the young man to adapt himself to a hip joint which was absolutely fixed.

The other case was that of a boy who had had a skin graft from the abdominal wall to the palm of his hand. Although the palm of his hand is now covered with skin which has hair follicles in it the result is very satisfactory. The interesting point is the fact that sensation is present in this large skin graft. Just how the nerves regenerate is one of the interesting features of this type of grafting.

Dr. Marble then presented a case in which he had reconstructed the cut tendons of the hand which had become infected with marked retraction of the ends of the severed tendons.

Finally Dr. Marble emphasized the importance of having patients come to a hospital preferably forty-eight hours before an operation. The Faulkner Hospital has tried to stimulate its surgeons to follow this procedure with only moderate success with some. Dr. Marble feels that the length of stay in

the hospital is not increased by this procedure, and that complications are markedly diminished. He said that the insurance companies in his experience were glad to cooperate in this procedure so far as paying the bills of the patients is concerned.

Dr. Frederic J. Cotton then presented a series of cases in which ankles had been reconstructed following fractures which had healed with marked deformity. If a cartilage persists on the surface of the astragalus a new ankle joint can be produced which is exceedingly satisfactory.

He showed some cases in which the diagnosis of subacromial bursitis had been made, but in which he thought the pain on certain motions was probably due to the prominent greater tuberosity of the humerus. In several of these cases he had removed the prominent greater tuberosity subperiosteally with favorable results so far. The cases have not gone over a long enough period for him to speak positively about the final results.

He then showed x-ray pictures and described the operation of nailing the fragments together in a fractured hip. Apparently this operation does not produce shock. It saves time for the patient and allows motion in bed, and therefore, is a distinct improvement in the handling of fractured hips which, in elderly people, are so apt to result in a fatality from the prolonged and forced rest in bed.

He then, with Dr. Gordon M. Morrison, showed a series of x-rays of foreign bodies in the knees, usually spoken of as osteochondritis dissecans. They called attention to the fact that just what produces this condition is not always known, but they feel sure that one type is due to trauma, and another type is due to an overgrowth of bone around the edge of the cartilage which eventually breaks off and becomes a foreign body. Usually this can be removed by approaching the joint from the front, but they showed one case in which it had become necessary to approach the joint posteriorly. This had been done and the foreign body had been removed by this route successfully.

NEW ENGLAND SOCIETY OF PSYCHIATRY

The annual meeting of the New England Society of Psychiatry was held at the Gardner State Hospital on April 22, 1936. About 175 members of the representative New England States were present. Following a luncheon, served through the courtesy of the hospital, the business meeting was called to order by the president, Dr. Horace G. Ripley, of Vermont. The following physicians were elected to active membership: Maudie M. Burns, M.D., of Middletown, Conn.; Drs. Edwin M. Cole and Merrill Moore of Boston, Mass.; Dr. Salvador Jacobs of Danvers, Mass.; Dr. William J. Johnson, of Wientham, Mass.; Dr. Fernand Longpré of Northampton, Mass.; and Dr. Hosea W. McAdoo of Arlington Heights, Mass.

Officers for the coming year were nominated as follows: President, Dr. Winfred Overholser, Commissioner of Massachusetts Department of Mental

Diseases, Boston Mass. vice-president Dr Chester Waterman, Superintendent Connecticut State Hospital Norwich, Conn. secretary treasurer Dr Harlan L. Paine Superintendent of Grafton State Hospital North Grafton Mass. (retired) councilors Dr Arthur P. Nyers Superintendent of the State Hospital for Mental Diseases Howard Rhode Island and Dr Roderick B. Dexter Superintendent of the Foxboro State Hospital Foxboro Mass.

Announcement of the winners of annual awards for the best papers embodying research in psychiatry completed during the year 1935 was made and awarded as follows: Dr Benjamin Cohen for his paper "Repression and Communicability in Catatonie Stupor" (Staff Grafton State Hospital) Tamara Dembo and Eugenia Henfmann of Worcester State Hospital for their paper entitled "The Patient's Psychological Situation upon Admission to a Mental Hospital and Dr Benjamin Simon Worcester State Hospital and Philip Solomon Boston Psychopathic Hospital for their paper "Multiple Sclerosis".

Dr Abraham Myerson of Boston Mass. was the principal speaker and his subject was "The Neuroses".

HARLAN L. PAINE, M.D., Secretary

SUFFOLK DISTRICT MEDICAL SOCIETY

The Suffolk District Medical Society met March 13 1936, at the Boston Medical Library with Dr C. Wesselschoet presiding. Dr David B. Dill presented the first paper of the evening on the topic "The Laboratory Study of Fatigue". He pointed out that no exact definition of "fatigue" could be given. It involves some sort of upset of equilibrium and physical exertion does not necessarily precede its onset, for as is well known, fatigue may occur when an individual is sitting quietly in a comfortable chair or lying in bed. The rate of onset of fatigue is quite variable as is illustrated by its relatively slow development in the participants of a Marathon as compared with its rapid appearance in men competing in a quarter mile race. One of the changes involved in fatigue is the mobilization and utilization of fuel: first the readily available carbohydrate and subsequently fat. Little is known about the processes involved in the utilization of fat for energy purposes, although it is recognized that the ability of females to do so is much less than that of males: the former developing ketosis after a short period of starvation much more easily than the latter. There is also a great species difference in the ability to utilize fats for energy as is exemplified in dogs, in which animals it has been demonstrated that there is no evidence of acidosis in spite of a loss of 10 per cent of the body weight during prolonged exertion.

In extremely severe exertion the fat cannot be mobilized quickly enough to supply the needed energy and after the exhaustion of available carbohydrate extreme fatigue ensues. It has been shown that administration of glucose by mouth in dogs

performing severe physical exercise practically doubles the length of time that they are able to work before the onset of extreme fatigue. Dr Dill has confirmed these findings in human beings finding that the energy derived from carbohydrate falls progressively during prolonged exertion and that administration of carbohydrate food enables individuals to work longer without fatigue. Injections of adrenalin also served to provide more available glucose for the body's use and caused better utilization of carbohydrates. Following this effect there was no compensatory drop in the respiratory quotient indicating that the secretory activity of the adrenals is of marked importance in the body's resistance of fatigue.

During exercise there is an accumulation of lactic acid in the blood stream but the amount of this substance present in the blood is not an indication of the degree of the body's fatigue. It has been found that recovery from fatigue occurs in two phases: the first, of short duration during which there is only slight decrease in the blood lactic acid, and the second, of long duration with a slow disappearance of lactic acid. Partial recovery from a brief period of anaerobic activity may occur in as short a time as five or six minutes and the individual may again be able to perform work, although elevated levels of lactic acid may persist in the blood for an hour or longer. It is known that the immediate energy for muscular activity comes from the breakdown of phosphocreatin and that this product can be re-synthesized by use of the energy liberated in the formation of lactic acid, from muscle glycogen. It is probable that the first phase of recovery consists in the rebuilding of phosphocreatin at the expense of the formation of more lactic acid and that the second phase represents the more gradual rebuilding of lactic acid into glycogen. It is probable that the physical fitness of an individual is indicated by the rate of accumulation of lactic acid in the blood stream.

After strenuous exercise the acidity of the blood as measured by its pH is markedly increased but due to the rapid elimination of the excess carbonic acid through the lungs this acidity quickly returns to normal after cessation of the exertion.

The acceleration of the heart rate as a result of exercise is much more marked in individuals in poor physical condition than it is in those in good condition. It has also been found that the heart rate is accelerated to a greater degree when a certain amount of work is done in a hot environmental temperature than in a cold atmosphere. Prevention of evaporation of perspiration from the skin causes an extreme acceleration of heart rate in response to bodily activity and causes fatigue to develop much more rapidly than occurs if free evaporation of bodily moisture is allowed.

Dr Arlie V. Bock spoke on "The Clinical Aspects of Fatigue." He emphasized the fact that certain individuals fall into fatigue because of the lack of a rational basis of living. Some of their symptoms of fatigue may be accounted for by an irritable

BOOK REVIEWS

Lactobacillus Acidophilus and Its Therapeutic Application Leo F Rettger, Maurice N Levy, Louis Weinstein and James E Weiss 203 pp New Haven Yale University Press \$2.50

In his book, Rettger and his collaborators present a fairly complete monograph on the subject. For the average medical reader there is little of practical interest that could not have been said in a very few pages. The first chapters of the book are of interest only to the bacteriologist and are controversial in nature regarding the identity of the acidophilus organisms.

In subsequent chapters, therapy is considered in relation to simple constipation, constipation and biliary tract disease, 'mucous colitis', and idiopathic ulcerative colitis. These four groups of disturbances are discussed in more or less detail with a small number of illustrative case histories. So far as the discussion of constipation is concerned, it is an excellent one but it is very curious that no mention is made of one of the most important causes of constipation, namely, failure to establish a bowel habit in otherwise normal patients. The results obtained in this group of patients with simple constipation would seem to be satisfactory in many instances and the patients were followed over a sufficient number of months, in some instances as many as twelve to eighteen months, so that the conclusions seem justified. In the consideration of the treatment of constipation in patients with biliary tract disease one finds it difficult to accept the conclusions that the biliary tract symptoms have been relieved by the use of acidophilus cultures. Such symptoms are so frequently difficult of determination and the case histories offer so little evidence of proof in this matter that it hardly seems justifiable to draw conclusions from the few case histories given. So-called mucous colitis is well discussed. A few case reports are given suggesting very strongly that adequate acidophilus therapy may be of benefit in this group. The authors obviously have an adequate conception of the condition inasmuch as they also insist upon proper treatment of the individual who has the irritable colon. The treatment of a few cases of idiopathic ulcerative colitis is discussed and here again there seems to be some benefit from prolonged acidophilus therapy. One can agree heartily with the authors, however, that it is unwise to accept without question the permanency of favorable results from this form of treatment in view of the characteristic tendency of the disease to have relapses and remissions.

One important point that the authors make is that, when acidophilus therapy is to be attempted, the cultures should be of such a standard that they are viable and the organisms are sufficiently concentrated to produce results. In addition, they insist upon the necessity of prolonged treatment before expecting anything like lasting results.

For practitioners the book is altogether too tech-

nical for general interest and for the average reader it could have been made much shorter by avoiding many controversial points. The clinical results are of interest but do not cover a sufficient number of cases to be absolutely convincing. The book should be of interest to those who are particularly concerned in this phase of therapy and it is evident that the authors have attempted an honest and thorough study of the value of this particular form of treatment.

Emotions and Bodily Changes. A survey of literature on psychosomatic interrelationships 1910-1933 H Flanders Dunbar 595 pp New York Columbia University Press \$5.00

As the title suggests this extensive survey of nearly six hundred pages deals with the vast and rapidly growing bibliography upon the interrelationship of mind and body. It is well conceived and well executed, and also well indexed as to subjects and authors.

This book adds weighty and important evidence that the old argument over somatic or psychic must be replaced by the present day attitude, *how much* somatic and *how much* psychic, as the constant interrelationship between the two cannot be denied.

Puerperal Gynecology J L Bubis 199 pp Baltimore William Wood & Company \$3.50

In this book Dr Bubis advocates delayed or immediate repair of old as well as of new birth injuries after delivery. There can be no question of the advantage and advisability of repairing fresh injuries. There can also be no question as to the desirability of having these repairs performed by an obstetrician who is at the same time a trained gynecologic surgeon. When it comes to the radical advocacy of extensive repairs of old lesions, such as operations for cystocele, amputation of the cervix, hemorrhoidectomy, etc., one may well hesitate to follow him. Bubis's argument in favor of his procedure is chiefly an economic one. That being the case it is imperative that he be able to show that the procedures which he employs are free from risk. His figures, which for the most part are from statistics collected prior to 1930, do not seem to substantiate this claim. Out of 1353 cases, whose records are classified in considerable detail, forty-six per cent showed some complication, sixteen per cent were admittedly due to the gynoplastic repairs and ten per cent were not so caused, the balance, or nineteen per cent showed "postoperative reactions," a term which is not accurately defined. There were four deaths, at least two of which could be directly attributed to the operative interference. It does not seem to the reviewer that the author's case has been proved. Adding the morbidity of the obstetric work to the morbidity of secondary repairs to be done at a sufficient interval of time postpartum, the total would be far lower than that reported.

NUMBER 19

WHAT WE HAVE LEARNED FROM THE TOAD CONCERNING HYPOPHYSAL FUNCTIONS*

BY HERNANDO A. HOUSSEY, M.D.†

THERE are three reasons which justify the dedication of my first lecture to such a humble living creature as the toad (1) because more than twenty five years ago my first publication in *Physiology* was on the pituitary of amphibians, (2) because the toad is the species in which the largest number of functions related to the pituitary has been found and studied, and (3) because hormonal actions are not species specific, but have a fundamental similarity throughout the vertebrate series.

To these reasons others may be added which justify the use of this animal, as I can well appreciate after experimenting on more than 15,000 toads of the species *Bufo arenarum* Hensell.† Such are, its abundance and cheapness, its resistance to trauma, the facility of operative techniques, the great number and clarity of the symptoms of pituitary insufficiency, the rapidity and intensity of the reaction to implantation of any of the lobes of the pituitary and the possibility of making experiments and obtaining proofs more easily and in larger numbers than with any other animal. For these reasons we have preferred to employ the toad rather than the frog, *Leptodactylus ocellatus* (L.) Gir common to our country, which we studied in 1910, 1916 and in 1924 but which is much less resistant.‡

Let us remember that the amphibian pituitary consists of four parts 15 16 17 18 (Figs. 1 and 2)

(1) The principal lobe (distal chromophile or *pars glandularis*) which corresponds to the anterior lobe of the mammalian pituitary but which lies posteriorly in amphibians.

(2) Intermediate part (proximal or chromophile, *pars intermedia*)

(3) Neural part (nervous or neurohypophysis, *pars nervosa*)

(4) Tuberal part (*pars tuberalis*) which however we have not been able to identify in *Bufo arenarum* Hensell.

Durham Lecture delivered November 23 1925 at the Harvard Medical School.

In the first works we published we called this toad *Bufo marinus* but since 1929 we have corrected this zoological error.

We have observed with only slight differences symptoms generally analogous in *Leptodactylus ocellatus* (L.) Gir (Houssey and Houssay and Ungar 1934) *Bufo marinus* *Bufo paracnemidus* *Bufo dorsalis* *Craugastor ornata* *Hyla* sp. etc.

Houssey, Bernardo A.—Professor of Physiology Faculty of Medical Sciences, University of Buenos Aires 1915. For record and address of author see "This Week's Issue" page 246.

The intermediate and neural parts are closely united forming a lobe which is equivalent to the posterior lobe in mammals, although here it is anterior and may be called the *intermediate-neural*.

lobe The principal lobe can readily be extirpated whole, if afterwards the neuro-intermediate part is extirpated the hypophysectomy is total. The pituitary is situated caudo ventral to the infundibular lobe of the brain. The latter is a prolongation of the hypothalamus behind the optic chiasm and may be designated as the *infundibulotuberal region*.

The functions of the pituitary and of the tuberal region are studied by producing lesions or by implantations. The following techniques were systematically applied to the study of each function: (1) Trans-sphenoidal extirpation of the principal lobe only or of the entire pituitary 15 17 18 (2) Puncture with a needle or cauterization of the infundibulotuberal region.

either posterior or anterior to the optic chiasm* For cauterization a hot needle or the galvanocautery was used (3) Subcutaneous implantation of the entire toad pituitary, or of the principal and neuro-intermediate lobes separately

*The supra optic nucleus is situated deeply in front of the chiasm. It is fairly large and sends fibres to the pituitary (Greving 1928 Scharrer 1934 Carrillo, unpublished)

(4) Injection, separately, of extracts of the same lobes or of extracts of the anterior, neural or intermediate parts of mammalian or other vertebrate pituitaries

The symptoms which can be observed in the toad are referable to the following systems and processes: the skin, the genitalia, the circulatory system, the endocrine system, the neuromuscular system, gaseous exchange, nitrogen, carbohydrate and water metabolism, sensitivity to poisons, rate of mortality, etc. These have all been studied in our Institute and the results published in more than eighty papers*

*For previously published summaries of this work see references 25 35 37

The syndromes which have so far been described may be classified in four large groups according to their etiology (1) pituitary insufficiency, (2) pituitary hyperactivity, (3) infundibulotuberal syndromes, (4) infundibulohypophyseal syndromes.

PITUITARY INSUFFICIENCY

Insufficiency of the intermedioneural lobe

These symptoms become manifest within a few minutes or hours after total hypophysectomy. They do not occur if only the principal lobe is extirpated or with lesions of the Lobus infundibularis of the brain. The implantation or in-

33 per cent. It is rare and transient after tubal lesions. It can be arrested by injection of toad neuro-intermediate lobe or mammalian posterior lobe. The polyuria is of renal origin as it is not observed in toads unless they are immersed in water. Absorption of water by the skin⁷⁷ is performed at the same rate in nephrectomized toads and in those with ureters tied, whether they be hypophysectomized or normal controls. The recent experiments of Pasqualini have induced the writer to abandon the belief that the polyuria is a tubal symptom (c) *Fall in arterial pressure*⁷⁸ If the whole gland is removed this is rapid, intense and pro-

A

FIG. 3.

B

jection of either lobe will correct the disorders, but the neuro-intermediate lobe is the most active. The symptoms are

(a) *Cutaneous pallor*^{72, 73} due to contraction of the melanophores and expansion of the xanthophores. (Fig. 3) Thus pallor disappears on injection of extracts of the toad's intermedioneural lobe, or of extracts of the neural or of the intermediate parts of the mammalian pituitary. Of the last two the second is the more active. Extracts of the anterior lobe of the mammal, or of the principal lobe of the toad can produce darkening but are much less active and in the case of the toad extract seven times less potent than the neuro-intermediate lobe extract.⁷⁴

(b) *Polyuria*^{75, 76} This is intense and persistent in 70 per cent of toads after total hypophysectomy. After removal of the principal lobe alone it is less frequent, occurring in only

progressive. The fall begins within a few hours after operation and continues progressively from 30 mm of mercury to 24 mm. in a week and 17 mm in a month. Extirpation of the principal lobe alone does not cause this hypotension, although a slight fall of blood pressure appears later on when asthenia develops. There is no fall of blood pressure with lesions limited to the infundibulotuberal region. The injection of neuro-intermediate or of glandular lobe causes the blood pressure to rise the glandular lobe being less active.^{77, 78, 79} Although the total amount of blood is almost the same in hypophysectomized toads as in the normal controls less can be obtained by bleeding the former because it remains in the blood vessels. The circulating blood has fewer red blood corpuscles (Varela and Sellares, 1934, Parodi unpublished), and there is leucopenia with a decrease of the polymorphonuclear cells and of the monocytes (Varela and Sellares 1934).

(d) *Dilatation of the capillaries*^{80, 81} This can

⁷⁷Allen has shown that only the pars intermedia is active in other species of amphibia.

always be observed in the skin when the entire pituitary is extirpated but it is less constant and intense when the principal lobe alone is removed or the *Lobus infundibularis* of the brain injured

Insufficiency of the principal lobe

Following the extirpation of the principal lobe only (which corresponds to the anterior pituitary of mammals) characteristic symptoms slowly develop. These symptoms appear slightly more rapidly after removal of the whole pituitary, but they do not occur after simple lesions of the *Lobus infundibularis*. The morphogenetic and sexual symptoms are compensated only by administration of the principal lobe, the metabolic and general symptoms by both lobes, though the principal lobe is always more active

I Morphogenetic and endocrine regulatory functions

(e) Retardation and cessation of growth have been described in other amphibians by Allen (1916), Smith and others, but we have not studied this point in *Bufo arenarum* et al

(f) The thyroid epithelium shows signs of atrophy^{58 59}. It becomes flattened, the vesicles very large and the colloid homogeneous and readily stainable (see fig 11)

(g) We have not been able to confirm with certainty the atrophy of the adrenal cortex seen by Smith (1920) in tadpoles, the medullary part is not altered and its adrenalin content is not lowered⁴⁷

II Sexual and reproductive functions

(h) Testicular atrophy^{13 18 30 37 40 41}. The testes weigh less than in the controls, and there is atrophy of the seminiferous epithelium and interstitial tissue. There is no compensatory hypertrophy after subtotal castration²⁰

FIG 4
Chart showing the effect of removal of the principal lobe of the hypophysis (broken and solid lines) in the toad on the concentration of blood sugar liver and muscle glycogen as compared with normal controls (dotted lines)

(i) Atrophy of Bidder's organ^{41 43}, occurs both in castrated animals and in those with intact sex glands, and there is no compensatory hypertrophy in the castrates

FIG 5
Chart showing decrease in the total phosphorus phosphocreatine phosphorus and inorganic phosphorus in the muscles of the toad following removal of the principal lobe of the hypophysis

(j) Ovulation* fails to occur even in the mating season and with the normal sexual stimulation, namely the sexual embrace

III Metabolic functions

(k) The consumption of oxygen does not diminish until asthenia is marked

(l) The concentration of blood sugar and the glycogen content of the liver^{27 28 29} and heart³⁰ are progressively lowered. Later the muscle glycogen also decreases^{27 28 29} (Fig 4.)

(m) Phosphocreatine and glutathione in muscle^{30 32} (figs. 5 and 6) and the glutathione of

FIG 5.

Chart showing the decrease in glutathione in the muscle of the toad following removal of the principal lobe of the hypophysis and its restitution by injection of extract of bovine glandular (anterior) lobe

See reference 26. Further proof of this, however is necessary.

*Data obtained by Artundo published by Housay and Gust.

the liver are diminished. The basal lactic acid³¹ is normal, but during muscular activity it increases less than in the controls.

(n) The hyperglycemia following injection of adrenalin or morphine are less marked than in the controls.³²

(o) Pancreatic diabetes, which is intense in the controls is less severe and may even fail to appear.^{3 7 8 29 30 31 33}

(p) Phlorhizin glycosuria is less marked and may not occur.¹¹ However, hypoglycemia and convulsions develop and there is a high mortality.

(q) Sensitivity to the hypoglycemic and toxic actions of insulin^{34 35} is marked, whereas sensitivity to other toxins is not changed.¹⁷

Orlans³⁶ has observed the same phenomenon in the fish *Musculus costalis* and Housay and Blasotti³⁷ in other amphibia and reptiles.

FIG 7

FIG 7

Figs. 7 A and B are untouched photographs showing the state of *Gallinula hypophyseotoma* in the toad after removal of the principal lobe of the hypophysis. A. The earliest symptom: inability to remain in the normal posture when laid upon its back. B. Typical posture at a later stage.

(r) Lowered elimination of *urinary nitrogen* during fasting has been observed. It may be 30 per cent less than in the controls⁶

IV *General symptoms, probably metabolic*

(s) There is great sensitivity to slight *operations* and *traumata*, and the mortality rate is high^{2 25 26 50 72}

(t) Marked *neuromuscular asthenia* appears, which is progressive and finally fatal^{9 14 15 16 17 18 24 25 35 36 76} (Fig 7) This commences fifteen to twenty-five days after operation, the first

symptom being the inability of the toad to turn over when placed on its back. Later there is slowness of movement and progressively increasing weakness. Convulsions occur in 5 to 10 per cent of the cases. The mortality is highest during the fourth to the seventh weeks, and very few animals live as long as three to five months. When the asthenia begins there is

A

B

C

D

FIG 8
Unretouched photographs showing the hyperkeratinization in hypophysectomized toads. A and B Dorsal and ventral views of normal toads (female). C and D Dorsal and ventral views of hypophysectomized toads (female).

diminished excitability of the sensory reflexes, but the chronaxie of the nerve and muscle continues unaltered.²⁰

(u) *Cutaneous hyperkeratinization* There is formation of a thick horny layer which is adherent to the skin.^{2, 13, 14, 15, 16, 25, 26, 27, 28} The skin becomes covered by a dark brown or bronze cuticle, due to an exaggerated production and a failure of normal desquamation of the horny layers.^{1, 2} (Figs. 8 and 9)

Symptoms j, m, n p q, appear immediately after operation, u in three to eight days and l t v and w in from fifteen to twenty five days. All these symptoms, particularly the metabolic and general ones, can be prevented or corrected by the implantation of the principal lobe of the toad or of mammalian anterior lobe.* The sexual modifications are only influenced by the toad pituitary and to a lesser extent by that of other amphibians †

FIG. 9
Microphotographs of the skin of a normal toad, A, as contrasted with that of a hypophysectomized toad B. Note the thick cuticle of the latter melanophores.

(v) The *cutaneous secretions* are greatly diminished.^{1, 2}

(w) There is slowing of the *heart*, decrease of its glycogen content and rise in its chronaxie.^{10, 20} After some time in a few of the toads the cardiomodulating action of the vagus is diminished, or may even be totally suppressed.^{20, 28}

Evidence for the central origin of the asthenia is furnished by the facts that the first indications of this syndrome are alterations of the postural reflexes and reflex excitability and also that there may be convulsions. Further the motor nerve and muscle excitability is not affected until later and then only slightly. The peripheral factor is less important.²⁸

PITUITARY HYPERACTIVITY

This is brought about by implantation of either lobe or by injection of toad pituitary extracts or extracts of mammalian pituitary. In general these symptoms are the opposite of those of pituitary insufficiency.

*The thyrotrophic function of the latter is doubtful and the sexual is absent in the toad.

†Although other amphibians respond to the sexual action of mammalian pituitary this toad is unaffected, a fact which up to now has remained without satisfactory explanation.

FIG. 10
Graphic representation of the increase in weight of toads injected with graded doses of dry bovine posterior lobe. Ordinate, percentage increase in weight. Abscissa, milligram of dry bovine posterior lobe injected.

Hyperactivity of the neuro-intermediate lobe

This occurs with administration of the neuro-intermediate lobe of the toad or of the posterior mammalian lobe

(a) There is *darkening of the skin*^{14 15 16 20 25 35 36 37 51 52 53 54 85} due to expansion of the melanophores, the principal lobe and the anterior mammalian lobe have a similar action which lasts a long time but is less intense

(b) *Oliguria* with or without increase of weight^{50 72} With small doses varying degrees of oliguria are produced, but with large doses there is complete anuria which lasts five to six hours Increase in weight occurs in the latter cases and may be considerable (fig 10), with interstitial, peritoneal and subcutaneous edema^{5 35 36 37 67 72}

(c) The *rise in blood pressure* is marked in hypophysectomized animals with initial low blood pressure, but less so in normal animals The neuro-intermediate (or mammalian posterior lobe) is more active than the principal lobe The blood of the normal toad when injected into hypophysectomized toads causes a higher rise in blood pressure than the blood of hypophysectomized toads similarly injected (Neubach, unpublished)

(d) *Contraction of the Capillaries*¹¹ of the skin may be produced by a large dose, if the vessels were previously dilated

Hyperactivity of the principal lobe

This can be produced by implantation of the glandular lobe, which is the only one that has morphogenetic effects and effects on other endocrine glands The metabolic and a few other general symptoms can also be obtained to a certain extent, but in a less marked degree, by implantation of the neuro-intermediate lobe

1 *Morphogenesis and regulation of endocrine glands*

(e) *Acceleration of growth* has been observed in the larval form of other Anura by Allen, Smith, etc., we have not studied it in *Bufo arenarum*

(f) *Hyperplasia and hyperactivity of the thyroid*^{58 59} are revealed by the state of the epithelium (Fig 11) The cells become high columnar in type and there is vacuolization and reabsorption of the colloid

(g) *Stimulation of the adrenals* has been seen by Smith in tadpoles, but has not been confirmed in this toad

2 *Sexual and reproductive functions*

(h) *Hypertrophy of the testes*^{23 35 36 40 41} occurs in normal and hypophysectomized animals The testes increase in weight, the seminal canals are dilated by fluid containing free spermatozoa, there is hypertrophy of the seminiferous epithelium and of the interstitial tissue

(Fig 12) The sexual embrace reflex appears out of season, even when the tuber is destroyed, and in immature animals precocious puberty takes place

(i) *Hypertrophy of Bidder's organ*^{41 43} occurs in normal and hypophysectomized animals, particularly in castrates It can be definitely stated that Bidder's organ cannot be transformed into ovarian tissue unless the pituitary is present (See II, 1, Atrophy of Bidder's organ)

(j) *Ovulation and expulsion of the ova*^{32 35 36 37 40 53 66} occur in one to three days Observations were made by us (loc cit) independently of those of Wolf This phenomenon also takes place in the absence of various organs* and of the larger part of the brain (See In fundibulohypophyseal symptoms)

3 *Metabolic functions*

The metabolic functions are only slightly affected in normal animals but much more so in the hypophysectomized

(k) The *respiratory metabolism* does not change

(l) There is *rise in blood sugar* and *hepatic glycogen*, also in *muscular*^{27 34 48} and *cardiac*^{10 70} glycogen

(m) The *hyperglycemia* produced by morphin and *adrenalin* is more pronounced³³

(n) There is a marked *increase in pancreatic diabetes*^{5 28 29 30 32 45} particularly in the hypophysectomized toads and in those with infundibulotuberal lesions In this reaction the liver plays an indispensable rôle (Campos and collaborators), but certain other viscera, namely the forebrain, the midbrain, the intermediate brain and the adrenals do not In toads with intact pancreas no diabetogenic activity can be obtained, even when forty lobes are implanted³¹

(o) *Phlorhizin glycosuria* is increased¹¹

(p) The *hypoglycemic* and the *toxic effects of insulin* are reduced both in normal and hypophysectomized animals^{49 50}

(q) Increased *elimination of nitrogen* occurs in the hypophysectomized toads²⁷

4 *General symptoms* (probably metabolic)

These can only be produced to a slight degree in normal animals, but they are very marked in the hypophysectomized

(r) *Operations are well tolerated*^{2 25 26 59 72} by the hypophysectomized toads

(s) *Asthemia* which follows hypophysectomy is prevented or cured^{2 9 24 35 73} The animals recover or, if treated early, maintain their agility and do not die Sometimes it is possible to effect a cure even after convulsions have set in

*The gonadotropic action of the principal lobe is not modified either in thyroidectomized or castrated animals^{42 44} There is also a gonadotropic action in fishes and reptiles²¹

(t) The formation of a horny cuticle¹⁰ by the hypophysectomized toads is prevented, or if already formed, this cuticle is shed. Thus the principal lobe of the pituitary may be said to regulate the shedding of the skin.

(u) Cutaneous secretion, which is scarce in the hypophysectomized toads, is restored to normality or its diminution may be prevented.

(v) It is possible to prevent or correct the bradycardia, the fall in cardiac glycogen, the decrease in cardiac chronaxie¹⁰ as well as the ineffectiveness of the vagus which follows hypophysectomy.

INFUNDIBULOTUBERAL (DIENCEPHALIC) SYMPTOMS

There is only one symptom* referable to lesions which are limited to the diencephalon. This is the sexual emigration^{26, 27} which occurs in a large number of male toads when the infundibulotuberal region is cauterized.

INFUNDIBULOHYPOPHYSIAL (DIENCEPHALIC) SYMPTOMS

If the *Lobus infundibularis* is injured see

Originally we thought ovulation, polyuria and the fall of a thick horny layer were diencephalic symptoms (see infundibulohypophyseal symptoms).

Anatomy and vascularization described by Houssay, L. and Sammartino.²⁸

Secondary alterations occur in the pituitary. First the circulation on its ventral surface stops and later a central infarct develops in the principal lobe (Figs 13 and 14). This reaches its maximum in seven days, lasts some eleven to seven teen days and finally the lobe regenerates in twenty five to thirty five days, the chromophobe cells appearing earlier than the chromophile cells.^{27, 28, 29, 30}

As a result there is an early stage of increased reabsorption of glandular products followed by a later stage of prolonged inhibition of the pituitary functions ‡.

The initial increase in reabsorption is characterized by

(a) Transient darkening of the skin^{16, 28, 29, 30} lasting one to three days which does not occur if the neuro-intermediate lobe is absent.

‡The same is observed in the dog (Houssay, Davis, etc.).

FIG. 13

- (10) Transverse retrolinfundibular artery

B—Following cauterization of the infundibular lobes and tuberculum cinereum

The lobus infundibularis the base of the mesencephalon and the anterior part of the crura cerebri are involved

(c) *Polyuria*^{35 36 37 38 72} which is transient and inconstant and is due to neuro-intermediate insufficiency

The functional inhibition of the principal lobe is characterized by

(d) *Thickening and adherence of the horny layer of the skin*^{1 2 14, 15 16 28 32 35 37 76} which is observed in 15 to 60 per cent of the cases and which may be corrected by administration of principal lobe extract

(e) *Inhibition of pancreatic or phlorhizum diabetes*,^{27 28 32} which is usually slightly less intense than in the hypophysectomized animals. When implanted these pituitaries have the usual diabetogenic activity, and their gonadotropic effect is only slightly diminished, but *in situ* they do not function normally

Apart from these outstanding symptoms others which are less marked can be observed. Among these may be mentioned asthenia, which is rare, occurring only in 10 to 15 per cent of the cases;²⁴ a slight flattening of the thyroid epithelium;²⁸ a slight but inconstant fall in blood sugar;⁴⁸ and a slightly irregular arterial blood pressure which may be above or below normal.^{17 39 69} The heart,⁷⁰ the testes,⁴¹ the hemoglobin content of the blood,⁷¹ and the liver glycogen^{48 49} are normal

PITUITARY HORMONES

Although the actual hormones have not been isolated, nevertheless on the basis of an analysis of the symptoms of insufficiency and hyperactivity and the effects of restitution, it can be considered probable that hormones, with actions as listed below, exist

The neuro-intermediate lobe possesses in larger proportion than does the principal lobe melanophore dilator, arteriole and capillary constrictor,^{50 72} oliguric, water metabolic^{50 72} and oxytocic⁶ actions, and in lesser degree than does the principal lobe a regulatory action on carbohydrate metabolism.^{5 7 23 29 30 32 45†}

The principal lobe alone^{2 76} possesses gonadotropic,^{2 9 24 25 35 36 40 41 43 76} thyrotropic,^{58 59} growth stimulatory and cutaneous actions. In common with the other lobe, but to a much greater degree, it possesses a regulatory action on carbohydrate metabolism^{5 7 23 29 30 32 45†} and to a lesser degree it acts on the melanophores, the small vessels, the excretion of urine and the metabolism of water

SUMMARY

In the toad the pituitary is a most important organ, as it controls functions which are necessary for the maintenance of the life of the in-

*Houssay, Glustl and Lascano-Gonzalez^{10 41} found the activity of the principal lobe to be on an average 0.001 International units per mg and 0.042 units per lobe that of the neuro-intermediate 0.41 units per mg and 0.95 units per lobe which is the same as that found in bovine posterior pituitary lobe (Houssay, Glustl and Lahille²⁰)

†Orlitz²⁸ has observed the same phenomenon in the fish *Mustelus canis* and Houssay and Blasotti²⁰ in other amphibia and reptiles

dividual and also controls sexual and reproductive activities which are necessary for the maintenance of the species. It is the central organ in the endocrine constellation, as it is necessary for the development and maintenance of the anatomical and functional integrity of the other internal secretory glands.

The neuro-intermediate lobe governs various functions

(1) It maintains the normal color of the skin (with its physiological and pharmacological changes) by preserving an adequate melanophore expansion. The secretion of this hormone is regulated reflexly, and is therefore under the control of the central nervous system.

(2) It preserves the tone of arterioles and capillaries, thus having an important influence in the maintenance of the arterial blood pressure.

(3) It regulates the water metabolism, first by its action on the kidneys and, secondly, on the skin and other tissues.

The principal lobe governs the following functions

(1) The development and maintenance of the thyroid and the gonads (including Bidder's organ). It also provides for their compensatory hypertrophy. An adrenotropic action has not been demonstrated in the adult toad.

(2) The occurrence of normal ovulation is due to a pituitary hypersecretion in the female which is reflexly stimulated by the sexual embrace.

(3) The development of the thyroid which permits the metamorphosis of the larva into the adult form.

(4) The regulation of the casting of the skin (with the formation and desquamation of the horny layer) and also the regulation of the cutaneous glandular secretions.

(5) The metabolic functions (carbohydrate metabolism, endogenous protein metabolism, etc.) These are so important, that the loss of pituitary control leads to a state of progressive asthenia causing death in three to eight weeks. The central nervous system is affected and later the heart, muscles, etc.

Injury of the tuber cinereum produces secondary lesions in the pituitary with an initial glandular reabsorption and later a more or less marked state of pituitary insufficiency.

It is evident that many of these functions of the pituitary either cannot be seen in mammals or will have less importance than in the toad. I have found many functions in the latter which only later were seen in the mammal. For this reason I have studied each function primarily in the toad and simultaneously or subsequently in the more complex animals, and so have been able to understand its significance more readily. No student of the hypophysis can ignore the val-

uable results obtained by studying its functions in the toad, and all will feel grateful to this low species for the many secrets it has revealed on such an important organ.

A STUDY OF THE USE OF CORAMINE IN DEALING WITH THE EFFECTS OF BARBITURIC ACID DERIVATIVES*

BY PURCELL G SCHUBE, M D †

THE drugs of the barbituric acid series, since their introduction to the medical profession, have been widely used in order to induce states of unconsciousness ranging from simple sleep from which it is easy to rouse an individual to what amounts to a barbituric acid coma from which no amount of urging, chemical or physical, will produce consciousness until the effect of the drug has worn off. It is only to be expected that with such wide use of these drugs, by both skilled and unskilled persons, a certain number of bad reactions will occur. But unfortunately some of these bad reactions become worse, and individuals die.

Furthermore, since it has been possible to buy these drugs for a small sum at any drug counter, the layman becoming depressed or otherwise wishing to die, has by their use increased the number of near-deaths and deaths quite considerably. And there are sufficient reports in the existing literature relative to these fatalities to quiet any skeptic—to make him wish to have

at hand a ready and safe counteracting drug should it fall to his lot to have to treat such a case of poisoning.

It is the belief of the writer that coramine is such a counteractant, such belief being the outcome of the work presented in this paper and the work which has been conducted for so many years by European workers and recently by a very few Americans, on the effect of coramine on hypnotics, narcotics and anesthetics.

One of the first pieces of work in this respect pointed to its possible value, for in 1892 Koppen¹ while studying the then relatively new drug, coramyrin, reported that it was of value in the counteraction of narcosis. In 1924 Uhlmann² confirmed these findings, stating that coramine stimulated the centers of the medulla, respiration especially being affected, i.e., increased. In addition he found that this drug produced a rise in the blood pressure and increased the cardiac excursions. In 1925 Guth³ demonstrated increased blood flow due to coramine in patients under the influence of general anesthesia. In 1926 Ashe⁴ at this time stated that coramine improved not only the circulation of animals under depressant drugs but also the

*From the Psychiatric Clinic Boston State Hospital Boston Mass

†Schube Purcell G—Physician in Charge Psychiatric Clinic Boston State Hospital. For record and address of author see This Week's Issue page 946

respiration, concluding that it was of definite value in this respect. In 1928 Bürgi and Gordonoff⁷ found that coramine rendered the heart more resistant to the action of depressant drugs. In 1928 Schübel and Gehlen,⁸ in 1929 Helaers⁹ in 1931 Kilban,⁸ Mörl,⁹ and Domang¹⁰ in 1932 Kennedy,¹¹ Fischmann,¹² Glaeser,¹⁴ and Altman,¹⁴ in 1933 Kilhan,¹³ Buzzo and Bertani,¹⁵ Reese¹⁷ and Wood¹⁶ in 1934 Ervenich,¹⁸ Takabe,¹⁹ Schwoerer,²¹ in 1935 Gillensvärd and Bazzo and Bertani,²⁴ and in 1936 Levi and Krinsky²⁴ and Eversole,²³ to mention a few all confirmed the value of coramine in relieving depressed respiration or unconscious states due to hypnotics, narcotics or anesthetics.

And so the reports on the value of this drug as a tool in the counteraction of the effects produced by narcotics, hypnotics and anesthetics have gradually accumulated all pointing with more or less accuracy to the positive value of coramine in cases where the respiration is depressed and unconsciousness is present and where it is advantageous to terminate the action of the depressant drug with as little delay as possible. It is the purpose of this paper to present a planned study on the actual value of coramine in the counteraction of the unconscious states produced in human beings by the administration of certain barbituric acid derivatives.

METHOD

All of the individuals in this study were males. Their ages ranged from sixteen to fifty-five years. All were mentally ill, the type of illness ranging throughout the psychotic scale. It was not felt that these individuals would produce results other than what might be expected of individuals with apparently normal personality reactions. Physically they were normal.

Each person was given the specified drug and then placed in bed. When he was asleep attempts were made to rouse him by moderate shaking. If this was unsuccessful pinpricking was resorted to. Only those individuals were used who were sufficiently under the influence of the prescribed barbiturate not to rouse from their sleep as a result of the above stimulation.

As soon as the person was definitely asleep his blood pressure, pulse, respiration and clinical state were noted and then 5 cc. of coramine was administered intravenously. The patient was watched in this manner for ten minutes and if consciousness had not been restored at the end of that time, 5 cc. of coramine was administered every ten minutes until he did rouse. The coramine was given intravenously in every instance.

The effect of the coramine on patients having received a barbituric acid derivative was examined a total of 84 times. The controls received

the barbiturate but no coramine. There was one control for each type of barbiturate used.

RESULTS

The Efficacy of Coramine in Relieving the Symptoms Produced by the Barbituric Acid Derivatives

A Sodium amytal

- 1 Twenty-four individuals each received 12 grams of sodium amytal by mouth. Of these eighteen were relieved of their symptoms by 5 cc. of coramine, four by 10 cc. and two by 15 cc.
- 2 Twelve individuals each received 7½ grams of sodium amytal intravenously. Of these eight were relieved of their symptoms by 5 cc. of coramine and four by 10 cc.

B Luminal

- 3 Twelve individuals each received 6 grams of luminal by mouth. Each was relieved of his symptoms by 5 cc. of coramine.
- 4 Twelve individuals each received 6 grams of sodium luminal intravenously. Each was relieved of his symptoms by 5 cc. of coramine.

C Sodium Oral

- 5 Ten individuals received 9 grams of sodium oral by mouth. Each was relieved of his symptoms by 5 cc. of coramine.

D Nembutal

- 6 Five individuals received 3 grams of nembutal by mouth. Each was relieved of his symptoms by 5 cc. of coramine.
- 7 Six individuals received 7½ grams of nembutal intravenously. Each was relieved of his symptoms by 10 cc. of coramine.
- 8 Three individuals received 15 grams of nembutal per rectum. Two were relieved of their symptoms by 15 cc. of coramine and one by 20 cc.

The Effects of the Coramine as Observed During the Study

In each individual who had received a barbituric acid derivative the primary and important factor relieved was the state of unconsciousness. In each instance this state was abolished some persons having to receive more coramine than others in order to achieve this result. The pulse rate and volume in no individual was altered appreciably by the coramine. Likewise the blood pressure was not altered appreciably regardless of whether arteriosclerosis was present or absent, and irrespective of the presence of normal low or high blood pressure. In each person the respira-

tions were increased, not only in rate but also in depth. The rate was increased from two to ten per minute. The depth was increased from just slight increases to increases which, in two cases not a part of this paper but who had taken almost 100 grains of luminal and who had received 80 and 85 cc of coramine, were profound and noisy and could be distinctly heard and counted at least thirty feet away. The skin over the face was occasionally flushed. No sweating was observed. In twenty-one cases the administration of coramine in 5 and 10 cc doses was definitely followed by hiccoughs which lasted from five to fifteen minutes. In five cases after 10 cc of coramine there was vomiting which was projectile, lasting a few minutes and then subsiding. In no individual was there any alteration in the emotional or intellectual state as evidenced either by questioning or by observation of physical activity.

The After-Effects of Coramine

Other than the relief of the symptoms produced by the administration of barbituric acid derivatives, no after-effects of any type were noted.

Controls

For each barbituric acid derivative one control individual was used. He was given the same dosage of the barbiturate as the individuals receiving, in addition, the coramine. In every instance the control individuals remained unconscious for hours longer than the persons receiving coramine, who were unconscious a matter of minutes.

DISCUSSION

With the barbituric acid derivatives having such widespread use by the medical profession and such careless and deliberately destructive use by the laymen, it is imperative that there be available some drug which is able to counteract the effects of these derivatives, some drug which is safe and in which the safety is wide of margin. Furthermore, inasmuch as there is occasionally a bad reaction from a very small dose of these barbiturates it is even more imperative that a counteracting drug should be available which is rapid in action. The results of this study and of the studies which have preceded it would tend to establish coramine as safe, and as a drug relatively certain to counteract rapidly the symptoms of drugs of the barbituric acid series. The fact that in this study there were encountered no failures is quite important, for it is this type of result which is desired in the use of an "antidote" for any drug whose reaction may become undesirable.

This study, of course, cannot claim results of value in instances other than those described, but from the results reported it would most certainly be inferred that coramine would be of

value in counteracting the effects of a wide range of barbiturates with a wide range of dosages. Further studies, it is hoped, will clarify this point and give greater insight into the ability of coramine to neutralize larger doses of the barbiturates in man. Moreover, from this study, it is impossible to predict the length of time which may lapse between the administration of the barbiturate and the administration of the coramine, and the latter still work effectively. It can only be said that from experience in this respect with the two cases referred to, it was learned that with exceptionally large doses of luminal, i.e., about 100 grains, a lapse of sixteen hours between the taking of the barbiturate and the administration of the coramine was too long an interval for resuscitation to take place.

The dosage of coramine could not be standardized in this study, because it appeared that there was a definite individual ability or disability of persons to exhibit the barbiturate effects, some persons being profoundly unconscious while others receiving the same dosage would be only lightly so. This, of course, affected the amount of coramine necessary to counteract the barbiturate. These same observations hold true for the type of barbiturate used. Evidently, the ability of the coramine to counteract the effects produced by the barbiturates in man depend not only upon the chemical-physical antagonism existing between the two drugs, from a medical point of view, but also upon the ability of the coramine to combat the affinity of the individual's body for the barbiturate.

The unexpected reactions obtained during the use of the coramine such as hiccoughs, vomiting and flushed skin were not felt to be alarming and could not be construed as disadvantageous to the use of the drug.

It was rather surprising, too, that some of the expected reactions to coramine did not occur, i.e., increase in pulse rate and volume, and increase in blood pressure. All of the results obtained in this respect were considered to be within normal physiological limits.

The site wherein the annulment of the barbiturate action by the coramine occurs is not known, but the bulk of the evidence existing in literature would indicate it as the central nervous system, probably the medulla and diencephalon. The mechanism of this annulment is even more obscure than the site, the mechanisms which have been described being entirely too technical for the purpose of this paper.

But, whether the site is definitely located, or the mechanisms understood, the fact remains that coramine is an interesting drug, and possesses definite possibilities in the counteraction of the effects produced by the barbituric acid derivatives. These possibilities certainly warrant further investigation, for a rapidly act-

ing drug possessing a wide margin of safety and reasonably certain in its ability to counteract the effects of the barbituric acid derivatives is an absolute necessity in any community where barbiturates are used.

SUMMARY

1 A study of the effect of coramine on individuals under the influence of barbituric acid derivatives is presented

2 The physiological reactions of these individuals to coramine are described

3 It is concluded that for the purposes of the experimental procedure herein described, coramine proved to be an excellent drug to counteract the effects produced by the barbiturates

FREQUENCY OF ACTIVE TUBERCULOSIS IN A HOSPITAL FOR MENTAL DISEASES*

With Special Reference to Schizophrenia

BY DAVID ROTHSCCHILD, M.D.† AND MORRIS L. SHARP, M.D.†

IN modern psychiatric teaching there has been general acceptance of the view that psychic and somatic phenomena are closely interrelated aspects of the human organism. This conception lends new significance to studies of the incidence of different somatic diseases in patients suffering from mental disorders. Tuberculosis offers itself as a favorable object of such a study because of its wide distribution and the ample data available concerning its frequency in the general population.

It is commonly stated that tuberculous disease is much more prevalent in mental hospitals than in the country as a whole. Furthermore, there is a widespread belief that patients with schizophrenia are especially prone to develop active tuberculosis. If these observations are correct, the question at once arises whether the differences are merely incidental or whether they are part and parcel of some general disturbance which affects somatic as well as psychic

aspects of activity. The latter standpoint has been advocated by Freeman¹ and by Whit². Freeman¹ believed that there was a constitutional predisposition to tuberculous disease in schizophrenic individuals. White² explained its frequent occurrence in dementia praecox on the basis of a correlation between psychologic and somatic reactions. He pointed out that the schizoid psychoses are noncompensatory or decompensating in type in the sense that the patient with dementia praecox on the whole shows little active tendency to get well or to develop a compensatory type of psychologic reaction. In other words, the patient succumbs to the stresses that bring about his psychosis and deteriorates. In harmony with this reaction at the psychologic level one finds at the somatic level a similar type of reaction to the tuberculous infection. Such persons not only are easily infected relatively speaking, but easily die of tuberculosis. Thus according to Whit², a person who presents the capacity for compensatory reactions will be found to present this capacity not only in his somatic reactions but

*From the Foxborough State Hospital.
Read at a meeting of the Massachusetts Psychiatric Society December 13 1935.
†Rothschild, David—See for Physician and Director of Nurses in Foxborough State Hospital. See Dr. Morris L. Sharp—Junior Assistant Physician, Foxborough State Hospital. For record and address of authors see This Week Issue, page 916.

also in his psychologic reactions. To some European authors^{3, 4} the association of tuberculosis and schizophrenia has been striking enough to suggest that certain types of dementia praecox may be caused by the toxic effect of tuberculous infection on the central nervous system. On the other hand, Bogen, Tietz and Grace⁵ have recently denied that the incidence of clinical tuberculosis was appreciably affected by the type of psychosis.

It is evident even from this brief discussion that there is no general agreement concerning the significance of the observations dealing with tuberculosis and its frequency of occurrence in mental disorders. We therefore thought it worth while to reexamine the whole subject in the light of our own observations at a hospital for mental diseases.

RESULTS

A survey was made of the deaths from tuberculosis occurring in the Foxborough State Hospital from 1920 to 1934 inclusive. Owing to the small number of cases in many of the psychoses dealt with, separate figures were determined only in schizophrenia, which formed the largest group. The data are presented in table 1. A total of 1016 deaths from all causes occurred during this period. Tuberculosis accounted for 102 of the fatal cases, or 10 per cent of the total. This included 60 male and 42 female

patients. All but 6 members of the group were diagnosed as cases of active pulmonary tuberculosis. Two patients presented tuberculosis of the kidneys and 4 acute miliary tuberculosis.

The average death rate from tuberculosis during the whole period under review was 65 per thousand patients. The average rate was 9.93 per thousand for the years 1920 to 1924, 6.53 per thousand for the years 1925 to 1929 and 4.79 per thousand for the years 1930 to 1934 inclusive.

Sixty-five patients who showed active infection, or 63.7 per cent of the whole tuberculous group, were diagnosed as cases of schizophrenia. The average duration of the somatic disease was approximately six months in both the schizophrenic and the nonschizophrenic cases. The average length of time spent in the hospital before symptoms of tuberculosis were detected was 4.8 years in the former group and 5.6 years in the latter. Clinical evidence of the disease was observed on admission in 22 of the patients, 8 of whom were suffering from dementia praecox.

Since the diagnosis was in many instances based solely on clinical observations, an attempt was made to verify the accuracy of the figures by comparing them with those obtained from the postmortem examinations made during the same period. Necropsies were performed in 373 cases, of which 45, or 12.1 per cent, showed ac-

tive tuberculosis. This figure is only slightly higher than that obtained for the whole group and in view of the smaller number of cases it is doubtful whether the difference is of any significance.

DISCUSSION

Our figures do not differ radically from those recorded in the recent literature and therefore probably provide a representative sample in spite of the small size of the group. Methe and Brink⁶ found that the percentage of deaths due to tuberculosis in Ontario hospitals ranged from 9.5 to 10.66 per cent in the years 1925 to 1932. During the same period our figures fluctuated between 4.71 and 10.93 per cent. Wechsler⁷ in Switzerland stated that 6.01 per cent of the deaths occurring in a mental hospital from 1921 to 1931 were caused by tuberculosis. According to Malzberg⁸ this disease was responsible for 9.5 per cent of the deaths taking place in New York State Hospitals. In

were respectively 9.93, 6.53 and 4.79 per thousand in the hospital group and 1.22, 0.996 and 0.749 per thousand in the adult population of Massachusetts.* Thus the death rate was 8.13 times greater among our mental patients than in the adult population of the state during the first five-year period, 6.56 times greater during the second period and 6.39 times greater during the final period. Higher figures were obtained by Malzberg⁸ and Freeman¹. Freeman¹ found that the mortality rate among mental patients was about ten times that of the population at large. Malzberg⁸ stated that the patient death rate from tuberculosis in New York State Hospitals during the years 1929 to 1931 inclusive was 8.28 per thousand, exceeding that of the general population in the ratio of 11.7 to 1. In spite of this difference the proportionate mortality from tuberculosis in our group was very similar to that reported by Malzberg⁸.

It is interesting to note that the patient mortality rate from all causes was also increased

Data supplied by L. Vernon S. Pope of the Division of Tuberculosis, Massachusetts Department of Public Health.

the years 1929 to 1931 inclusive. Data obtained by Warren and Canavan⁹ in 802 autopsies in Massachusetts State Hospitals for Mental Diseases showed that tuberculosis accounted for 11.7 per cent of the fatalities. Freeman¹ reported that a diagnosis of active tuberculosis was made in over 17 per cent of 5600 cases in which postmortem examinations were performed. His higher results may perhaps be accounted for by the larger proportion of colored patients in his group for he found that the tuberculosis mortality rate of the colored population was two to four times that of the white population.

The observations presented here confirm the generally accepted view that tuberculosis disease is commoner among patients in mental hospitals than in the outside population. Since the vast majority of our patients were twenty years of age or over comparisons have been made with adult groups. In table 2 the data are arranged for the three five-year periods included in the present study. The average mortality rates from tuberculosis for the years 1920 to 1924, 1925 to 1929 and 1930 to 1934 inclusive

being from 3.94 to 4.39 times higher than the general mortality rate of the adult population of the state* during the periods under consideration (table 2). Malzberg⁸ found that the death rate in mental hospitals was 7.4 times greater than that of the general population, but after making corrections for differences of age the ratio of the two rates was 4.7 to 1. Even with this general increase it can be seen from table 2 that the proportionate mortality from tuberculosis is consistently higher among our patients than in the adult population of the state.¹

The majority of the deaths from tuberculosis occurred in patients with schizophrenia. It has been frequently pointed out that tuberculosis occupies first place in the list of causes of death in cases of dementia praecox. One third of our patients with this psychosis who died during the period under review presented evidence of active tuberculosis. The corresponding figures

*The figures for the adult population, which included persons twenty years of age and over, were kindly supplied by Dr. L. Vernon S. Pope of the Division of Tuberculosis, Massachusetts Department of Public Health.

of Freeman¹, Malzberg⁸, Wechsler⁷ and Low¹¹ were 30.94 per cent, 28.4 per cent, 14.74 per cent and 50 per cent, respectively. In contrast to these high figures in dementia praecox, active tuberculosis was noted in only 4.5 per cent of the deaths occurring in all other types of psychosis.

At first sight these observations seem to suggest that the incidence of tuberculosis is much greater in the schizophrenic population than in patients with other psychoses. However, an analysis of our data does not wholly bear out such a conclusion. The schizophrenic group accounted for only 19 per cent of the total deaths though it constituted approximately half of the hospital population. According to Malzberg⁸, the death rate of patients with dementia praecox is less than half that of all patients with mental disease. This is largely due to the fact that many toxic and organic factors that are seldom encountered in schizophrenic psychoses are common in other types of mental disorder. When the higher general mortality in the latter psychoses is taken into consideration it becomes evident that tuberculosis is actually more frequent in them than the percentage of deaths attributed to the infection would indicate.

The data necessary for an exact comparison are not available, but an approximate idea of the relative frequency of active tuberculosis in the two contrasted groups may be obtained from the following considerations. The figures for the resident population show that 51.6 per cent of the patients in the Foxborough State Hospital¹² on September 30, 1933, were classified as cases of dementia praecox. If the hospital population remained stationary with tuberculosis equally distributed among all types of psychosis, about half of the deaths would fall within the schizophrenic group, as compared with a figure of 63.7 per cent actually obtained. Of course, the hospital population is constantly changing, but these changes tend to favor higher mortality rates from tuberculosis in dementia praecox. We refer to the well-known circumstance that patients with schizophrenia remain on an average for a considerably longer time in the hospital than most of the other patients, and thus the period during which tuberculous disease may develop is longer in such cases. That this time factor is of importance is suggested by the fact that the average period spent in hospital before symptoms of tuberculosis were detected was approximately five years, a period which is longer than the average duration of residence observed in many of the non-schizophrenic psychoses. Here we might add that the recent observations of Bogen, Tietz and Grace⁵ lend support to our standpoint, for they found that the incidence of clinical tuberculosis increased with the length of stay in the institution.

In view of the considerations discussed above it is our impression that there is no great difference between schizophrenia and the other types of psychosis with respect to the frequency of active tuberculosis in them. This conclusion is in accord with the observations of Malzberg⁸, who found that the standardized death rate from pulmonary tuberculosis among patients with dementia praecox exceeded that among all patients only in the ratio of 1.1 to 1. At the same time, it should be remembered that patients with psychoses other than schizophrenia are subject as a group to a very high mortality from all causes, so that tuberculosis is in reality not more frequent, relatively speaking, than other somatic diseases. In schizophrenia, however, tuberculosis is the leading cause of death, and in this sense we may speak of an increased susceptibility to tuberculosis in dementia praecox as compared with other psychotic conditions.

McGhie and Brink⁶ suggested that the increased frequency of tuberculosis in mental hospitals may be attributed to several factors such as the presence of undetected active cases in wards which are often overcrowded, a generally under par physical condition of many mental patients and the difficulty experienced with some patients in obtaining an adequate intake of food. Bogen, Tietz, and Grace⁵ believed that the infection developed not as a result of the mental disease, per se, or as its cause but from the conditions of confinement and exposure to infection resulting therefrom. These factors are undoubtedly of importance, but it is probable that they are more important in the nonschizophrenic group, in which numerous physical factors may impair the general health of the patients. In the schizophrenic group predisposing factors of this type are much less common. We must, therefore, look for other explanations of the increased susceptibility of schizophrenic patients to tuberculous disease. The view that dementia praecox is actually caused by the toxic effects of tuberculosis is open to many objections and has not been accepted by the great majority of workers owing to the lack of reliable evidence as to its validity.

The question now arises whether White's² theory of a correlation between psychologic and somatic reactions can account for the increased frequency of tuberculous infection in patients with dementia praecox. In this connection we would like to point out that there are great variations in the severity of the decompensating psychologic reaction observed in schizophrenic psychoses. An attempt was therefore made to determine whether there was any relation between the degree of psychologic decompensation and the occurrence of tuberculous disease. A scrutiny of the sixty-five cases of dementia praecox in which active tuberculosis was noted showed that hardly any of the patients had made even a moderately successful adjustment

to the comparatively simple environment of a state hospital. The great majority displayed profound deterioration with little ability to retain or develop any interest in the outside world. Most of them had been idle, inactive, and apathetic for years, in some cases periods of restlessness were observed from time to time. Only eleven members of the group had been engaged in any type of work during the years immediately preceding the onset of the tuberculous disease and even though the work was very simple in nature, it was usually performed irregularly and inefficiently. In contrast to this, a survey of the whole male schizophrenic population showed that slightly more than 50 per cent of the patients were regularly employed in useful occupations. We may therefore say that tuberculosis tends to occur in patients who show the least active tendency to get well mentally and who thus represent the most out-poken examples of a decompensating psychosis within the schizophrenic group.

These observations at first seem to confirm the view expressed by White.² On further consideration, however, they may be interpreted in other ways. One might argue that the patients who are unable to reach a level of mental activity approaching the normal show an increased tendency to develop tuberculosis merely because they are especially liable to present faulty and unhealthy habits and at the same time are closely confined for prolonged periods. Other authors refused to accept such a view but stress the importance of an underlying constitutional factor. Freeman¹ found that the mortality rate from tuberculosis in epileptics is only a fifth of the rate in schizoid individuals, in spite of the fact that the confirmed epileptic may resemble in many outward respects the patient with long-standing dementia praecox. One might also mention Luxenhurger's¹³ work which showed that tuberculous disease was commoner among siblings of schizophrenic patients than in the general population.

In our opinion these two interpretations are not mutually incompatible. It is probable that the increased susceptibility of schizophrenic patients to tuberculosis is due to a combination of the two factors, unhygienic modes of life with prolonged hospitalization on the one hand, and a lowered resistance which is correlated with decompensating mental reactions on the other.

Finally we would like to point out that, regardless of the factors involved, the mortality rate from tuberculosis in the hospital population has dropped from 9.93 per thousand in the years 1920 to 1924 to 4.79 per thousand in the years 1930 to 1934, a decrease of slightly more than 50 per cent. In the adult population of the state the rate has shown a drop of 39.7 per cent during the corresponding periods (table 2). An analysis of the data in table 1 indicates that

the decrease was more pronounced in the schizophrenic group than in the other psychoses, suggesting that the improvement in the former particularly cannot be entirely accounted for by improving conditions in the population at large. The decrease in the frequency of tuberculosis among our mental patients is probably to be attributed to the greater emphasis placed on outdoor activities, physical occupation, adequate housing, and early segregation of active cases in recent years. It is interesting to note that the first two measures really belong in the field of occupational therapy, which has proved to be of definite benefit from a mental angle in patients with schizophrenia. The mortality from tuberculosis remains high, but the fact that it has already diminished considerably suggests that more intensive efforts along the lines mentioned should lead to still further improvement in the future.

SUMMARY

A survey of the deaths from tuberculosis during the years 1920 to 1934 was made at a state hospital for mental diseases.

The average mortality rate from tuberculosis during the whole period was 6.5 per thousand. The average rates for the years 1920 to 1924, 1925 to 1929 and 1930 to 1934 inclusive were respectively 9.93, 6.53 and 4.79 per thousand. These figures were respectively 8.13, 6.56 and 6.39 times greater than the death rates from tuberculosis in the adult population of Massachusetts during the corresponding five-year periods.

Although 63.7 per cent of the deaths from tuberculosis occurred in patients with schizophrenia, an analysis of the data showed that the incidence of active infection in dementia praecox did not differ greatly from that in all other psychoses considered as a group. In the latter, tuberculosis is not more frequent, relatively speaking, than other somatic disease. In contrast to this, tuberculosis is the leading cause of death in cases of dementia praecox, accounting for one third of the fatalities in that group, and in this sense one may speak of an increased susceptibility to tuberculous disease in patients with schizophrenia. This increased susceptibility is probably based on unhealthy habits, prolonged hospitalization and a lowered resistance which is correlated with decompensating types of mental reaction.

CONGENITAL DEFECT OF THE PECTORAL MUSCLES

BY RUFUS R. LITTLE, M.D.*

A REVIEW of the literature on congenital defects of the pectoral muscles immediately impresses the reader by the apparent rarity of this condition. As observed by Bennett¹ the American literature contains very few reports of congenital defects of pectoral muscles by far the greater number of cases coming from foreign sources. In fact, only seventeen cases were found to be recorded in the literature of the United States during the past fifteen years. As the deformity caused by absence of the pectoral muscles is apparent even on casual physical examination, it is to be wondered that more cases have not been recorded, especially if one accepts the estimate of Bing (quoted by Christopher²) that congenital absence of the pectoralis major and pectoralis minor muscles together comprised 28 per cent of the total of cases of congenital absence of muscles in a series collected by him. Probably this figure is somewhat high, as pointed out by Jones³. After an extensive search of the literature, Moilev in 1923 found that about 220 cases of congenital defects of the pectoral muscles had been recorded up to that time. There have been comparatively few additions to that number. In reporting eight cases, Moilev⁴ states that five of these were seen in five months, and suggests that the condition is more common than is believed.

Several varieties of defects have been noted. It is agreed by observers that the most common abnormality found is absence of the pars sternocostalis of the pectoralis major together with absence of the pectoralis minor. One case of complete absence of the right pectoralis major muscle is recorded by Severn⁵, it being proved at autopsy that the right pectoralis minor and both left pectoral muscles were present and well developed. There appears to be no predominance of the occurrence of pectoral defects on the right or on the left side. Only one case has been reported where the condition was bilateral³. Obviously, clinical detection of absence of the pectoralis minor alone is impossible, and as no such case had been recorded from the dissecting room, Christopher² concluded that "absence of the pectoralis minor

unaccompanied by defects of the pectoralis major probably does not occur." However, Williams⁶ later reported the case of a man who was operated on for carcinoma of the breast, and at operation the pectoralis minor muscle could not be found even by the most careful dissection, the pectoralis major being normal. This is admittedly a rare finding.

Various theories have been advanced concerning the etiology of pectoral defects. The condition is definitely congenital, yet heredity is not of great influence. One instance is cited of the condition being found in three members of one family³—father and two sons, and in other cases some congenital defect has accompanied the abnormality of the pectoral muscles, yet no conclusions can be drawn from these isolated occurrences. In one instance the condition was attributed to congenital syphilis⁶. However, this case lacked confirmation even by serological tests, and little support can be given to this explanation of the defect. It has been suggested that the condition may result from pressure of the forearm or knee of the fetus in utero, causing atrophy of developing muscle plates¹, or possibly theories relating to phylogenetic retrogression may be applied to congenital absence of these muscles. Probably the most acceptable view in regard to the origin of the condition is that of Lewis⁷, who attributes it to an embryological defect. He has shown that the anlage of the pectoral muscles is situated in the lower cervical region in the early embryo. As the embryo develops, the pre-muscle mass enlarges and moves downward, becoming attached first to the clavicle, then to ribs, sternum, and abdominal fascia, at the same time becoming differentiated into major and minor muscles. Lewis believes that the defect results from failure of attachment and subsequent atrophy of the pars sternocostalis of the pectoralis major and of the pectoralis minor, or to lack of complete differentiation between the two muscles. To lend weight to these theories is the fact that in practically all reported cases of congenital defects of the pectoral muscles the presence of the clavicular portion of the pectoralis major is acknowledged, with absence of the pars sternocostalis and of the pectoralis minor.

*Little Rufus R.—Assistant Physician, North Reading State Sanatorium. For record and address of author see This Week's Issue, page 946.

All observers are in agreement concerning the extremely slight disability resulting from absence of the pectoral muscles. Repeatedly cited is the case of Burke* of a good left handed baseball pitcher with this abnormality on the left side. Other reports all confirm this observation the patients themselves usually being unaware of the condition. As the action of the pectoral muscles is closely associated with that of the deltoid, subclavius, and other muscles of the shoulder girdle, compensatory action of these muscles inhibits any disability that might result from defects in the former. The pectoralis major "if acting alone adducts and draws forward the arm bringing it across the front of the chest, and at the same time rotates it inward."¹⁰ This action appeared to be entirely unimpaired in the case to be described herein. The pectoralis major, the pectoralis minor, and the subclavius muscles belong to the group of auxiliary muscles of respiration and are very important agents in forced inspiration. That defects of the pectoral muscles limit forced inspiration is indicated by the findings in the case being reported in this paper, expansion of the affected side being less than that on the normal side.

The deformity caused by pectoral defects as previously stated is quite apparent. The affected side of the thorax is flattened and the ribs are plainly visible and palpable beneath the skin and subcutaneous tissue. It is said that deformities in the nipple and breast are often present, and complete absence of the breast and nipple has been reported.¹¹ There may be defects in the underlying ribs, the cartilaginous portions often being distorted or absent.

Following is the report of a case which illustrates many of the commonly recognized findings in congenital defects of pectoral muscles and in addition presents a factor that may be of some clinical significance as the patient grows older.

This case is reported from a sanatorium for tuberculosis of children, the age limits for admission being one month and seventeen years. During the nine years in which this sanatorium has been reserved exclusively for children and with over 2000 admissions during this time this is the only case of congenital absence of the pectoral muscles that has been recorded thus giving a very rough estimate of the relative frequency of this condition assuming that repeated physical examinations of the chest would have detected such an abnormality.

Case report G. P., male white aged six years. The history as obtained from the mother of this patient records a normal noninstrumental birth. The mother states that deformity of the right chest has been noticed since the birth of the patient. The child has always been active and apparently in

good health although somewhat thin. In August 1934 one eye became inflamed and the patient was taken to a hospital for treatment. There diagnoses of phlyctenular conjunctivitis and childhood type

FIG 1 Illustrates the absence of the pectoral fold

FIG 2 Illustrate herniation of the lung upon increased intra thoracic pressure

tuberculosis were made and admission to a sanatorium was recommended. Upon admission the above diagnoses were confirmed. Roentgenogram of the lungs indicated childhood type tuberculosis, the pathology being in the hilar regions with no

demonstrable parenchymal involvement Upon physical examination of the chest, deformity of the right side was immediately apparent The right pectoral fold was absent, the underlying ribs being visible and palpable directly beneath the skin. The right side of the thorax was flat and poorly developed in contrast to the left side, which was of normal appearance Measuring from midlines anteriorly and posteriorly, the circumference of the hemisphere formed by the right thorax was 4 cm less than that of the left or normal side Expansion of the right side on forced inspiration was 1 cm, while that on the normal side was 2 cm, giving a crude idea of the impairment of the action of these auxiliary muscles of respiration On palpation, deformity of the third, fourth, and fifth ribs was detected, and confirmed by roentgenograms, their sternal ends being distorted and without cartilaginous attachment to the sternum, leaving between the ends of these ribs and the sternum, a comparatively large break in the continuity of the thoracic cage Through this opening, herniation of the lung was visible upon cough or any effort that tended to increase the intrathoracic pressure The presence of the clavicular portion of the pectoralis major was demonstrated by abducting and elevating the right arm, bringing this portion into relief Absence of the pectoralis minor was demonstrated by resisted effort on the part of the patient to draw the arm and shoulder forward, downward, and inward, the skin becoming lax and a hollow forming where the pectoralis minor would be if present

As in all previously reported cases of congenital absence of pectoral muscles, the function of the arm on the affected side was unimpaired, the patient being able to use this arm in any position fully as efficiently as the opposite arm But as previously pointed out, some impairment in the function of these muscles as auxiliary muscles of respiration may be detected, although this is probably of little clinical significance

The herniation described above, approximately the size of a lemon in this six year old boy, may eventually offer a surgical problem as he grows older and engages in strenuous physical activities, or in the event of the development of adult pulmonary tuberculosis with collapse therapy indicated

Severn⁵ observed that the absence of all effects resulting from defects of the pectoral muscles tends to show that a good functional result may be expected in patients whose pectoral muscles have been removed for malignancy This observation likewise applies to diversion of the pectoral muscles in certain forms of surgical treatment of pulmonary tuberculosis

Summary A brief review of the American literature on congenital defects of the pectoral muscles is presented Added to the list of previously reported cases is the report of a case with clinical manifestations that may be of potential significance

ACUTE, ULCERATIVE, TERMINAL ILEITIS AND COLITIS

A Case Report

BY THOMAS F CORRIDEN, M D *

THIS patient was admitted to the hospital on August 22, 1935 and remained there from that day until September 12 During that time she ran a temperature varying from 102° to 103° every evening

On admission she gave the following history For the past month she has had pain across the lower abdomen soon after eating Sometimes she has had to sit down and hold her hands to the abdomen because the pain was so severe It usually passed away in a short time Lately the pain has occurred more frequently and lasted longer, not altogether associated with eating For the past few days she has been nauseated, and vomited bitter-tasting yellow fluid Occasionally she has had headache There has been no diarrhea The bowels have been very constipated and the stools scanty, light yellow in color She has taken no cathartics There has been some epigastric pain at times The evening of entrance she was so nauseated and had so much pain that a doctor was finally called He referred the patient to the hospital

She has had the usual childhood diseases such as measles, mumps, whooping cough and sore throats,

but has not yet begun to menstruate Until now, she had had no abdominal pain or digestive trouble

Physical examination on admission A well-developed, rather emaciated white female aged 14 years, complaining of abdominal pain Head Eyes are equal and regular, reacting to light and accommodation There is no nystagmus, external ocular movements are negative External examination of the nose and ears negative Mouth Teeth in fair condition The tongue is moist and moderately coated, protruding in the midline without tremor The tonsils are moderately enlarged but not markedly reddened Neck There is no cervical adenopathy, no stiffness Chest Lungs, expansion is symmetrical and there are no areas of abnormal dullness and no adventitious sounds Breasts negative The heart is not enlarged, rhythm regular, rate 90 B P 98 systolic, 58 diastolic. There are no thrills, rubs, or murmurs The point of maximum impulse is in the 5th interspace within the midclavicular line The abdomen is tender and rather doughy in consistency throughout, but more marked in both lower quadrants No evidence of fluid The extremities are negative except for rather marked hypertrichosis Knee jerks, biceps, triceps, and reflexes are moderately hyperactive No pathological reflexes and no sustained clonus Rectal and pelvic examination not done

*Corriden Thomas F—Surgeon Cooley Dickinson Hospital Northampton Mass. For record and address of author see This Week's Issue page 946

On August 24 there was more marked epasm and tenderness in the right lower quadrant than elsewhere in the abdomen.

The following were the laboratory findings:
Wassermann negative.
Widal negative.

Stool: No parasites seen (Amoeba or Tapeworm).
Agglutination test for undulant fever was negative.
Blood culture—no growth in forty-eight hours. No growth in eight days.

Stool: Gualao test shows a very faint trace of blood.
Occasional pus cell seen in wet sediment. Culture: B. Coll.

On September 13 under gas oxygen and ether a midline incision extending from the umbilicus to the symphysis was made. On opening the peritoneum approximately 100 to 150 cubic centimeters of

made a very satisfactory convalescence. She was discharged from the hospital approximately fourteen days after the operation. During the course of time there was a marked improvement in the constipation of which she had complained. Beginning about four days following the operation, she began to have rather normal bowel movements and at the time she was ready to leave the hospital she had begun to put on weight and have normal bowel movements with no cathartics. The last report I had was that she had gained twenty pounds and had gone back to school.

Pathological report by Dr. Frederick Jones: The tissue received for examination consists of terminal ileum, cecum and appendix. The tissue as a whole feels edematous and doughy. The serosa is pale grayish red glistening and smooth. The opening of the ileocecal valve is considerably smaller than normal.

				Specific Gravity	Albumin and Sugar	Microscopic
On admission	light amber color	slightly cloudy	and	1.011	negative	{rare pus amorphous urates round and squamous bacteria
September 3 1936	cloudy amber color		acid	1.011	negative	
						{rare pus, round and squamous

free, straw-colored fluid was found in the abdominal cavity. Beginning about 18 centimeters from the ileocecal valve, the small bowel was markedly distended with gas. The terminal portion of the ileum was thickened and had a doughy sensation on palpation. The mesentery was markedly edematous and scattered throughout were a great many glands varying in size. Exploration of the appendix disclosed it to be normal in all respects. The proximal portion of the cecum for a distance of about 16 centimeters gave the same doughy sensation with edema and glands in the mesentery. Considering the course this patient had run it was decided to resect the area involved. The terminal 18 centimeters of the ileum and the 16 centimeters of the proximal part of the cecum were then clamped off and the ileum and cecum together with the appendix were resected. The cut ends were inverted, and a lateral anastomosis was done. The mesentery was sutured. A Penrose drain was inserted near the suture line. The abdomen was closed and sutured and the patient was sent back to bed.

Microscopic examination: The examination showed practically the same condition as has been described upon opening the abdomen except for the fact that the lumen of the ileum had narrowed to such an extent that only a lead pencil would pass through it.

Following the operation, the patient ran a rather stormy course for the first two days but gradually quieted down. There was at no time any fecal discharge from the drainage area. At the end of four days the Penrose drain was removed and the patient

On opening the intestine the mucosa is red to grayish red in color except for small areas of deeper red which surround numerous denuded small patches of mucous membranes. These small ulcers have a dark gray center surrounded by an area of hyperemia. These necrotic areas are found in the ileum and cecum extending for a distance of 17 centimeters into the ileum and approximately 15 centimeters into the cecum.

Microscopic examination of sections from the ulcerated areas present the following picture: The mucosa shows complete necrosis and destruction. This process of necrosis extends through the muscularis mucosa and into the submucosa, but does not involve the circular or longitudinal muscle fibers.

These ulcerated areas are covered with an exudate consisting of necrotic epithelial tissue in which are found numerous polymorphonuclear cells, plasma cells and a few lymphocytes. Toward the base of the ulcers are many newly formed capillaries and young fibroplastic tissue containing numerous plasma cells, lymphocytes and an occasional eosinophil.

There is some edema in the submucosa and the solitary lymph follicles are hyperplastic. Perivascular lymphocytic infiltration is found throughout the submucosa and a few endothelial leucocytes and eosinophils are also noted. Beyond the edges of the ulcers the vessels of the mucosa are dilated and filled with erythrocytes for some distance beyond the ulcer margin.

Diagnosis: Multiple ulcers of terminal ileum and cecum of unknown etiology.

CASE 22191

PRESENTATION OF CASE

A forty-four year old American watchmaker was admitted complaining of dyspnea and a "choked-up" feeling

Ten days before entry the patient developed malaise, weakness, and chilly sensations. He went to work on the following day but suffered from a sensation of fullness in the mid-chest associated with a desire to cough but an inability to do so. He continued to work for two days thereafter although his weakness was progressive and the peculiar sensation in his chest became worse. There was no associated pain but he rapidly became short of breath. A week before admission his chest felt filled up, he became nauseated and vomited a small amount of material which was neither blood stained nor coffee colored. At this time he fainted and remained unconscious for about five minutes. A physician saw him shortly afterward and found that he had a temperature of 103°. There were no chills or additional symptoms. The fever apparently subsided but he remained in bed up to his entrance into the hospital. During this time his dyspnea became much worse as did the "choked up" sensation in his chest. He was able to lie flat in bed but occasionally was compelled to get out of bed and sit up in a chair. Two days before entry he noticed slight involuntary movements of his right hand which lasted for a few moments and then disappeared completely. The patient stated that he had no cough although his wife said that he had had a "bad cough" and mild night sweats for about two months. The cough was nonproductive. There was a loss of about ten pounds during the three or four months preceding admission.

For two years he had suffered frequent frontal headaches and had been taking a proprietary drug two or three times daily as a precautionary measure.

Physical examination showed a well-developed and nourished man who appeared to be acutely ill. The skin was cold, moist and exhibited a pale ashen appearance with cyanosis of the fingers and lips. The pupils were constricted and reacted sluggishly to light and distance. He

had been given an opiate prior to his admission. The retinal arterioles were rather tortuous. Oral hygiene was poor and the tongue was dry and coated. The left border of cardiac dullness was 12 centimeters from the midsternal line and the right border 6 centimeters. The apex impulse was palpated about 9 centimeters to the left of the midsternal line. The heart sounds were distant and of poor quality. The rhythm became totally irregular for several minutes at a time during the period of examination. In the intervals the rhythm was perfectly regular. The neck veins were distended with the patient in the sitting position. The blood pressure was 110/80 and during inspiration no sounds were heard over the brachial artery. There were numerous moist rales and wheezing respirations audible in the lower portion of both chests posteriorly and in both axillae. The liver dullness was percussed to a point three fingerbreadths beneath the costal margin although the edge was not felt.

The temperature was 98.6°, the pulse 82. The respirations were 25.

Examination of the urine was negative. The blood showed a red cell count of 4,720,000, with a hemoglobin of 70 per cent. The white cell count was 25,200, 90 per cent polymorphonuclears. A stool specimen showed a faintly positive reaction to the guaiac test. Several sputa examinations were negative for blood and tubercle bacilli. A sedimentation rate was 69 millimeters per minute. A Hinton test was negative. Several blood cultures were negative. A tuberculin test was negative.

X-ray examination showed a large heart shadow. There was an area of consolidation at the base of the right upper lobe and another area of consolidation with hazy margins at the right apex. On the left side there was homogeneous dullness in the lower portion of the lung field. The appearance of the left main bronchus was suggestive of an enlarged left auricle.

The patient's temperature exhibited daily fluctuations between 98° and 103° and the pulse varied between 80 and 120. Shortly after his admission a pericardial tap was done and 305 cubic centimeters of bloody fluid was removed and the patient's condition was considerably improved. The fluid contained 440,000 red blood cells and 7,000 white blood cells, most of which were polymorphonuclears. Cultures of the fluid gave no growth and examination for tumor cells and tubercle bacilli were negative. The paradoxical pulse and venous engorgement previously noted promptly subsided. Several pericardial taps were done thereafter for relief of dyspnea. Between taps the patient had rather constant asthmatic breathing which was relieved along with other symptoms by paracentesis. Five days after entry he complained of pain in the left lower leg. There was tenderness of the calf

muscles on this side and pitting edema at the ankle and foot. This subsided in about one week. Six days later transient coarse friction rubs were audible over both sides of the chest and a leathery rub was heard over the apex of the heart. Shortly afterward he became anasthenic and on the twentieth hospital day weakness and edema of the right hand and arm were noted. This became moderately more pronounced. A lumbar puncture showed an initial pressure of 380 millimeters with the patient sitting upright. The spinal fluid sugar was 71 milligrams. Only one lymphocyte was found and examination for globulin were negative. The total protein was 17 milligrams. Another x ray showed little more fluid in the left chest. The heart size and shape were unchanged. The area of consolidation at the base of the right upper lobe had almost disappeared, but the one at the right apex was still present. On the twenty-fourth day the patient had severe pain in the right anterior and posterior chest aggravated by respiratory movements. For several days there had been a palpable and audible wheeze on this side. A thoracentesis was done at the left base and 1,200 cubic centimeters of bloody fluid was removed. This showed a specific gravity of 1.016 and contained 110,000 red blood cells and 1,600 white blood cells of which 56 per cent were lymphocytes. Smears for tubercle bacilli and other organisms were negative. The patient's discomfort continued and he had periods of dyspnea and marked dyspnea. One month after admission a firm nodule about the size of a hockey nut became palpable in the right supracardiac region. At the same time several firm pea-sized nodules were felt in the subcutaneous tissue just lateral to the left nipple at the site of the previous paracentesis. He gradually failed and died one month after admission.

DIFFERENTIAL DIAGNOSIS

DR. GERALD BLAKE Will you demonstrate the x rays, Dr. Hampton?

DR. AUBREY O. HAMPTON The record is inaccurate. It mentions signs of fluid in the first film, but there is no fluid at the base in this first note, whereas it is evident in the second film. There is a rounded area of dullness here in the apex. There is pathology in the whole upper lobe, it appears to me. This lobe is small as one can see by the closely placed lung markings here and there. The heart is very large. None of the usual angles indicating the junction of the various heart chambers are visible and it very well might be due to pericardial effusion but the enlargement of the heart to the right is not so much as we would expect if it were due to fluid. We would expect cardiac enlargement plus pericardial distention.

DR. BLAKE Is that consolidation at the apex?

DR. HAMPTON Yes and it fades at the base. Then he developed fluid at the left base in about twenty days. The heart does not change. This is the left main bronchus which is pushed upward. There is a definite widening of the carina and even though that is a portable film I think we are justified in assuming that the left auricle was dilated.

This is the last film and the area at the right base has almost disappeared but the density of the right apex remains. He has a new shadow here at the left midlung field and the fluid is increased in the left pleural cavity. The changes in the midportion of the lungs may have been infarcts, I do not know why this one in the apex should remain and grow larger if it is an infarct.

DR. BLAKE From this patient's history it appears that he had a nonproductive cough and night sweats for two months previous to entrance, and that he lost ten pounds in weight during the three or four months before coming to the hospital. We may assume, therefore, that his illness began at that time. The sensation of fullness in his chest with a desire to cough and inability to do so is satisfactorily explained by the physical examination showing pericardial effusion. The finding that the effusion was bloody in character at once brings us to a consideration of the conditions which may bring this about. And in addition to the three things looked for while the patient was in the hospital—namely tuberculosis, subacute bacterial endocarditis and carcinoma—we must also consider Hodgkin's disease as a possible cause of such findings before ruling any of these in or out. I would call attention to the suggestion of uremia in this patient, particularly at the end of his illness when he showed coarse friction rubs over both chests and heart apex, increased pressure in the spinal fluid, disorientation, and the presence of bloody fluid in his thorax as well as his early symptoms of headache, one attack of vomiting with unconsciousness, the very slight involuntary movement of the right hand and pericardial effusion. All these could very well be explained on the basis of uremia. In spite of the fact that his one urine test was reported normal and in the absence of blood chemistry reports, I am inclined to believe that his late symptoms are best explained on a uremic basis.

We cannot however interpret the x ray lung findings on this basis nor the skin manifestations he showed before death. Subacute bacterial endocarditis has to be considered particularly if we interpret the lung manifestations as evidence of infarcts. However, the lesion at the apex of the right lung is not at all characteristic of infarct and there is a striking absence of peripheral embolic manifestations as well as

repeatedly negative blood cultures. In addition to this the nodules in the skin cannot be explained by such a diagnosis. Again with regard to tuberculosis the lesions in the lung are not characteristic, and repeated examinations failed to reveal evidences of this condition from the smears or the fluid. Nor could the skin lesions be satisfactorily explained on this basis. Hodgkin's disease must be considered as it is one of the things that may give the type of bloody pericardial fluid which was shown in this case, and may give the skin nodules which were described. The lesion at the apex of the right lung could be satisfactorily explained on the basis of Hodgkin's disease as could the skin nodules. There is, however, an absence of other manifestations of glandular enlargement either in the mediastinum or elsewhere, and a daily rise of temperature over a long period of time is not characteristic of this disease. However, I do not feel that it can be completely ruled out since the manifestations of Hodgkin's disease may be strikingly limited.

The appearance of the lesion at the right apex is fairly characteristic for carcinoma and I believe we can best explain this case on the basis of a primary carcinoma either here or in the mediastinum invading the pericardium, perhaps by direct extension, and later the left pleura and skin by metastasis. In addition to this, there was congestive failure at the start of the illness based on the pericarditis, and possibly an arteriosclerotic or rheumatic heart. There was, I believe, a terminal uremia, and some infection probably in the lung to explain the phlebitis in the left leg. My second diagnosis would be Hodgkin's disease.

DR TRACY B MALLORY: Are there any other suggestions?

DR WYMAN RICHARDSON: Did you examine the brain in this case? I was wondering whether he might not have a metastatic tumor of the brain, probably bronchiogenic carcinoma.

DR MALLORY: Dr Bock, you saw this man. Will you tell us your opinion?

DR ARLIE V BOCK: As Dr Blake said, the man on admission was in shock, showed evidence of extreme cardiac tamponade and was greatly relieved by paracentesis. The removal of bloody fluid was not of much help, so far as the character of the fluid went, in making a diagnosis. The relative brevity of the history made one think of the possibility of rheumatic pericarditis and pancarditis. He was rather old, had no supporting history, and we ruled it out on that ground. We thought of the possibility of tuberculosis of the pericardium, tuberculous pericarditis, with fluid. Nothing else in the picture seemed to fit that diagnosis. Then the final conclusion was that, in view of the rapidity with which he went downhill, he prob-

ably had a malignant process in the background, presumably from a primary lung carcinoma, and that he did have very likely, in view of the earlier symptoms, a left cerebral metastasis.

DR JOHN H TALBOTT: There are two items not mentioned which are worth noting in regard to this patient. The onset of symptoms was sudden and the duration of symptoms was short. Presumably he was well until only a few days before he came to the hospital. Secondly, the amount of fluid removed from his pericardial sac was interesting. He was admitted about the same time as was a younger man suffering from rheumatic pericarditis with effusion. The physical signs showed about the same degree of effusion in both patients. Yet the amount of fluid removed from this patient was much less than from the boy with rheumatic pericarditis. The amount of fluid removed was progressively less with each tapping, and the physical signs remained unchanged. The signs of constricting pericarditis were very impressive.

DR BOCK: I think that is an important point in view of the findings. He did not consider himself incapacitated until a very few days before admission and then his presenting story was substernal discomfort and shortness of breath.

CLINICAL DIAGNOSES

Malignancy involving the pericardium and the lung
Bronchiogenic carcinoma?
Metastasis to the brain (left cerebrum)?
Tuberculosis?

DR GERALD BLAKE'S DIAGNOSIS

Carcinoma of the lung invading the pericardium

ANATOMIC DIAGNOSES

Carcinoma of the lung with extension to the pericardium, metastases to the brain and left adrenal, and implantation on the thoracic wall
Pleuritis, acute and chronic
Pericarditis, acute and chronic
Pulmonary edema
Pulmonary atelectasis, left lower
Edema of the lower extremities

PATHOLOGIC DISCUSSION

DR MALLORY: The dramatic thing at the autopsy was the appearance of the pericardium. As soon as the sternum was removed we found this enormous, firm pericardial sac. It varied from a centimeter to over 2 centimeters in thickness and I think that perhaps accounts for the peculiarity of the x-ray shadow which Dr Hampton pointed out. A pericardial effusion, as he pointed out, usually produces more of a

shadow on the right but this man's pericardium was so thick it could not be distended by the fluid. Most of what was seen at x ray examination was actual cancerous thickening of the pericardial wall rather than effusion. The latter was at no time very great and by the time of autopsy had almost disappeared entirely and the inner and outer layers of the pericardium were almost completely fused. The question then, of course, came up as to where this tumor was primary. We found a good sized tumor nodule at the apex of the right lung. We dissected down all the major bronchi very carefully and could not find any sign of involvement. We know of course that the vast majority of tumors of the lung take origin in a bronchus and usually in a bronchus of significant size. There is no theoretical reason however, why it may not arise in one of the small bronchi close to the periphery of the lung and in that case it would be impossible to prove it in gross. That is what we believe was the case here. In a very careful search of the rest of the body we were able to find tumor in only two other places. There was a metastatic lesion in the brain, as was predicted, and there was also a small metastasis in the adrenal. The cancer could not have been primary in the brain and it is very improbable, it seems to me that it was primary in the adrenal. That has all the characteristics of metastasis. Our experience here is that adrenal metastases are practically the commonest secondary deposits from primary cancers of the lung.

Dr. J. H. MEANS. Dr. Mallory, there was a lesion in the x ray that looked exactly like a small infarct and apparently disappeared. Was there any explanation for that?

Dr. MALLORY. We found one cluster of smaller nodules of tumor in that right lung which we believe were extensions from the primary one, and there was on the edge of the tumor mass an area of infarction in the lung. I also found on microscopic section an organized thrombus, so he may have had an infarct that was healed.

CASE 22192

PRESENTATION OF CASE

A sixty six year old native male was admitted complaining of inability to pass urine.

Except for occasional nocturia the patient had been well until one year before entry. At that time he began to pass blood with his urine. Occasionally he voided some clots which caused him considerable pain. During this period he noted that he was unable to void while lying on his back but only when on his hands and knees. After two weeks he passed a stone which measured about a quarter of an inch in diameter.

Thereafter the hematuria ceased but the patient developed nocturia of five or six times. There was no increase of diurnal urinary frequency or associated dysuria until ten days before admission.

At this time he noted considerable difficulty in initiating micturition and three days later was unable to void at all. He was attended by a local physician who inserted a catheter three times daily for the succeeding week. The patient passed considerable blood and some clots through the catheter. On the night before entry spontaneous urination became possible but the hematuria continued. For the week preceding his entry the patient had nonradiating pain in his right upper quadrant. The character of this pain was not noted.

His past history was negative except for attacks of indigestion for the past forty years.

Physical examination showed a thin, dehydrated old man who appeared to have lost considerable weight recently. The skin was oily and inelastic. Oral hygiene was very poor. Small firm bilateral axillary nodes were palpated. The chest was barrel shaped but the lungs appeared to be clear. The heart was normal. There was considerable tenderness in the right upper quadrant and right costovertebral angle. The prostate was moderately enlarged, particularly the left lobe. It was firm in consistency and smooth.

The temperature was 101.5°, the pulse 90. Respirations were 20.

Examination of the urine showed a specific gravity of 1.010. There was a trace of albumin and the sediment was loaded with red blood cells. The blood showed a red cell count of 3,890,000, with a hemoglobin of 65 per cent. The white cell count was 10,900. The nonprotein nitrogen of the blood was 42 milligrams per cent. The serum protein was 5 grams. A serum calcium was 11.01 milligrams and the phosphorus was 2.92 milligrams.

X ray examination showed a dense area of calcification, measuring 1 by 0.5 centimeters, in the lower pole of the left kidney. There was mottled increased density in the right side of the true pelvis. Marked arteriosclerosis was evident. The heart was not remarkable but the aorta was tortuous. There was an old tuberculous fibrous process in the right apex. A cystogram showed an irregular filling defect involving the left posterior half of the bladder. The catheter curved about this area. There was a round area of bony condensation in the left wing of the ilium.

On the second hospital day a bilateral vasectomy was done. The patient's temperature subsided to normal but he complained of constipation and gas pains. An indwelling catheter drained well but large pieces of questionable tumor tissue passed through it. On the third

postoperative day the patient vomited 20 ounces of pale, bile free, odorless fluid. Gastric lavage drained 22 ounces of residual content with a similar appearance. An electrocardiogram showed a single auricular premature beat. QRS_1 exhibited a low amplitude, S_2 and S_3 were prominent, and T_1 was flat. Q_4 was absent and T_4 was upright with a concave S-T₄. Two days later at 2:30 a.m. the patient complained of severe epigastric pain and developed repeated vomiting and board-like rigidity of the abdomen. Peristalsis was present but there was marked tenderness in the epigastrium and pelvic peritoneal floor. The white cell count was 23,000 and a plain film of the abdomen showed free gas in the abdomen beneath both leaves of the diaphragm. The patient's temperature rose to 100° but his pulse and respirations remained at 80 and 20 respectively. A laparotomy was performed three and a half hours after the onset of the acute pain.

DIFFERENTIAL DIAGNOSIS

DR. GEORGE G. SMITH: This is a complicated case because apparently there are two entirely separate factors involving different symptoms. This is the case of a man who entered because he could not pass water. The presenting symptom was hematuria. Two weeks ago he passed a stone after which the hematuria ceased but the patient had difficulty in voiding. He had to be catheterized, this started up a good deal of bleeding. Another complaint was that of non-radiating pain in the right upper quadrant. The only other possibly important factor in the history was that he had had attacks of indigestion for forty years. He was a dehydrated old man. Examination apparently showed not much that gave us any clue. The prostate was moderately enlarged particularly the left lobe. It was firm in consistency and smooth. He had some fever and there was blood in the urine. He had some anemia. There was no great increase in the non-protein nitrogen, which was 42 milligrams. The serum protein was somewhat low. The serum calcium was 11 milligrams, phosphorus 2.92 not particularly remarkable.

X-ray examination showed a dense area of calcification in the lower pole of the left kidney, and mottled increased density in the right side of the true pelvis. There was marked arteriosclerosis. A cystogram showed an irregular filling defect involving the left posterior half of the bladder. The catheter curved around this area. There was a round area of bony condensation in the left wing of the ilium. Of course we must look at this patient with the eyes and ears of the people who examined him. They did not state that the prostate was stony hard, which would have been suggestive of carcinoma, they saw merely it was firm in consist-

ency, and smooth. I should interpret that finding as meaning a hypertrophied prostate and not a malignant one. The cystogram shows a definite irregular filling defect involving the left posterior half of the bladder around which the catheter curved. It seems to me that if we take that at its face value we have to believe that there was a tumor of the bladder on the left side. The mottling and density in the right side of the true pelvis would be much easier to explain if they were on the same side as the filling defect in the bladder. In that case you would say that he had tumor of the bladder with calcium deposit in it. But seeing it on the other side makes one feel it has nothing to do with that condition in the bladder. As far as the examination goes, our diagnosis must be entirely guesswork. Urologists are perhaps fortunate in that they can get a much clearer picture of a case from the use of intravenous pyelograms and cystoscopy, than one can get in certain other branches of medicine, but here we are deprived of these aids to diagnosis. We do not know what an intravenous pyelogram would show. We do not know what the cystoscope would show. If we had this patient we would not be rash enough to make a definite diagnosis without knowing the result of these examinations. So we are forced to guess on the evidence we have here. That evidence would seem to show that the patient had a stone in the lower pole of the left kidney and apparently a tumor of the bladder near its base and on the left side. Why he has pain in the right costovertebral angle is difficult to explain. If the pain were on the same side that the tumor of the bladder was, one would explain it on the basis of obstruction of the lower ureter, but it is on the opposite side. If he has a tumor of the left base of the bladder, and has serious difficulty with his right kidney, one would not expect his nonprotein nitrogen to be so nearly normal as it is.

They did a bilateral vasectomy on him which is now preliminary to practically all prostatic and bladder operations.

He had an electrocardiogram but I do not know what it means. I do not believe it is important on the basis of this history.

"Two days later he had sudden severe epigastric pain and developed repeated vomiting and board-like rigidity of the abdomen." The only explanation that I can give, and it seems to me a perfectly obvious explanation of the abdominal condition, is perforation of a hollow viscus. With free gas in the abdominal cavity, sudden severe epigastric pain and board-like rigidity, I should think of a perforated gastric ulcer, possibly a duodenal ulcer, which might hook up with a history of attacks of indigestion for the past forty years. I can see no reason to think that this gastric condition or perfora-

tion is connected with his urinary condition. I remember one patient—I do not know whether this is the one—who developed an ulcer in his cecum a perforating ulcer and there was no cause found for it. The history sounds a little like this but I do not remember what the other factors were, except that I think he did have a tumor of the bladder.

On the evidence that we have, I should say we may diagnose a left renal calculus, a tumor of the bladder, and a rupture of a hollow viscus which, from the location of pain, I should think was probably in the stomach or duodenum. The condition of the right kidney, the cause of pain in the right kidney, I am unable to determine on the basis of the facts which we have at hand.

X RAY INTERPRETATION

DR. GEORGE W. HOLMES. There are several films missing in this case. Examination of the chest shows large bright lung fields suggesting a moderate amount of emphysema. The heart is not noticeably enlarged and the aorta is not unusually tortuous for a man of his age. We have not got the film of the upper part of the urinary tract to show the shadow described there. The shadow seen in the other films does not look like stone, but more like an undissolved pill in the gastrointestinal tract. The interesting thing in the x ray examination is this ragged filling defect in the bladder shadow with the catheter curved around it as described. That certainly looks like a tumor of the bladder possibly tumor outside the bladder pressing into it could produce a similar picture, but I think that is unlikely. I doubt if the changes described over the sacroiliac joint and in the sacrum are really important. So far as the x ray examination goes on the material we have here one would suspect a tumor of the bladder, probably malignant and no more.

DR. TRACY B. MALLORY. Dr. Breed would you care to comment on the electrocardiogram?

DR. WILLIAM B. BREED. The flat T_1 and the upright T_4 would certainly indicate the possibility of a coronary occlusion some time in the past.

DR. MALLORY. Dr. Colby have you any comment?

DR. FLETCHER H. COLBY. The only comment I have to make is that I am glad to see a genito-urinary surgeon make a diagnosis without cystoscopy. This man was in very poor condition when he came in on the ward and that is why he was not cystoscoped.

CLINICAL DIAGNOSES

Peptic ulcer with perforation
Peritonitis
Neoplasm of the bladder
Renal calculus (left)

Chronic myocarditis
Bronchopneumonia?

DR. GEORGE G. SMITH'S DIAGNOSES

Peptic ulcer with perforation
Tumor of the bladder
Renal calculus

ANATOMIC DIAGNOSES

Gastric ulcers, multiple
Operative wounds. Closure of a perforated gastric ulcer, bilateral vasectomy
Lobar pneumonia with multiple abscesses, bilateral
Carcinoma of the bladder with necrosis and extension to the left ureter
Renal calculus left
Pyelonephritis, left.
Pyonephrosis, left
Cardiac infarct, old healed.
Arteriosclerosis marked coronary with occlusion of left descending branch and marked aortic
Pericarditis, chronic fibrous.
Pulmonary emphysema, compensatory bilateral

PATHOLOGIC DISCUSSION

DR. MALLORY. This man was operated on and a perforated ulcer on the posterior aspect of the pyloric ring was found and sutured. He then developed signs of pneumonia and died in the course of a few days.

The autopsy showed, besides the sutured ulcer, two other ulcers on the anterior wall, all of them practically in the pyloric ring so that he had three gastric ulcers in all. The peritoneal cavity was almost perfectly clean. He had taken care of the infection there perfectly well. He did have extensive pneumonia with early abscess formation in the lungs, however. He had complete closure of the descending branch of the left coronary artery and an infarct of the heart, an old one. In the genito-urinary tract we found a stone in the left kidney with a completely atrophied kidney on that side and a dilated pelvis full of pus. The bladder itself showed a fairly extensive epidermoid carcinoma which had grown up the left ureter for a distance of about two centimeters.

A PHYSICIAN. Was there anything to explain the pain in the right kidney?

DR. MALLORY. Absolutely nothing.

A PHYSICIAN. Could compensatory hypertrophy of the kidney produce it?

DR. MALLORY. Sudden stretching of the kidney capsule will certainly produce pain but I would not suppose that compensatory hypertrophy would occur rapidly enough. If it did, contralateral pain should be the rule following surgical nephrectomies.

THE ENACTMENT OF HOUSE BILL 34*

THE passage of House 34, as amended in House 1720, represents the most important step in the progress of medical licensure in Massachusetts, since the establishment of the Board of Registration in Medicine in 1894.

The purpose of the Bill is to give increased protection to the health of the people of Massachusetts by raising the statutory requirements for qualification for the practice of medicine and this purpose would seem to have been clearly enough expressed in the original draft. The substantive objections, apart from the allegation that no legislation at all was necessary, were that insufficient protection by specific phrasing was provided for aggrieved applicants or aggrieved schools. The amendments have met these objections and a long step forward has been taken by Massachusetts.

So important is this legislation and so signal is the victory that there is glory enough for all who have participated in assisting the Bill on its difficult way. Where so many persons have

been interested in advancing the Bill, it may seem invidious to name any individuals, but it is not out of place to designate those acting in official capacity.

In the first place, chronologically speaking, the Board of Registration in Medicine deserves credit for persistently making the recommendation for change in the law in its annual report for a number of years, and for introducing a bill each year incorporating the recommendation, in spite of the discouraging outlook.

At the Hearing on the Bill, the Massachusetts Medical Society eloquently voiced its support through its President, Dr. Mongan, and the medical profession deserves great credit for its constant efforts, made not only through the officers of the Society, but through the individual members also, who by personal representations to members of the General Court accomplished so much in removing misunderstanding, overcoming prejudice and making clear the fundamental issue.

The Joint Legislative Committee on Education, under the Chairmanship of Senator Miles, the only physician in the Legislature, who has always vigorously supported the Bill, reported this Bill favorably, for the first time since the matter came up for legislative consideration. The House promptly approved the Bill, on second reading by a vote of two to one, and on third reading three to one. In the Senate the Bill was received unfavorably but on reconsideration gained strength as its true significance became better understood and on third reading the vote was two to one. The amendments in the House were accepted in the Senate where several more were added, the Bill gaining strength steadily as the discussion was prolonged, the House vote for enactment being four to one. Thus the supporters of the Bill in both House and Senate deserve great credit for their persistent efforts, for their willingness to accept strengthening amendments, and for their firmness in rejecting nullifying or invalidating proposals, which were made frequently by the opposition.

Then His Excellency, Governor Curley, deserves great credit for his insistence that the health of the people should be protected by the establishment of reasonably high minimum standards of medical education to be enforced by state control through a board of approval of medical schools, for his insistence that Massachusetts should take its proper place with the other states in exercising control over the medical education given to candidates who desire registration for practice, for his insistence that steps should be taken to make the Massachusetts license to practice medicine such that it will be accorded general recognition, for his insistence that medical schools chartered by the General Court shall become such that they

*The text of the bill appears on page 949 of this issue.

will be recognized by state boards of licensure throughout the United States finally for his insistence that all these ends shall be accomplished by a procedure which is just to the medical school, just to the applicant who seeks to practice medicine, and most important of all just to the patient whose confidence that the physician licensed by the state is really qualified and worthy of his trust, must not be betrayed.

In short the passage of this Bill reflects great credit on all who have supported it, and who have by their efforts placed Massachusetts where it belongs in the onward march toward better medical care for all the citizens of the Commonwealth.

THE HOUSSAY LECTURES

In 1911 the *Index Medicus* recorded the name of Bernardo A. Houssay as the author of an article entitled "Contribucion al estudio de la accion de los extractos hipofisarios en ensayo sobre la glándula cardio vascular del lobulo posterior." This appeared in a Mexican publication. As so often happens, this title of his first paper gave a definite indication of the direction which his interests would take. Since then the number of and wide range of learning demonstrated in his publications have been little less than phenomenal.

Professor Houssay has not only headed the department of physiology in the Faculty of Medical Science at Buenos Aires since 1919 and built up from very small beginnings a department which ranks with the best in the world but together with his associates and pupils has contributed much of the best and earliest work in many important fields of physiology.

Endocrinology in general, and especially that part of it concerning the pituitary, has been the focus of his greatest endeavor. This field is a particularly difficult one to study and one in which purely objective studies leading to definite, but conservative conclusions, are all too rare compared with the volumes of speculative, poorly controlled work that has appeared from certain sources. Professor Houssay's studies are never in the latter category and are all extremely valuable to the person who is working and studying any phase of medicine in which this gland is important.

The important relationship of the pituitary to the pancreas and to other glands has been the subject of some of his most valuable work. This type of study which goes to the roots of the physiology of such diseases as diabetes and hyperthyroidism is of fundamental importance to the practicing physician who sees such cases.

Unfortunately for many workers in the United

States practically all Professor Houssay's publications have been in Argentine, French, and Spanish Journals, many of which are not widely available in the United States even to those few students who can read Spanish. Last fall he made an extended tour in this country when he gave lectures under the Dunham Foundation at Harvard, the Lane Foundation at Leland Stanford, the Herter Foundation at Johns Hopkins, and the Eastman Foundation at Rochester. He also gave a Harvey lecture in New York and other lectures at the Universities of Chicago and of Pennsylvania, the Academies of Medicine at Los Angeles and San Diego, and before the American Association for the Advancement of Science. Next fall he is coming back to Boston as an honored invited guest to the Harvard Tercentenary and will take part in a symposium on "Various Aspects of Biology" at the Medical School on September 8.

The *Journal* has been fortunate in securing the lectures, delivered on his recent trip, for publication, and the first of the series appears in this issue. These articles will be the first, by Professor Houssay, to appear in the English language and will give a summary of his most important work. They also give most extensive references to his own and other original articles in this field taken from a wide survey of the world literature on the subjects. Reprints of the whole series, bound together, will be available for sale at a reasonable price soon after the whole series has been published. The exact price will depend on the probable demand. It is desirable that those who wish to apply for copies of these lectures do so promptly so that the demand can be gauged. Please apply to the *Journal*.

CUSHING'S "JOURNAL"

HARVEY CUSHING is the outstanding living American physician, both in surgery and in literature. Many years ago, he took a special field of surgery as his own. Building on the slender foundations of his predecessors—Horsley, MacEwen and Keen—he almost single handed, erected a substantial structure now copied all over the civilized world. Thus he rightfully takes his place as a world figure, honored wherever medicine progresses. In literature his "Life of Sir William Osler" has found a permanent place, one of the best of medical biographies. To those accomplishments he has now added another, perhaps, a hundred years from now to be considered his most enduring effort. "From a Surgeon's Journal" is his diary of his war time experience, written under the stress of conditions in the field. Ships at

sea, hospitals being formed in America and in action overseas, front-line dressing stations, the mud of Flanders, gassed and wounded troops, men with "chickens" on their shoulders and men without, bombing, illness and a host of friends and associates,—the pictures are deftly painted with the sure hand of a great surgeon and the clear eye of a penetrating, and yet sympathetic, mind. To those who shared, this fine book comes as an old friend, to sit by the fire-side with in a reminiscent mood, telling tales of bygone days. To the others, and particularly those boys too young to share, the diary presents a truthful picture of events which one hopes they will never see duplicated.

MILK COMPANY OFFICIALS INDICTED

It is now common knowledge, as well as a source of widespread amazement and concern, that the chief officials of the Whiting Milk Companies have been indicted by a Suffolk grand jury for distributing in large quantities, as fresh cow's milk, a grossly adulterated substance. During the milk shortage which accompanied the March floods, according to the contention of the Boston Health Department, the Whiting Milk Companies conspired to manufacture a product from an inferior grade of Dutch skimmed milk powder and rancid South American butter, over 100,000 quarts of this fluid were sold to chain stores in the poorer districts of Boston as *pure milk*, and indeed, so great was the supply of this spurious product that new markets were sought for its disposal!

We do not know how the criminal courts will decide this issue, nor should any case be judged until the evidence is submitted and the jury has rendered its verdict, but if this charge is substantiated, as gross a case of the sacrifice of public welfare to private greed will have come to light as has been heard of since pure food laws were first enacted. Unfortunately the record of this great concern, in which so many people have placed their confidence in the past, is not entirely clean, since in 1932 the Whiting Milk Companies were convicted of adding a foreign substance to milk and paid a substantial fine.

The public has a right to expect that the dispensers of food products should consider themselves as administering a public trust. Laws have been placed upon the statute books further to safeguard the public's rights and the public health. We trust, for the sake of common decency, that these charges will prove unfounded. If the defendants are found guilty, however, then the public has a right to expect that full justice will be done to it.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

HOUSSAY, BERNARDO A. Professor of Physiology, Faculty of Veterinary Medicine, University of Buenos Aires, 1910. M.D. Faculty of Medicine, University of Buenos Aires 1911. Professor of Physiology, Faculty of Medical Sciences, University of Buenos Aires 1919. His subject is What We Have Learned from the Toad Concerning Hypophyseal Functions. Page 913. Address: University of Buenos Aires, Buenos Aires, Argentina, S. A.

SCHUBE, PURCELL G. B.A., B.M., M.D. University of Cincinnati College of Medicine 1929. Formerly, Intern, Cincinnati General Hospital. Resident, Good Samaritan Hospital. Fellow, Neuropsychiatry, Colorado Psychopathic Hospital, Denver, Colo. Assistant Physician, Neuropsychiatric Institute and Hospital, Hartford Retreat, Hartford, Conn. Now, Physician in Charge, Psychiatric Clinic, Boston State Hospital. His subject is A Study of the Use of Cocaine in Dealing with the Effects of Barbiturate Acid Derivatives. Page 926. Address: Boston State Hospital, Dorchester Centre, Mass.

ROTHSCHILD, DAVID. B.Sc., M.D. McGill University, Faculty of Medicine 1922. Senior Physician and Director of Research, Foxborough State Hospital. Consulting Neuropsychiatrist, Brockton Hospital, Brockton, Mass. Address: Foxborough State Hospital, Foxborough, Mass. Associated with him is

SHARP, MORRIS L. M.D. Tufts College Medical School 1932. Junior Assistant Physician, Foxborough State Hospital. Address: Foxborough State Hospital, Foxborough, Mass. Their subject is Frequency of Active Tuberculosis in a Hospital for Mental Diseases. Page 929.

LITTLE, RUFUS R. A.B., M.D. University of Pennsylvania Medical School 1930. Assistant Physician, North Reading State Sanatorium. His subject is Congenital Defect of the Pectoral Muscles. Page 934. Address: North Reading State Sanatorium, North Reading, Mass.

CORRIDEN, THOMAS F. M.D. University of Vermont College of Medicine 1920. F.A.C.S. Consultant in Surgery, Veterans Administration Facility Hospital, Northampton, Mass., No. 95, and Northampton State Hospital. Surgeon, Cooley Dickinson Hospital, Northampton, Mass. His subject is Acute, Ulcerative, Terminal Ileitis and Colitis. Page 936. Address: 16 Center Street, Northampton, Mass.

BREECH DELIVERY 2

The operation of breech extraction bears the same relation to a breech presentation as does forceps delivery to a vertex presentation and has, in strict interpretation the same indications, e.g., conditions which demand prompt termination of labor in the interest of either mother or child. As with forceps delivery breech extraction should be carried out only

1 When there is no disproportion between the infant and the maternal pelvis

2 When the os is fully dilated in relation to the presenting part, and the membranes have ruptured spontaneously or have been ruptured as a preliminary step

3 When the patient is under the influence of full anesthesia.

4 When adequately trained assistance is at hand

Since the details of these conditions have been considered in the previous section of the communication it remains only to discuss the technique of extraction, which, save in the matter of the management of the submechanism of the breech, is identical in frank, full and footling presentations.

1 Under full anesthesia and with the vulva and perineum aseptically prepared the feet of the infant should be grasped. This step is simple in the full and double footling presentations, as the feet are low in the birth canal and may even be at the vulva. In frank breech presentations, where the hips are flexed and the knees extended the feet should be secured by the Pinard maneuver. To do this the perineum should first be dilated until the entire hand can be passed into the vagina. The right hand should be selected when the baby's back lies to the mother's right (RSA and RSP positions) the left when the position is LSA or LSP. In each case the palm of the hand inserted will face the infant's belly and the posterior aspect of its thighs. By making pressure on the posterior aspect of the thigh thereby hyperflexing the hip and tensing the hamstring muscles, the leg will flex at the knee and the foot will prolapse

within the grasp of the hand. It is well in this step to bear the following points in mind

a The breech must be pushed up above the pelvic brim in order to make room for the maneuver

b The umbilical cord will usually be felt and if wrapped around a leg or if between the legs, should be disengaged and displaced upward out of the way

c. The maneuver should be carried out between uterine contractions

d Each step should be effected methodically and without haste

e Both legs should be secured

In angle footling presentations where the anterior foot is prolapsed, it is not essential to flex out the posterior leg. When however the posterior foot presents it is better judgment in all cases to secure the anterior by the method above described, as attempts to deliver a breech by traction only on the posterior leg may result in delay due to the tendency of the infant to straddle the maternal symphysis

2 After both feet have been secured traction should be made on both of them obliquely downward toward the floor exerting moderate pressure on the perineum. The use of a sterile towel to grasp the feet will provide a secure grip. As the knees appear the grip should be shifted upward on the legs thence upward to the lower thighs after the knees are born. The anterior hip of the infant will be rotated to the pubic arch by the resistance of the pelvic floor and will soon be identified beneath the pubis. Traction upward will now deliver the posterior hip over the perineum

3 Shifting the grip upward to grasp the hips traction is now continued obliquely downward rotating the baby's back upward and keeping it upward until time for delivery of the shoulders, for by so doing the shoulders are brought into relation with the widest transverse diameter of the pelvic inlet through which they are about to pass. As the umbilicus passes over the perineum the cord should be pulled down several inches from above in order to allow slack for the balance of the delivery

4 No attempt should be made to deliver the shoulders or arms until the scapulae can be either seen or definitely palpated beneath the arch. The grip is then shifted upward to embrace the thorax of the baby and the anterior shoulder is rotated ninety degrees to the arch keeping the body well downward against the perineum. Usually the arm will be found well flexed alongside the thorax and the elbow is swept out by the operator passing two fingers over the shoulder fixing the tips in the antehumeral region and splinting the humerus,

A series of short selected articles by members of the Section is being published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the Section.

as he presses with the digital phalanges. The infant is now rotated one hundred and eighty degrees on its long axis, keeping the back uppermost, one hand over the delivered shoulder, and the other on the opposite side of the thorax to effect rotation, the shoulder which was originally posterior is now anterior, and the arm is delivered as above described.

Should the anterior shoulder prove to have an extended arm, attempts to deliver the latter should be postponed. The posterior shoulder should be made anterior without delay, the act of rotating serving to wipe the arm, if originally extended, down across the face, the shoulder originally anterior, now posterior, is again made anterior, when it will be found to have been also wiped down across the face and to lie alongside the thorax. *At no time during rotation should traction be made, and at all times the back should be kept uppermost.*

5 The arms once delivered, the towel used for traction should at once be discarded. For a right (left) handed operator the infant should be now laid face downward astride his left (right) forearm. The index and middle fingers of his left (right) hand are passed into the vagina and into the mouth of the infant to be used to guide the chin over the perineum. The right (left) palm seeks the cephalic prominence above the symphysis and steadily presses the baby's occiput into the pelvis, while the left (right) arm raises the body upward over the pubic region. This maneuver suffices to flex the head over the perineum in most multiparae, should it not suffice, a deep mediolateral episiotomy should be done without delay, a step which should be the rule with a primiparous breech extraction. If, despite this, the head does not descend and flex easily, the baby's feet and legs should be grasped in a sterile towel by an assistant and the body held high in front of the vulva, no time should then be lost in application of forceps to the aftercoming head and flexion by this means over the perineum.

Considerations of space do not permit an extended discussion of the pathological aspects of breech delivery. Sufficient has been described, however, to indicate that a successful outcome of this type of labor must be predicated upon the principle of eternal study and vigilance, and upon judgment and operative ability which can be acquired only by training and experience.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning May 10

Berkshire

Thursday, May 14, at 4 30 P M., at the House of Mercy Hospital, Pittsfield Subject

Lung Diseases (Medical) — (a), Differential Diagnosis and Treatment of Lobar Pneumonia (b) Symptoms and Signs in Chronic Lung Disease, Tuberculosis, Bronchiectasis, etc. Instructor S H Proger. Melvin H Walker, Jr, Chairman

Bristol North

Wednesday, May 13, at 7 30 P M., at the Morton Hospital, Taunton Subject Medical Economics Instructor C Frothingham. Arthur R Crandell, Chairman

Bristol South (New Bedford Section)

Friday, May 15, at 4 00 P M., at the St Luke's Hospital, New Bedford Subject Syphilis and Gonorrhea — Syphilis Modern Treatment The Use of Neosalvarsan, Tryparsamid, Bismuth, Mercury, Potassium Iodide, etc, in Office Practice Gonorrhea Treatment of Complications as Seen in General Practice Instructors A. W Cheever and N A Nelson. Harold E Perry, Chairman

Franklin

Wednesday, May 13, at 8 00 P M., at the Franklin County Public Hospital, Greenfield. Subject Psychiatry — Psychobiology in General Medicine Instructor K J Tillotson. Halbert G Stetson, Chairman

Middlesex East

Wednesday, May 13, at 4 00 P M., at the Melrose Hospital, Melrose Subject Diseases of the Liver—Hepatitis and Painless Jaundice. Problems in Diagnosis and Treatment. Instructor C M Jones. Joseph H Fay, Chairman

Middlesex North

Friday, May 15, at 7 00 P M., at the Lowell General Hospital, Lowell Subject Lung Diseases — (a) Significance of Symptoms and Signs in Chronic Lung Disease, Tuberculosis, Bronchiectasis, etc (b) The Value of Surgery in Above Disease Problems. Instructors H F Newton and D S King. Leonard C Dursthoff, Chairman

Norfolk

Friday, May 15, at 8 30 P M., at the Norwood Hospital, Norwood Subject Pediatrics (Surgical)—Abdominal Disease in Childhood Instructor H W Hudson, Jr. H B C Riemer, Chairman

Worcester (Milford Section)

Wednesday, May 13, at 8 30 P M., at the Milford Hospital, Milford, Subject Ophthalmology and Otolaryngology—(a) The Major Hazards in Diagnosis of Disease of the Eye, Ear, Nose and Throat as Seen in General Practice (b) Special Treatment in Acute Medical and Traumatic Diseases of the Eye Emergencies Arising in the Treatment of the Ear, Nose and Throat. Instructors T Gundersen and F L Weille. Joseph I Ashkins, Sub-Chairman

MASSACHUSETTS LEGISLATIVE
NOTES

House 24 has been amended under House 120 by striking out all after the enacting clause and inserting in place thereof the following (which includes the recommendation of His Excellency the Governor) —

"SECTION 1 Section two of chapter one hundred and twelve of the General Laws is hereby amended by striking out the second sentence, as appearing in section one of chapter one hundred and seventy one of the acts of nineteen hundred and thirty three and inserting in place thereof the following —

"Each applicant who shall furnish the board with satisfactory proof that he is twenty-one or over and of good moral character that he possesses the educational qualifications required for graduation from a public high school, that he has completed two years of pre-medical collegiate work including physics chemistry and biology in a college or university approved by a body consisting of the secretary of the board, the commissioner of education and the commissioner of public health, in this section referred to as the approving authority that he has attended courses of instruction for four years of not less than thirty-two school weeks in one or more years or courses which in the opinion of the board are equivalent thereto in one or more legally chartered medical schools and that he has received the degree of doctor of medicine or its equivalent, from a legally chartered medical school having the power to confer degrees in medicine and approved by the approving authority shall, upon payment of twenty-five dollars, be examined, and if found qualified by the board, be registered as a qualified physician and entitled to a certificate in testimony thereof signed by the chairman and secretary. An applicant aggrieved by the refusal of the approving authority to approve a medical school under this section shall be entitled to have the reasonableness of such refusal reviewed by a justice of the superior court whose decision shall be final.

"SECTION 2. Said section two of said chapter one hundred and twelve, as amended, is hereby further amended by adding at the end thereof the following three new paragraphs —

"The approving authority shall upon the request of any college university or medical school in this commonwealth inspect said college university or medical school and notify its trustees or other governing body in writing if said college, university or medical school is approved by the approving authority for the purposes of this section or if not, what steps said college university or medical school must take in order to gain the approval of the approving authority

"Any college university or medical school desiring to be approved for the purposes of this section may file with the approving authority a written request for the approval of such college, university or medical school and thereupon a public hearing shall be seasonably granted by the approving authority and

a written decision made by it within twenty days after the termination of such hearing and the applicant for such approval shall be notified of such decision. A written decision of the approving authority refusing to approve any college university or medical school shall not become effective until thirty days after written notice of such decision is given to the college university or medical school seeking such approval. Every such college university or medical school aggrieved by such refusal shall have the right to file a petition in the superior court for Suffolk county to revise or reverse the decision of the approving authority. Notice of the entry of such petition shall be given to the secretary of the board of registration in medicine and all proceedings connected therewith shall be according to rules regulating the trial of civil causes without juries. The court shall hear the case and finally determine whether or not such approval shall be granted or revised.

Upon the filing of such a petition within the aforesaid period of thirty days then the said decision of the approving authority shall not become effective until a final decree affirming said decision is entered upon the aforesaid petition.

"SECTION 3 The provisions of said section two of said chapter one hundred and twelve as existing immediately prior to January first, nineteen hundred and thirty-nine shall continue to govern as to the eligibility of any applicant for registration as a qualified physician who shall have matriculated prior to said date in any legally chartered medical school having power to confer degrees in medicine but subject, however to the provisions of section two of chapter one hundred and seventy-one of the acts of nineteen hundred and thirty-three.

"SECTION 4 For purposes of examination and registration of applicants and of approval of medical schools osteopathic schools recognized by the American Osteopathic Association shall have the same standing before the board of registration in medicine, and the approving authority provided for in section one as medical schools recognized by the American Medical Association.

"SECTION 5 The approving authority provided for in section one shall within three months after the effective date of this section publish the qualifications that said authority will require of a college university or medical school in order that it be approved under section one.

"SECTION 6 The provisions of this act providing new eligibility requirements for applicants for registration as qualified physicians shall become effective January first, nineteen hundred and thirty-nine."

HOUSE 1759

Reported on Senate 321. A new draft as below
Resolve reviving and continuing the special commission on public health laws and policies

Resolved, That the unpaid special commission established under chapter eleven of the resolves of

nineteen hundred and thirty-five, for the purpose of studying and investigating the public health laws and policies of the commonwealth, is hereby revived and continued, and said commission is hereby directed to study the subject matter of the House resolve printed as Senate document number three hundred and twenty one of the acts of the current year relative to construction of a new hospital for the treatment of infantile paralysis and arthritis. The final report of said commission shall be filed with the clerk of the House of Representatives on or before the first Wednesday of December in the current year.

Senate 24 April 29 Report leave to withdraw Accepted in Senate (Final) The bill was designed to abolish the several Boards of Trustees of institutions in the departments of Mental Diseases and Public Welfare

MISCELLANY

CONNECTICUT NEWS

The Fairfield County Medical Association held its 144th annual meeting in Bridgeport on Tuesday, April 14, 1936. At this meeting the following officers were elected for the year 1936-37:

President—John Shea, M.D., Bridgeport
Vice-President—John H. Staub, M.D., Stamford
Secretary—R. Harold Lockhart, M.D., Bridgeport
Treasurer—Clifton C. Taylor, M.D., Bridgeport
Councilors—James D. Goid, M.D., Bridgeport

After an active business session the members were addressed by Dr. Walter S. Lillie, Professor of Ophthalmology, Temple University, on "Ophthalmological Changes Produced by Intracranial Lesions," and by Dr. Temple Fay, Professor of Neurological Surgery, Temple University, on "The Diagnosis of Cerebral Tumors."

Dr. Harry L. F. Locke has been appointed chairman of a special committee of the health division of the Hartford Chamber of Commerce which will direct participation for the third year in National Child Health Week. During this Child Health Week, an outgrowth of the dedication by Herbert Hoover, while president, of May 7 to better and healthier children, the care of the teeth will be stressed.

The health committee has pledged support to a dental health program initiated by the State Department of Health and to the plan of the local Department of Health for a campaign during May to immunize preschool children against diphtheria.

In 1933 the Chamber of Commerce endorsed the first Oral Hygiene program conducted by the Hartford Dental Society during Child Health Week. This present campaign will point out the value of dental care by means of posters and talks.

The special commission created by the last session of the General Assembly to study and inquire into the present financial responsibility act of Con-

necticut, with the purpose of suggesting alterations, amendments, or revisions of the act, has been sitting almost weekly since August, 1935. Suggestions have been solicited from many groups of citizens whose activities the present financial responsibility law has in some manner or form touched or controlled. Corouers, hospital managers, doctors, welfare administrators, officials of the State of Massachusetts, casualty company executives all these and many more have been consulted and the suggestions offered run the whole distance from the proponents of the compulsory insurance idea down to the proponents of the theory of more restricted issuance of registrations and licenses to drivers.

That the topic is a timely one and that the conclusions of the committee will be awaited with interest is manifest on all sides. The State of New York has recently had a commission studying the same or similar subjects, various other commonwealths of the country are canvassing the situation and within the past ten days the State of Maine appointed a commission to study the problem.

There is a tendency in many states to pattern their laws after the Connecticut Responsibility Act and there is a feeling that Connecticut's contribution to the present discussion will bear considerable weight.

MENTAL HOSPITALS AND THE PUBLIC

The present relationship between the mental hospital and the community holds much that is fundamentally wrong, according to Dr. C. C. Burlingame, Psychiatrist in Chief of the Neuropsychiatric Institute of the Hartford Retreat. "This basic relationship will have to be changed before a better order of things can come. We, as workers in the field, have been too willing to remain as little isolated patches, or, may I say, detached artificial communities within a civilization of which, to a surprising degree, we have failed to be a real part."

"As a corollary, I might well indict the social order which continues to expect to solve the great problem of mental and nervous illness and yet allow the mental hospital to remain in such an isolated, detached relationship to the remainder of the present-day social structure and body politic."

"Those responsible for mental institutional care cry out against the indifference on the part of the public, against low appropriations, against the indifference to the sufferer from mental illness as opposed to the generosity to the sufferer from physical illness."

"In other words, the hospital for mental illness must not be a negative symbol of defeat from which people turn away in distaste, it must be a positive force in the community, exercising, in an ever widening sphere of influence for constructive good, a medium for the dissemination of education and a potent factor in breaking down the age-old prejudices against diseases of the mind."

Dr. Burlingame in his annual report emphasized the growth of the Neuropsychiatric Institute during

the past five years told how it had passed into the most active preventive and therapeutic field, but what should and does give us the greatest satisfaction is the fact that we have retained a far greater number of people to society who have benefited by their stay.

We must make mental hospitals more normal, conduct them more normally and more closely simulate appearances, practices and the division of responsibility that obtains in the community at large.

It is an undeveloped state of mind in the public which has created literally thousands of endowed general hospitals, backed by private philanthropy and lavish charity, while but a handful of endowed institutions are providing care for mental and nervous cases. That must be changed.

"The general hospitals have a perfect army of friends who come forward and tell of their experiences and express their gratitude but the mental hospital most often hears only from the paranoid, the disgruntled and the self-seeking as the army of those who have been helped during a nervous and mental illness still hesitate to come forward because they fear unenlightened public opinion and believe that revealing the fact that they have been in a mental hospital is tantamount to dragging the family skeleton from the closet.

THE NEGRO TUBERCULOSIS DEATH RATE IN HARTFORD

The death rate from tuberculosis in Hartford has dropped sharply during the past fifty years but this decrease has taken place almost entirely among the white population. The white death rate from tuberculosis was ten times as high fifty years ago as it is now. The present colored death rate from tuberculosis however is as high as the white rate was fifty years ago and is now ten times as high as the present white rate. While the colored population of Hartford is only about four per cent of the total it accounts for twenty-nine per cent of the tuberculosis deaths.

Fifty years ago the death rate from tuberculosis in Hartford was 365 per 100,000 population. In 1935 it was white 32, colored 363 per 100,000. New Haven for 1935 showed a tuberculosis death rate of white 43, colored 105 per 100,000 population.

In Detroit the colored tuberculosis death rate was reduced from 355 in 1915 to 248 in 1935 chiefly through a program conducted by the colored people. The Detroit Health Bulletin describes this program thus: "While it is true that the colored rate is about six times as high as that of the white group there is a commendable spirit among the colored people of Detroit to do everything possible to prevent the spread of infection among their people. Several colored physicians have taken special courses to make themselves proficient in the treatment of tuberculosis and several private hospitals have been established for the care of their afflicted. There has been established an organization among the colored people to promote sanitary living conditions

and to encourage the physical examination of all those who give symptoms suspicious of tuberculosis.

SUCCESS IN BOVINE TUBERCULOSIS ERADICATION PROGRAM

After seventeen years of effort Connecticut has become a modified accredited area in the bovine tuberculosis eradication program. The announcement which recently came from Washington means that on the last test less than one-half of one per cent of the cattle in the state reacted positively. This campaign to drive tuberculosis from Connecticut dairy herds has cost \$3,250,000. Ninety thousand cattle equal to one-half the normal cattle population of the state, have been condemned and slaughtered. The completion of this task was made possible by an emergency appropriation of \$150,000 granted by the 1935 General Assembly and by additional funds made available through the Agricultural Adjustment Administration at Washington. Since the beginning of this campaign in 1919 Connecticut has spent for indemnities roughly \$2,000,000. The Federal Government has contributed about \$1,250,000.

Connecticut now becomes the thirty-ninth state in the country to qualify as a modified accredited area. The last of the New England States except Rhode Island. Its task was more difficult than many other states since it was considered the most heavily infected state in the country with an average percentage of infection considered conservatively at thirty per cent. As neighboring states made more rapid progress in the early years of the campaign and as rules grew stricter elsewhere tuberculous cattle were shipped into Connecticut until it became a dumping ground of the unfit.

Hartford County several years ago became the first accredited area in the state, testing in this county being stimulated by the insistence of the Hartford (City) Board of Health that milk must come from tested herds. Tolland and Middlesex Counties followed, then Windham and Litchfield Counties. Within the past few weeks New London, New Haven and Fairfield Counties qualified. All dairy herds within the state are under supervision. If there has been a reactor in the herd at the last test, the herd is tested again in ninety days. Herds without reactors are tested once a year. In every case reactors are condemned and slaughtered.

FLOOD CONDITIONS IN THE HOSPITALS OF HARTFORD

A survey of the four largest hospitals in Hartford since the subidence of the Connecticut River revealed the fact that varying conditions existed. St. Francis Hospital probably suffered the least since it was without electricity from the plant supplying the city only one night, and during this time it used its own emergency lighting system. The operating room schedule was not curtailed. At the other extreme was Mt. Sinai Hospital with no electric power for six days after which time it secured current from its own generator installed for the duration of

the emergency, five more days. It was necessary to operate by candle and flashlights.

The Municipal Hospital received no electric power from the usual supply for seventy-two hours, and during this time had no heat. The emergency unit supplied sufficient light to carry on work but only emergency operating was permitted. The Hartford Hospital, the largest in the city, was not dependent on electricity for its heat. It was necessary, however, to use its own electric generating plant for an entire week since this was more reliable although it supplied but one-half the usual load to the hospital. At times the hospital would switch back to the crippled city supply for a few hours at night. Only emergency surgery was done during this period.

ANNUAL MEETING OF HARTFORD COUNTY MEDICAL ASSOCIATION

The 144th annual meeting of the Hartford County Medical Association was held in Hartford on the afternoon and evening of April 7, 1936. The afternoon session, opening at 4:30, was concerned chiefly with the reports of officers and committees. Of particular interest among the latter was a report by Dr. Henry N. Costello in which was presented a review of medical legislation in the Connecticut General Assembly from 1919 to 1935. This supplemented a similar report given by the same chairman one year ago in which the period 1911 to 1919 was covered. The afternoon session closed with a résumé of the achievements of the Committee on Tumor Study of the Connecticut Medical Society by its chairman, Dr. Thomas H. Russell of New Haven.

One hundred and fifteen convened at the Hartford Club for dinner. Dr. Arthur B. Landry, retiring president of the Association, presented an excellent paper on "Unfinished Business." Honorable Newell Jennings, Judge of the Superior Court of Hartford County, spoke very entertainingly on "Expert Medical Testimony." Dr. Stephen Rushmore of Boston, guest at the dinner, briefly discussed Judge Jennings' paper.

Thirteen new members were elected to the Association bringing the total membership to 472.

The following were elected to office:

President, Ralph A. Richardson, M.D., Bristol, Vice-President, Maurice T. Root, M.D., West Hartford, Secretary-Treasurer, Stanley B. Weld, M.D., Hartford.

Member of Board of Censors for 3 years, Arthur B. Landry, M.D., Hartford.

Member of Committee on Public Policy and Legislation for 2 years, Aaron T. Pratt, M.D., Windsor.

State Delegates for 3 years, Vincent Mendillo, M.D., New Britain, D. C. Y. Moore, M.D., South Manchester, and William Hanrahan, M.D., Bristol.

THE ADDRESS ON "EXPERT MEDICAL TESTIMONY," BY
HONORABLE NEWELL JENNINGS, JUDGE OF THE SUPERIOR COURT OF HARTFORD COUNTY

Judge Jennings prefaced his remarks by saying that in looking around for material on this subject

he could find very little, in fact there was but one text on the subject in the combined State and County Bar libraries. This was by Lawson and too dry to be readable. He divided his subject into two parts, first, testimony as to fact, and secondly, opinion testimony. Facts are very important in the trial of cases. The physician called to testify cannot help the court and his clients any better than by having a clear grasp of the facts. Medical testimony differs from no other testimony offered in court other than it is given by a physician in the practice of his profession. Testimony as to fact is from observation and is not subject to dispute. The physician's language in court should be simple and couched in such terms that the jury and judge can readily understand. It is important for the physician to remember that he should use plain everyday English in the sense it is used by the jurymen and the lay judge. Many physicians' statements have to be translated. This is necessary because his opinion is based on the facts. The facts presented should be accurate and to this end it is of inestimable value that the physician have his records with him.

Opinion testimony, on the other hand, is not permissible in our United States system of jurisprudence but is admitted as a matter of necessity. This is evident in a situation where the facts have been presented to the jury and the jury, in turn, because of its limited knowledge, has no way of forming an opinion. In such a situation the opinion of an expert is allowed.

Opinion testimony may be based on observation or fact, or it may be based on hypothesis. Opinion testimony based on observation is the usual and most important form. According to Lawson, expert medical testimony was formerly as a rule based on hypothetical facts but this is no longer true. Now the most important testimony is based on actual observation. True, two men may look at the same phenomenon and derive therefrom different opinions. The controversy usually arises between the family physician who has had more and longer opportunities of observation of a case and the physician called in by the defendant to testify after making one or two examinations. Juries are often confused but there is nothing more fatal to the trial of a case than to have the jury discover it has been misled. The differences in the opinions between physicians are usually not striking except in mental cases. This is due to the different theories pertaining to mental science, also to the differences between the medical and legal definitions of sanity. Mentally we all differ from the norm in the psychiatrist's eyes but legally there is no such difference, only sanity and insanity. The jury pays attention only to the facts.

Opinion testimony based on hypothesis is not so important as formerly. It was formerly a long drawn out affair met, if possible, by more numerous and more tedious objections. At present it has fallen into disuse. There are certain kinds of hypotheses which are of value and arise when opportunities for observation have not been satisfactory.

In closing Judge Jennings referred to the question of a physician's qualification. Many through false or real modesty make it necessary to have dragged out of them their qualifications. The value of a physician's opinion depends on facts and one of the facts is the statement as to his own education and preparation. The most important qualification of the doctor is honesty. About eighty per cent of cases are settled out of court, the remainder are tried because of a difference of opinion. His final plea to the profession was for a clear presentation of facts in English that could be understood not too concise but full and complete.

THE SIXTY-FOURTH ANNUAL REPORT OF THE HARTFORD DISPENSARY

In this document the largest item of income is \$29,840.89 contributed by the Hartford Community Chest which together with the payments of patients of \$8,093.95, fees by the laity and income of endowments, make a total income of \$42,249.46. The disbursements were of an equal amount.

The report of Dr. Stanley B. Weld, Physician in Chief, showed that 33,938 treatments were furnished during 1935 as compared with 38,564 in 1934.

The cost per treatment increased from seventy-six cents to one dollar. The number of clinics has increased to twenty-eight.

MIDDLESEX COUNTY MEDICAL ASSOCIATION

At the annual meeting of the Middlesex County Medical Association held at the Edgewood Country Club Cromwell Thursday April 9, 1936 the following officers were elected:

President, Louis O. LaBella, M.D. Vice-President, Harold M. Speight, M.D. Secretary-Treasurer, G. Mansfield Craig, M.D.

Guest speakers were Philip Woodbridge, M.D., and Samuel A. Marshall, M.D., both from the Lahey Clinic, Boston.

APPOINTMENT OF DR. LABELLA

On April 6, 1936 Dr. Louis O. LaBella was appointed Health Officer for the city of Middletown.

APPOINTMENTS IN THE HARVARD MEDICAL SCHOOL

The following Harvard Medical School appointments for the year beginning September 1, 1936 have been announced:

HUNTINGTON MEMORIAL HOSPITAL

Ernest Merrill Deland—Consulting Surgeon.
Varastad Hovanness Kazanjian—Consulting Surgeon (Plastic Surgery).
George Adams Leland, Jr.—Surgeon.
Charles Carroll Lund—Surgeon.
George Olbert Smith—Surgeon (Gentle-Urinary).

Grantley Walder Taylor—Surgeon.

Joe Vincent Meigs—Associate Surgeon.

Fletcher Hatch Colby—Assistant Surgeon (Gentle-Urinary).

Charles Longdon Parsons—Assistant Surgeon.

Charles Louis Swan, Jr.—Assistant Surgeon.

Arthur Moses Greenwood—Dermatologist.

Clarence Guy Lane—Dermatologist.

Edwarda Woodbridge Herman—Laryngologist.

Leroy Allen Schall—Assistant Laryngologist.

Slimeon Burt Wolbach—Consulting Pathologist to the Cancer Commission.

Shields Warren—Pathologist to the Cancer Commission and to the Huntington Hospital.

Olive Gates—Assistant Pathologist to the Cancer Commission and to Huntington Hospital.

Merrill Clary Sosman—Consulting Roentgenologist.

Richard Dresser—Roentgenologist.

William Thomas Salter—Associate Physician to the Huntington Hospital and Research Fellow in Biological Chemistry to the Cancer Commission.

Francis Tennery Hunter—Associate Physician.

Henry Jackson, Jr.—Associate Physician.

Austin Moore Brues—Assistant Physician.

John Alfred Calhoun, Jr.—Assistant Physician.

Paul Charles Zamecnik—Resident Physician.

Ira Theodore Nathanson—Lucius Littauer Fellow.

Clark Edward Brown—Lucius Littauer Fellow.

George Herbert Hitchings—Research Fellow.

Robert Harold Oster—Research Fellow.

Joseph Briggs Howland—Administrator.

CANCER COMMISSION

James Bryant Conant, Chairman. Charles Briggs

Howland, Secretary. Charles Sidney Burwell,

Elliot Proctor Joslin, Edwin Bidwell Wilson,

Slimeon Burt Wolbach, Robert Battey Green

ough, Channing Chamberlain, Simmons, Ernest

Edward Tyxer, Lawrence Joseph Henderson,

Hans Zinsser, George Richards Minot, Joseph

Charles Aub, William John Crozier.

ADVISORY BOARD

James Bryant Conant, Chairman. Charles Jackson

Treasurer. William Perkins, Homans, Deputy

Treasurer. Joseph Briggs Howland, Secretary.

Charles Grey Bancroft, Robert Winsor, Jr., Al

fred Harlow Avery, Phillips Ketchum.

ADMINISTRATIVE COMMITTEE

Charles Sidney Burwell, Chairman. Joseph Briggs

Howland, Secretary. Lawrence Joseph Hender

son, Joseph Charles Aub.

THE APPOINTMENT OF DR. FRANK FREMONT SMITH

Dr. Frank Fremont Smith, until recently Assistant Professor of Neuropathology at the Harvard Medical School, and Associate Psychiatrist at the Massachusetts General Hospital, was appointed on February 1, 1936, to the staff of the Josiah Macy Jr. Foundation. Dr. Fremont-Smith will be in charge of the Medical Division to which he will give full time.

DR WILLIAM D. McFEE WILL ATTEND THE INTERNATIONAL CONGRESS OF PHYSICAL MEDICINE

Dr. William D. McFee will act as official delegate to the Sixth International Congress of Physical Medicine and Physiotherapy in London, May 12 to 16 representing the Public Health Service of the United States, his appointment having been authorized by President Roosevelt. He will also be the official delegate of the Academy of Physical Medicine and of the New England Physical Therapy Society.

At the Section on Electrotherapy Dr. McFee will present a report on the Present Status of Fever Therapy in the United States by Dr. McFee and Dr. Hosea W. McAdoo.

Dr. McFee has served as Vice-President of the International Association of Physical Medicine and Physiotherapy since his election at the Congress in Liege, Belgium, in 1930.

PHYSICIANS' ART EXHIBITION

The following physicians contributed to the exhibition recently held at the Doll and Richards Galleries, 138 Newbury Street, Boston: E. P. Bagg, Lawrence W. Baker, J. Dellinger Barney, Robert M. Bell, Howard Coggeshall, Frederic J. Cotton, William P. Coues, John R. Graham, Lewis Webb Hill, James C. Janney, Arthur Bates Lyon, James H. Means, Harris P. Mosher, Claude L. Payzant, Hale Powers, Walter F. Sawyer, Somers H. Sturgis, Fritz B. Talbot, Nathan B. Talbot, G. W. Taylor, Sidney C. Wiggin and A. William Reggio.

ONLY ONE CASE OF TYPHOID FEVER REPORTED IN APRIL

According to alleged reports by Dr. Gaylord Anderson of the Massachusetts Department of Public Health, only one case of typhoid fever was reported in Massachusetts during April. That was in Waltham and outside the flood area.

MORTALITY RATES

Telegraphic returns from 86 cities with a total population of thirty-seven millions for the week ending April 18 indicate a mortality rate of 13.2 as against a rate of 12.3 for the corresponding week of last year. The highest rate (23.8) appears for Evansville, Ind., and the lowest (4.9) for Somerville, Mass. The highest infant mortality rate (13.9) appears for New Orleans, La., and the lowest for Cambridge, Mass., Duluth, Minn., Erie, Pa., Long Beach, Calif., Lowell and Lynn, Mass., and Waterbury, Conn., which reported no infant mortality.

The annual rate for 86 cities is 13.6 for the sixteen weeks of 1936, as against a rate of 12.6 for the corresponding period of the previous year.

SUMMARY OF MORTALITY FROM AUTOMOBILE ACCIDENTS

The Bureau of the Census announces that during the four weeks ending April 11, 1936, 86 large cities in the United States reported 567 deaths from automobile accidents. This number (567) compares with

630 deaths during the four weeks ending April 13, 1935. Most of these deaths were the result of accidents which occurred within the corporate limits of the city, although some accidents occurred outside of the city limits.

THE BOSTON PSYCHOANALYTIC INSTITUTE

A little more than fifteen years ago, the necessity for organized teaching according to academic standards, in the new and rapidly developing science of psychoanalysis, became manifest. It was this necessity for systematized training which, in 1920, instigated the establishment of the first Psychoanalytic Institute in Berlin. Previous to this, the usual method of teaching and learning psychoanalysis consisted essentially in undergoing a personal analysis by an experienced analyst. Following the original Berlin plan, there gradually evolved a systematized curriculum and training, supervised by training committees, who planned courses for accepted candidates and who designated certain analysts as qualified teachers. This systematic training consisted of supervised or controlled work with clinical cases and theoretical and clinical seminars, in addition to the personal analysis previously utilized.

As a result of these developments, training institutes were subsequently established in various European centers (London, Vienna, Paris, Budapest) and in the United States at New York (1931) and Chicago (1932). The Boston Psychoanalytic Institute, incorporated in Massachusetts, founded by the Boston Psychoanalytic Society in October, 1935, and under its supervision, is the third of such training institutes in American cities.

The aim of the Boston Psychoanalytic Institute is to provide a center of instruction in the field of psychoanalysis and related subjects for such properly qualified individuals as are selected by the Training Committee of the Boston Psychoanalytic Society. Among the future plans of the Institute are the establishment of a clinic for psychoanalytic treatment of patients with moderate means, systematic research in problems of clinical psychoanalysis and lectures for general practitioners.

The Institute is under the supervision of a Board of Trustees elected by the Boston Psychoanalytic Society, the majority of the members of this Board being selected from the Educational (Training) Committee of the Society. The trustees of the Institute are as follows: William Barrett, M.D., Isador H. Coriat, M.D., Leola Dalrymple, M.D., William Healey, M.D., M. Ralph Kaufman, M.D., John Murray, M.D., Martin W. Peck, M.D., Dr. Hanns Sachs and Dr. Helene Deutsch are members of the advisory board.

The activities of the Institute consist of lectures and clinical and theoretical seminars on psychoanalysis given to properly qualified individuals. Some of these courses and seminars are obligatory for all candidates in training. Among the courses offered are seminars on clinical psychoanalysis, technique, instincts, psychoanalytic psychiatry,

dream interpretation child analysis Freud's writings lectures on problems of adolescence, etc. The Institute thus offers a postgraduate training for physicians who wish to specialize in psychoanalysis and also gives opportunities for training in various nontherapeutic applications of analysis to those engaged in professional fields allied to medicine. The instruction at the Institute is given by training analysts who are appointed by the Educational Committee of the Boston Psychoanalytic Society. Admission to membership in the Society is open only to those who have satisfactorily completed the required training at the Boston or some other Institute which is recognized by the International Psychoanalytic Association.

Dr M. Ralph Kaufman, Riverbank Court Hotel Cambridge, Mass., is chairman of the Educational Committee to whom all inquiries should be addressed.

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MARCH 1936

Disease	Mar., 1936	Mar., 1935	5 yr. average*
Anterior Poliomyelitis	—	—	—
Chickenpox	1 137	1 149	1 14
Diphtheria	2	24	104
Dog Bite	677	716	395
Epidemic Cerebrospinal Meningitis	39	9	—
German Measles	816	5 120	1 16
Gonorrhea	485	51	—
Lobar Pneumonia	708	501	531
Measles	3 975	1 974	3 161
Mumps	2 477	532	81
Paratyphoid	1	—	—
Scarlet Fever	1 307	1 060	1 630
Syphilis	493	556	423
Tuberculosis Pulmonary	380	311	390
Tuberculosis, Other Forms	44	38	44
Typhoid Fever	5	6	7
Undulant Fever	4	3	—
Whooping Cough	399	777	1 164

Based on the figure for the preceding 5 years.

RARE DISEASES

Anthrax was reported from Lynn 1 August 1 total 2.

Diphtheria was reported from Boston 8 Bridgewater 2 Brockton, 1 Hanover 1 Lowell 3 Milbury 1 Newton 1 Quincy 1 Revere, 1 Somerville, 1 Waltham 1 West Bridgewater 1 total 22.

Encephalitis lethargica was reported from Boston, 1 Sangus, 1 total 2.

Epidemic cerebrospinal meningitis was reported from Ashland, 1 Belmont, 1 Boston 18 Bourne, 1 Bridgewater 4 Cambridge, 1 Dracut, 1 Easthampton 3 Hurl 1 Lincoln 1 Natick, 1 Quincy 1 Somerville, 2 Southboro, 1 Springfield, 1 Whitman, 1 total 39.

Pellagra was reported from Boston 1 Waltham 1 total, 2.

Septic sore throat was reported from Beverly 1 Boston 9 Concord 1 Danvers 1 Easthampton 1 Gardner 5 Georgetown, 1 Lynn 2 Malden 1 Melrose, 1 Petersham 4 Somerville, 1 total 28.

Trauma was reported from Boston 1 Cambridge 1 Milford, 1 total 3.

Trichinosis was reported from Boston 4.

Typhus was reported from Chelsea 1.

Undulant fever was reported from Ashby 1 Boston 1 Bourne 1 Conway 1 total, 4.

Diphtheria and pulmonary tuberculosis had their lowest reported March morbidity in the history of the State.

Epidemic cerebrospinal meningitis. Exclusive of twenty-two cases which occurred at two institutions the balance of seventeen is higher than for any March since 1930 with practically all sections of the State represented.

Undulant fever continues to be reported more frequently than in previous years.

Lobar pneumonia morbidity remained above the five-year average.

The incidence of typhoid fever to date is somewhat higher than in 1935 although the monthly figure fell below the previous year for the first time.

Since last August the reported incidence of mumps has been the maximum recorded for the State.

Scarlet fever morbidity is running above both the 1934 and 1935 figures but well below 1932 and 1933.

Whooping cough had its lowest reported March incidence since 1917.

The reported incidence of German measles remained higher than usual but not to compare with the epidemic figures of 1935.

The reporting of anterior poliomyelitis, chickenpox, measles, and tuberculosis other forms was not remarkable.

HEALTH OFFICERS MONTHLY STATEMENT OF VENEREAL DISEASES REPORTED IN NEW ENGLAND FOR FEBRUARY 1936

State	Syphilis		Gonorrhea	
	Cases Reported	Monthly Rate per 10 000 Population	Cases Reported	Monthly Rate per 10 000 Population

THE CERTIFICATION OF MASSACHUSETTS PSYCHIATRISTS

The American Board of Psychiatry and Neurology has certified a list of twenty-six Massachusetts physicians as qualified to practice this specialty. The list is as follows: Clarence A. Bonner, Ralph M. Chambers, Roderick B. Dexter, Lonnie O. Farrar, Winfred Overholser, Harlan Paine, Harry C. Solomon, Charles E. Thompson, Geneva Tryon, C. Macfie Campbell, James V. May, Joseph E. Barrett, Gaylord P. Coon, Frederick LeDrew, Jackson M. Thomas, David Rothschild, and Purcell G. Schube.

CORRESPONDENCE

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

535 North Dearborn Street, Chicago, Illinois,
May 1, 1936

New England Journal of Medicine,

In addition to the articles enumerated in our letter of April 1 the following have been accepted:

Cheplin Biological Laboratories, Inc.

Mercury Salicylate, 1 Grain (0.065 Gm.) Suspended in Oil, 1 cc.

National Drug Co.

Refined Tetanus Toxoid (Alum Precipitated)

Scientific Sugars Co.

Kinney's Cod Liver Oil Concentrate Capsules

Kinney's Cod Liver Oil Concentrate Liquid

G. D. Searle & Co.

Ampoules Bismuth Sodium Tartrate—Searle, 3 per cent, 2 cc.

Solution Bismuth Sodium Tartrate — Searle, 3 per cent, 60 cc. vial.

Sharp & Dohme, Inc.

Antipneumococcal Serum Types I and II

United States Standard Products Co.

Bismuth Salicylate in Oil

Scarlet Fever Streptococcus Toxin for the Dick Test

Winthrop Chemical Co., Inc.

Granules Protargol Compound

PAUL NICHOLAS LEECH, *Secretary,*

Council on Pharmacy and Chemistry

UNDULANT FEVER

A LETTER TO DOCTORS

The Commonwealth of Massachusetts
Department of Public Health
State House, Boston

April, 1936

During 1935, forty-two cases of undulant fever, one of which was fatal, were reported in Massachusetts. These cases occurred, with one or two exceptions, among users of raw milk, the cases being confined to those sections of the State where such milk is still sold. Unquestionably these figures, which are a

distinct increase over those of previous years, do not represent the total incidence of this disease which has become the principal milk borne infection in this State. Already in 1936 more cases have been reported than for the corresponding period of last year. Although the disease is rarely fatal, it is frequently extremely crippling, the patient being incapacitated for a period of months.

Such infections are usually contracted from the consumption of raw milk from infected herds. The only other source of infection is through contact with infected animals, this hazard being limited obviously to those whose occupation brings them into such contact. The prevention of the disease in animals is not yet possible, inasmuch as surveys of the State show a very high proportion of the cattle to be infected. If undulant fever is to be prevented, therefore, it is essential that all those milk supplies where pasteurization is feasible be so protected.

The united support of the medical profession is essential in any program toward improvement of the milk supplies. In some sections, however, there has been hesitation in recommending pasteurization because of a feeling that this procedure might impair the food value of the milk. This Department is not aware of any scientific evidence to support such a belief. Numerous studies have been made on this subject, all of which show an unimpaired food value. In order that some of this evidence may be brought before you so that you may form an independent opinion on the subject, the Department is sending herewith reprints regarding this subject and will send additional reprints when and as they are available.

Very truly yours,

HENRY D. CHADWICK, M.D.,
Commissioner of Public Health

EDITORIAL NOTE Enclosed with this letter were two reprints* by Leslie C. Frank and others of the United States Public Health Service emphasizing the food value of milk and the necessity of boiling or pasteurizing it in order to guarantee its safety.

*Frank, Leslie C. What every person should know about milk. Public Health Reports (Dec. 14) 1934.

*Frank, Leslie C., Clark, F. A., Haskell, W. H. et al. Do children who drink raw milk thrive better than children who drink pasteurized or other heated milk? Public Health Reports (Sept. 23) 1932.

RECENT DEATHS

KONIKOW—MOSES J. KONIKOW, M.D., of 726 Washington Street, Brookline, Massachusetts, died April 26, 1936. Dr. Konikow was born in Russia in 1868. After a preliminary education there and in Switzerland, he was given his M.D. degree by the University of Berne, Switzerland, in 1893, and came to Boston in the same year. He joined the Massachusetts Medical Society in 1894 and retired in 1933.

A widow, two sons and three daughters survive him.

REYNOLDS—JOHN TIMOTHY REYNOLDS, M.D. of Quincy Massachusetts died at the New England Baptist Hospital, Boston April 28 1936 after a short illness.

Dr Reynolds was born in Winchester Massachusetts the son of Mr and Mrs Richard Reynolds and after graduating from Holy Cross College studied at the Baltimore Medical College and received his M.D. degree in 1905.

He was the founder of the Reynolds Hospital in Quincy and was a Fellow of the Massachusetts Medical Society and the American Medical Association.

Three sons, Richard Reynolds of Washington John Reynolds Jr., and Lawrence Reynolds both of Quincy and four daughters Mrs. Margaret Blanch of Braintree Mrs. Eleanor Reilly of Milton and the Misses Barbara and Rosemary Reynolds, of Quincy survive him.

Mrs. Reynolds died two years ago.

MORRISON—ARCHIBALD BENJAMIN MORRISON, M.D. of 1493 Beacon Street, Brookline Massachusetts died at his home May 3, 1936 after an illness of two years.

Dr Morrison was born in Inverness County Nova Scotia, in 1864.

He graduated from the College of Physicians and Surgeons of Baltimore in 1906 and for the succeeding ten years served at the Boston City Hospital. While there he joined the Massachusetts Medical Society in 1906. After leaving the City Hospital Dr Morrison practiced in Deer Isle and Chatham, Maine, but after a few years returned to Massachusetts and located in Brookline.

His practice was confined to otolaryngology and ophthalmology.

Dr Morrison is survived by his widow Mrs. Currie E. (Brown) Morrison and a daughter Miss Enid Morrison.

NOTICES

STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

On Saturdays in the wards of the Peter Bent Brigham Hospital from 10 00 to 12 00 Staff Rounds will be conducted by Dr Henry A. Christian Physician in Chief Hersey Professor of the Theory and Practice of Physic at the Harvard Medical School. To these, practitioners and medical students are cordially invited.

SURGICAL LECTURES AT THE PETER BENT BRIGHAM HOSPITAL AMPHITHEATRE

Dr. H. H. Glertz, Surgeon-in-Chief Sabbatsbergs Sjukhus Stockholm Surgeon-in-Chief Pro Tempore Peter Bent Brigham Hospital.

May 18, 1936 Monday 2-4 P.M. Twenty Five Years of Experience in the Treatment of Peritonitis.

May 20 1936, Wednesday 2-4 P.M. Thrombo-Embolic Disease and Its Surgical Treatment

May 25 1936 Monday 2-4 P.M. Development of Respiratory Apparatus for Thoracic Surgery
All students and doctors will be welcome

TWO WORTHY INDIGENT PHYSICIANS

The sister of a reputable physician has notified this Journal of two elderly women physicians living together one a member of the Massachusetts Medical Society and the other a former member who were suffering for want of the comforts of life.

If anyone is interested in contributing money or food for these women, the facts are available at the office of this Journal.

HOSPITAL ADMINISTRATION

Dr Joseph C. Doane Medical Director of the Jewish Hospital Philadelphia, has arranged to give a short course in hospital operation this summer at Cornell University June 29 to July 11.

Students will devote all of their study time to hospital problems. The plan is to give executive instruction in the latest and generally endorsed methods for promoting efficient and economical administration of hospital problems.

Full information can be obtained on application to Professor Howard B. Meek of Cornell University Ithaca, New York.

REPORTS AND NOTICES OF MEETINGS

WORCESTER NORTH DISTRICT MEDICAL SOCIETY

The seventy-seventh annual meeting of the Worcester North District Medical Society was held at Burbank Hospital Wednesday April 22. Dr George P. Norton president, presided. The invocation was given by Rev. A. Vincent Bennett, rector of Christ Episcopal Church.

The annual election of officers resulted as follows: President Dr Sherman Perry Winchendon vice-president, Dr James F. Cuddy of Athol secretary Dr Francis M. McMurray treasurer Dr Frederick H. Thompson, Jr. conciliators Dr Thomas R. Donovan, Dr Richard A. Morgner Dr Harry R. Nye and Dr Charles J. Laserte both of Leominster and Dr Albert F. Lowell of Gardner censors supervisor Dr T. Donovan Dr Edward A. Adams Dr F. H. Thompson Jr., Dr Bartholomew P. Sweeney of Leominster Dr Alfred A. Wheeler of Leominster delegates for nomination of state officers Dr G. P. Norton alternate Dr John H. Kearney commissioner of trials Dr Nye of Leominster.

The report of the treasurer Dr F. H. Thompson Jr., showed a cash balance of \$308.20.

Among those present who spoke were Mayor Robert E. Greenwood who extended the greetings of the city Dr Howard M. Clute Boston surgeon and Richard Bullock superintendent of the hospital.

Dr Nye made a report of the committee on pub-

lic relations and Dr Frederick H Thompson, Sr, gave a résumé of the activities of the Fitchburg cancer clinic

The annual oration was delivered by Dr Clifford L Derick of Boston, associate professor at Harvard University and a nonresident consulting physician at Burbank Hospital His subject was "Staphylococcus Infection and Its Treatment"

A steak dinner was served by the hospital authorities and a rising vote of thanks was given to the superintendent and trustees of the hospital for the courtesy and facilities of the hospital for the meeting

Dr Norton in closing spoke of the pleasure he enjoyed as president during the past year and thanked the members for their attendance and assistance given him The secretary reported the deaths of two members during the year, Dr H W Ellam of Gardner and Dr Edward G Fosgate of Ashburnham

MASSACHUSETTS MEMORIAL HOSPITALS

There will be a luncheon meeting of the Surgical Section in the Aid Association Room, ground floor, Talbot Memorial, 82 East Concord Street, Boston on Friday, May 8, 1936, at 12 noon

"Massive Torsion of the Mesentery of the Small Intestine—A Case Report presented by Dr Ensio K F Ronka

Surgical deaths during April will be discussed
MIL0 C GREEN, M D, *Secretary*

THE SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the office of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, May 19, 1936, at 12 noon The speaker will be Howard B Sprague, M D, Assistant Physician, Massachusetts General Hospital Visiting Physician, House of the Good Samaritan, Assistant in Medicine, Harvard University Medical School, Courses for Graduates His subject will be Failure of the Circulation All physicians are cordially invited to attend Luncheon will be served at 1 o'clock

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance), Tuesday evening, May 12, at 8 15 P M

PROGRAM

Presentation of Cases

Development of the Cells of the Blood and Bone Marrow By Florence R Sablin, M D, Member, Rockefeller Institute for Medical Research, New York City

Medical students and physicians are cordially invited to attend

MARSHALL N FULTON, M D, *Secretary*

NORFOLK DISTRICT MEDICAL SOCIETY

EIGHTY SIXTH ANNUAL MEETING

The annual meeting of the Norfolk District Medical Society will be held at the Woodland Golf Club, West Newton, on May 12

ORDER OF EXERCISES

Business Meeting 7 00 P M

- 1 Minutes of Previous Meeting
- 2 Report of the Treasurer
- 3 Reports of Committees
- 4 Election of Officers
- 5 Incidental Business

Dinner 8 00 P M

Following the dinner there will be an Illustrated Lecture by Commander Donald B MacMillan, noted Arctic explorer

Commander MacMillan's lecture will be a general talk on the Arctic regions illustrated by means of both still and motion pictures It will include many of his unusual experiences with Peary in his polar expeditions as well as a wealth of material based upon his own expeditions in the exploration of these regions Commander MacMillan is an intensely interesting and able speaker and your Executive Committee urges you to make a special effort to attend

In accordance with our recent custom, members are invited to have ladies accompany them Dinner tickets for members will be \$1 50 and for their guests \$2 50 Please notify the secretary not later than Saturday, May 9, as dinner reservations must be made with the club management in advance

GOLF

Members are invited to enjoy the privileges of the links during the entire day

LEIGHTON F JOHNSON, M D, *President*,

FRANK S CRICKSHANK, M D, *Secretary*

1247 Beacon Street, Brookline

ESSEX SOUTH DISTRICT MEDICAL SOCIETY

The Annual Meeting of the Essex South District Medical Society will be held Wednesday, May 13, 1936, at the Salem Country Club

Dinner at 7 00 P M

Speaker Dr Paul White

Subject "A Medical Pilgrimage to Ancient Greece and Medieval Italy", with moving pictures

HANFORD CARVELL, M D, *President*

R E STONE, M D, *Secretary*

BOOK REVIEWS

From a Surgeon's Journal 1915-1918. Harvey Cushing. Boston. Little Brown and Company 555 pages \$5.00

This long-awaited diary covering March to May 1915 and March, 1917 to November 1918 will take its place as one of the outstanding books of the Great War. The author pre-eminent in the field of surgery made a distinct place for himself in literature with his "Life of Sir William Osler" published in 1915. He has now given us a glorious account of his war experiences in a day-by-day diary carefully recording the events he witnessed in his sojourn with the French Army and his longer stay with the British and American Expeditionary Forces.

In 1915 he spent three months with the Ambulance

has been measured and that have been published up to date, twenty-two were prepared and studied in our Institute^{1 2 48 49 50 53 54 55 117} The metabolism was diminished (average 16 per cent) in all except three, in which there was no decrease. These three dogs were the only ones which had a high columnar epithelium in the thyroid.

In the rat we found, like Collip, an average decrease of 24 per cent. In the toad no metabolic decrease occurred except when there was advanced asthenia*.

In hypophysectomized dogs there is thyroid insufficiency but not athyroidism because if the thyroid gland is removed there is a further metabolic decrease reaching to 24 per cent. On the other hand the metabolic decrease in thyroidectomized animals (average 24 per cent) is not modified by hypophysectomy.

Tubercular lesions caused a decrease in the metabolism in eleven of the twenty-two dogs studied up to date (eleven by Grafe and his collaborators, eleven in our Institute by Mazzocco,¹¹⁷ Solari¹³³). It is probable that in these cases, as in others, the tubercular lesion diminishes or inhibits the thyrotropic action of the anterior pituitary, but in several animals there was no atrophy of the thyroid epithelium. It is also possible that the tuber has a direct action on the pituitary or on other mechanisms.

A rise in metabolism occurs on injection of anterior pituitary extracts which have a thyrotropic action, the degree of rise depending on the species studied†. In the experiments of Artundo and Solari⁴ and Houssay and Artundo^{53 54 55} in both normal or hypophysectomized dogs there was a metabolic increase of between 28 and 62 per cent, accompanied by hyperactivity of the thyroid (high epithelium, liquefaction and reabsorption of colloid) and by signs of hyperfunction (tachycardia, polypnea, slight rise in temperature, loss of weight, polyuria). These phenomena do not occur if the injected animal is already thyroidectomized‡ although some animals have a slight metabolic increase and others a diminution.^{51 52 54}

We have not studied the habituation that is observed with prolonged treatment. In these cases a gradual decrease in metabolism which falls below the normal is seen and an antithyrotropic substance appears in the blood, (Anderson and Collip, Collip, etc.). In this connection it must be remembered that other anterior pituitary extracts depress metabolism (Falta, Verzar, Magistris, etc.).

The specific dynamic action in twenty hypoph-

*In other batrachians a decrease has been observed. Observations at different temperatures should be repeated.

†Biasotti by nasal insufflation of the acetone extracted powder of anterior pituitary lobe in some human cases obtained an increase in basal metabolism and polyuria. In others this result was not obtained.

‡Caro must be taken to verify that only the parathyroids remain and that no thyroid tissue has been left.

ysectomized dogs was found to be equal to that seen in normal animals^{1 2 55 117*}. There is a slight decrease in the specific dynamic action after thyroidectomy, which is more pronounced if the pituitary is also removed.⁵⁵

In conclusion the anterior pituitary has an indirect tonic action on basal metabolism, through its influence on the development and maintenance of the thyroid gland.

WATER METABOLISM

It is impossible even to mention all the complex problems presented by the physiological and pharmacological actions of the pituitary on different aspects of water metabolism so I will confine myself almost exclusively to the results of work done in our Institute.

Hypophysectomy almost always causes an intense polyuria† in dogs, rats and toads within a few hours of operation. This polyuria is transient in the great majority of dogs, and the rate of formation and the composition of the urine return to normal very soon,⁸⁸ possibly because the tubercular part remains. From the time of recovery from the initial polyuric stage, water administered is eliminated either with slight retardation^{81 82 83} or else normally (Refoizo, unpublished results).

Lesions of the tuber cinereum produce an intense polyuria which is frequently transient but at times permanent.^{38 73 98 99 130 131 140 144 166 178 179 181 194 254 313 421 etc.} This phenomenon seen by Aschner¹⁴⁰ and amply studied by Camus and Roussy^{178 179} has been confirmed many times in our Institute. Polyuria is observed only when the region in the neighborhood of the tuber cinereum is damaged. It does not occur if the lesion is produced outside this zone, as, for example, in the base (Houssay and collaborators, 1915-20) or in the dorsal surface of the brain¹⁰⁰ (Fig. 1). The polyuria occurs even when the pituitary appears to be histologically normal. This tubercular polyuria can be obtained experimentally in dogs,^{38 72 73 98 99 130 131} toads,^{80 124} sometimes in rabbits,³³ rats,³⁶⁹ pigeons^{371 372} and is also seen in man in cases with pathological changes.^{167 306 307 313 etc.}

The tubercular polyuria occurs in dogs with previously denervated kidneys^{72 99 144 175 01} after the splanchnics have been cut and the lumbar sympathetic chain extirpated¹³¹ and also when the liver and pancreas have been denervated (Rubio¹³¹).

There may be lesions in various of the hypothalamic nuclei in animals suffering from polyuria but the only constant lesions are those of the tubercular nuclei (Ramirez Coria,¹²⁶ confirming Camus, Gounay and Le Grand,¹⁷⁷ Gournay²⁴⁸).

*This statement is made without reference to what may occur in man since we have not studied the latter species.

†Confirmed by numerous workers since it was discovered by Vassallo and Sacchi¹²⁰ in the dog.

Polyuria usually precedes polydipsia and is seen even if the animal is deprived of water. The animals suffering from polyuria may be distinguished from the controls in water deprivation experiments by the fact that the diuresis is more prolonged, the density of the urine increases later and the blood becomes more concentrated.

Posterior lobe extract usually has an oliguric

its absence causes polyuria. When blood of a heart lung kidney preparation is diffused through the head of a dog it causes a decrease in polyuria and an increase in the elimination of chlorides. Perfusion through the pelvis and hind legs has no effect. If however the pituitary has been previously extirpated perfusion through the head also fails to check the polyuria.¹²⁹ Hypophysectomy in a few hours causes

FIG. 1

Drawing of a dog's brain showing the position of piqûre which resulted in diabetes insipidus, A and of those which did not alter the water metabolism in B and C.

action in normal animals^{11, 12, 80, 141, 175} and also in animals in which the kidneys have been denervated.^{79, 283} In certain conditions, however, it acts as a diuretic.^{41, 284, 285}

Posterior pituitary lobe extract diminishes or counteracts experimental or pathological polyuria insipida but its action is only transient, particularly if the polyuria is very intense (Houssay and Hug^{31, 32}).

The experiments of Verney¹ and Brall^{129, 170} favor the theory that a pituitary secretion physiologically modifies normal diuresis and that

polyuria and fall in chloride excretion which pituitrin corrects.¹⁴⁰ If the blood vessels of a kidney are united to those of a polyuric dog it secretes dilute urine but if the irrigation is changed for that of a dog with intact pituitary the kidney secretes more concentrated urine.^{1, 140}

It is therefore probable that tubular polyuria is to be attributed in great part to an inhibition of the kidney regulating secretion of the posterior pituitary.

The results we have obtained with toads in

our Institute are of great interest Polyuria may be produced in toads of the species *Bufo arenarum* Hensell, as was observed by Hous-say, Gusti, and Goñalons⁸⁰ This was carefully analyzed by Pasqualini (work being published) and shown to be due to insufficiency of the neuro-intermediate lobe affecting especially the renal function In toads polyuria occurs in 70 per cent of total hypophysectomies, in 33 per cent where the principal lobe is extirpated,* and in 20 per cent where there are diencephalic lesions (of the *infundibular lobe* or of the *pars basalis lamina terminalis*) In the first two groups it is immediate, progressive, intense and persistent, in those with diencephalic lesions the polyuria is transient

The renal origin of the polyuria, through a deficiency of neuro-intermediate secretion, is suggested by the following facts 1 The polyuria persists even when the animal is deprived of water until urine secretion ceases 2 From the moment the diuresis ceases the animal loses weight by evaporation until the final rate of evaporation equals that in controls 3 Water injected into the abdomen is eliminated more rapidly in the hypophysectomized animal 4 If the ureters are ligated, cutaneous absorption of water is equal both in hypophysectomized and control animals 5 The neuro-intermediate lobe and pitressin will stop the polyuria With very large doses oliguria or anuria may be produced 6 These results may be observed in animals deprived of water and with or without injection of water into the peritoneum 7 Large doses of neuro-intermediate lobe extract have another action completely apart from the renal This consists in the production of edema, with a great increase in weight, in both normal and nephrectomized animals^{5 171 262 410 411 412 etc} If the animal is placed in a hypertonic solution there is no such effect Pitressin is more active than pitocin Besides the renal action in these cases there is an increase in the permeabil-

*In this case probably owing to hypofunction of the remaining neuro intermediate lobe

ity of the skin to water¹²¹ For the sake of brevity I will omit further details
Thyiotropic anterior pituitary lobe extract causes polyuria in the dog by its thyroid stim-ulating action, but does not do so if the thyroid has been previously extirpated^{8 150} It is not modified by castration, section of the splanchnics, etc

MINERAL METABOLISM

Maenzer and Geischman have shown that the blood plasma of hypophysectomized dogs has a diminished amount of potassium^{88 112 113} In eighteen dogs the average was 163 mgm per 100 cc On the other hand the calcium is normal,^{34, 35 88 112 113} 116 mgm average in forty seven dogs, and so is the magnesium, 2.03 mgm in twenty dogs No significant alterations are found in chlorine, phosphorus, sodium and CO₂ (Table 1)

The decrease in the potassium of the plasma is not seen in thyroidectomized or pancreatectomized animals It occurs in some dogs with tubercular lesions (average 17.2 mgm in eight animals) probably due to a certain degree of pituitary hypofunction

Extirpation of the pituitary and pancreas in the same dogs causes the modifications found in both hypophysectomized (decrease in potassium) and pancreatectomized (decrease in calcium, chlorides and sodium) animals The alkali re-serve, however, is only a little lowered and acido-sis and ketonuria are very slight (attenuation of diabetes due to pituitary insufficiency)¹¹³

Alkaline anterior pituitary extract (in large doses intraperitoneally) causes an abnormal rise in the alkali reserve, and in phosphates, cal-cium, magnesium and potassium* The chlorides and sodium are lowered, the latter to a less marked degree (Table 1) These results are not due to hyperthyroidism since, except for the hypercalcemia, they are observed in thyroidec-

*Potassium returns to normal in the hypophysectomized ani-mals but is not modified in the controls It should also be remembered that diabetes develops under this treatment.

tonized animals, nor have they a nonspecific effect since they are not produced by extracts of kidney and muscle. The rise in calcium is not seen in thyroparathyroidectomized animals that is to say, when the parathyroids are missing.

The urinary elimination of phosphates is almost the same in hypophysectomized dogs as in normal animals when on a meat diet, but it is diminished more than in the normals during total fasting and the decrease is greater still when there is protein fasting.^{24, 25} There is a marked decrease of phosphatase in the serum of hypophysectomized dogs (Martinez, unpublished work).

IODINE METABOLISM

In more than twenty five papers, we have published the studies made in our Instituto on the relation between the thyroid and the pituitary. The anterior pituitary lobe controls the development and the maintenance of the anatomical structure and functional activity of the thyroid. Extirpation of the pituitary produces atrophy and hypofunction of the thyroid while an excess of the thyrotropic substance of the anterior pituitary causes morphologic and functional overactivity of the thyroid gland.

Hypophysectomy does not modify or only slightly raises the total iodine in the thyroid but the percentage content of iodine is manifestly raised.²⁷ (Table 2 and fig. 2) The iodine in

posterior lobe, thirteen craniotomized.* Lesions of the tuber and extirpation of the posterior lobe produce a lower initial rise in the blood iodine which is only transient. Extirpation of the thyroid causes an initial slight increase followed by a definite decrease to considerably below the normal level. We have attributed the initial rise in the blood iodine to the slight hyperthyroidism which frequently occurs during the first days after hypophysectomy. We did not obtain this initial increase in the blood

FIG. 1
Distribution curves of normal (dotted line) and hypophysectomized (solid line) dogs on the basis of the concentration of iodine in the thyroid.

FIG. 2
Chart showing the early rise and later fall of the blood iodine following hypophysectomy.
Abcissae—Days after hypophysectomy.
Ordinate— μ gm. iodine per 100 cc. blood.

iodine after hypophysectomy in two previously thyroidectomized dogs, which further supports our interpretation. This does not, however, explain satisfactorily why it should persist even when the thyroid is undergoing atrophy.

The average blood iodine in the second series was 13 μ gm. per 100 cc. blood. It did not show an increase when the tuber was in place.

Isidoro²⁸ has confirmed the existence of an initial hyperiodemia, but he found it to be transient and accompanied by hyperioduria. He believes that the hypophysis stores iodine sending it to the intermediate brain (rich in iodine according to Schittels and Eidel²⁹ and Sturms and Schneberger³⁰) which in its turn has a direct influence on the thyroid secretion and an indirect one by means of the thyrotrophic function of the anterior pituitary. Some of his arguments in favor of this are: that the hypophysis is peculiarly rich in iodine (as has been proved by H. G.); beside this is neither the first nor the only work to have determined the iodine content of the pituitary (see also the work of H. G. and Sturms and Schneberger).

TABLE 2
IODINE CONTENT OF THE THYROIDS OF DOGS UNDER
DIFFERENT EXPERIMENTAL CONDITIONS
(Mean Weight 9 Kgm.)

Operation and Number of Dogs	Total Iodine Mgm.	Iodine per Cent	Probable Error \pm	Variation % of Normal
32 Normals	0.95	63	3.7	0
17—Hypophysectomized during first month	—	85	6.5	—
14—Hypophysectomized 1 to 5 months later	1.12	100	7.7	+53

the blood rises considerably during the first few days after operation and later decreases over a period of two to four weeks, after forty five to sixty days it is always normal and remains so afterwards (Fig. 3). We have been able to add further results to those already published²⁷ and have so far studied a total of sixty one hypophysectomized dogs, thirty-seven controls eleven with lesions of the tuber six without the

Anterior pituitary lobe extract with thyrotropic action causes a marked decrease in the total iodine of the thyroid (alcohol insoluble and thyroxine iodine)^{90 91 185 230 231 249 250 318 391 etc} and prevents an increase after unilateral thyroidectomy⁹⁰ (Table 2) The blood iodine, (total and alcohol insoluble), rises considerably in normal,^{90 91 185 249 387 etc.} hypophysectomized or unilaterally thyroidectomized dogs with this treatment⁹¹ This hyperiodemia is due to the hyperthyroidism produced, since it is not obtained if dogs with total thyroidectomy are injected^{90 91} The last-mentioned animals usually present a decrease in blood iodine (due possibly to excessive elimination or greater fixation) *

The action of the anterior pituitary on the thyroid iodine and blood iodine is undeniable but it is impossible to tell whether the gland has a specific action, either direct or indirect, apart from its effect on the thyroid

*This suggests the possibility of another action of the extract on blood iodine opposed to the effect of the thyrotropic hormone

PROTEIN METABOLISM

The pituitary gland is an important regulator of the endogenous protein metabolism which it stimulates, whereas it has little influence on the exogenous protein metabolism It also takes part in the formation of sugar from protein

On a meat diet or the same mixed diet, hypophysectomized animals eliminate the same quantity of nitrogen per Kg per day, as the controls^{15-24 56 60 140} (Table 3) However, during the first six to seven hours after food their urinary excretion is less, with compensatory greater excretion during the remaining seventeen to eighteen hours^{15 21} If glycine is injected the curve showing its disappearance from the blood is more gradual than in the controls¹²⁰ There seems to be a slower fixation or catabolism of amino-acids

When fasting, hypophysectomized dogs^{15 21} and toads^{22 23} only eliminate two thirds of the quantity of nitrogen excreted by the controls On a fat and carbohydrate diet which is protein free (i.e, protein fasting) the decrease in

catabolism is even more marked in dogs¹⁵⁻¹⁷ and rats.⁴ With this diet only 0.18-0.20 Gm. of protein per Kg. per day is necessary to maintain the nitrogenous equilibrium in hypophysectomized animals whereas the controls require 0.30 Gm.

Since Folin's work, creatinine excretion is considered as the index of endogenous catabolism. This is slightly diminished in hypophysectomized dogs when on a meat diet^{18, 19} and very slightly altered in hypophysectomized rats.⁴ But during total fasting or protein fasting there is a decrease of thirty to forty per cent in both species. (Fig. 4 and table 4)

the expense of protein during diabetes is extremely diminished

The change in the endogenous protein metabolism cannot be due to the simple operative trauma or to a superficial lesion of the tuber, since it is not observed in craniotomized animals or in those without the posterior lobe or with injury of the tuber (galvanocauterization of 3.5 mm. in depth and width, from the pituitary stalk to behind the mammillary bodies).

Implantation of the principal pituitary lobe causes an increase in the nitrogen excretion in

FIG. 4

A. Average urinary excretion of A. Nitrogen and B. Creatinine of normal and hypophysectomized dogs (broken and solid lines respectively) during fasting.
Abscissae—Time of fasting in days.
Ordinates—A. Gm. N per Kg. body weight per diem.
B. Mgm. Creatinine per Kg. body weight per diem.

This lowered consumption of endogenous proteins is seen particularly and in a marked form in hypophysectomized animals suffering from pancreatic diabetes,⁴⁰⁻⁴² phlorhizin diabetes⁴³⁻⁴⁵ (table 5) or avitaminosis B and also after the injection of colibacillus.^{15, 21}

In all these cases, and also in simple or protein fasting, the loss of weight of the hypophysectomized animals is on an average less than of the controls. They are also able to survive longer if they are not killed by a concurrent attack of hypoglycemia.

The lowered protein catabolism cannot be explained by hypothyroidism because although thyroidectomized dogs have a decreased nitrogen excretion in simple or protein fasting when there is need of large protein destruction (e.g. in pancreatic or phlorhizin diabetes) this is as exaggerated as in the controls whereas the increase is very small in hypophysectomized animals. In the latter the formation of sugar at

fasting hypophysectomized toads.²² Injection of thyrotropic extract of the anterior pituitary lobe causes an increase in the nitrogen excretion of normal or hypophysectomized rats during protein fasting for the first few days (Braier and Morea, unpublished) and slightly increases the protein catabolism in dogs.⁴⁶ We have not yet verified the duration of this action or whether it occurs by way of the thyroid.

The metabolism of nucleoproteins has been studied by Braier^{22, 23} in hypophysectomized dogs and by Braier and Morea (unpublished data) in hypophysectomized rats.⁴ In both species the hypophysectomized animals eliminate less uric acid and purin bases but more allantoin, whether on ordinary diet or protein fasting. But the total sum of the three quantities is equal to that in the controls. (Table 6)

According to F. H. and Nowacki²⁴ in seven out of eight cases the increase in the endogenous utilization of the three substances (Schlitt's albumin and lipase) used a normal blood uric acid.

PLASMA PROTEINS AND NONPROTEIN NITROGEN	PHOSPHOCREATIN
In the plasma of twelve hypophysectomized dogs, Goldberg ³⁷ found an increase in the globulins (54 per cent) and in the viscosity (inconstant), but a decrease in the albumins (22 per cent) and in the A/G ratio (from 1.79 to 1.01). These modifications are identical with those seen in hypothyroidism.	When asthenia is well developed in the hypophysectomized toad (or in the toad after removal of only the glandular lobe) the phosphocreatin phosphorus in muscle diminishes in 33 per cent of the cases. The injection of glandular lobe extract or of mammalian anterior lobe extract brings it back to normal values. ^{104, 105}

tiapentoneally, produces not only a diabetic state, but also a marked increase in the total proteins, globulins, albumins and viscosity of the blood.³⁷ Immediately after injection of the extract there is a decrease in the nonprotein N which lasts several hours (Braier, confirming Teel and Watkins⁴¹⁹)

GLUTATHIONE
Helen Maveroff,¹¹⁴ in nine hypophysectomized dogs, found an average decrease of 10 per cent in the glutathione of the red blood cells (88 mgm per cent as compared with 98 mgm per cent in the controls). Injection of anterior lobe extract increases the glutathione in the red blood

cells of normal, hypophysectomized and thyroidectomized dogs.^{114*}

In the hypophysectomized toads (or after removal of the glandular lobe) when the asthenia is evident, the glutathione decreases in the muscles and more markedly in the liver, implantation of the glandular lobe prevents this decrease.¹⁰⁴⁻¹¹¹

UROBILINURIA

Hypophysectomized dogs eliminate 0.12 mgm. per day of urobilin in the urine (average of fifty determinations in six dogs). This is a normal amount (Royer unpublished data). Injec-

URINARY EXCRETION OF PHOSPHORUS IN FASTING DOGS (GERSCHMAN 1931)

(Recorded in Mgm. per Kgm. Body Weight per Diem)

	Meat Diet	Total Fast ing	Nitrogen Free Diet
Normals	46.5	17.7	15.1
Hypophysectomized	42.9	13.7	6.7

tion of 2 mgm per Kg tetrabromosulphalein in these animals is followed by a blood curve of normal aspect (Royer, unpublished data)

INDOXYLEMIA

This is normal in hypophysectomized and in thyroidectomized dogs.⁹³

PHENOLURIA

Hypophysectomized dogs eliminate normal amounts of urinary phenol when on a meat diet

Middleman¹¹⁶ observed a decrease in the glutathione of hypophysectomized dogs and that protein increased it.

but the excretion diminishes in fasting and more especially in protein fasting.^{11 25 101 105}

FAT METABOLISM

Adiposity is a symptom of pituitary insufficiency in some species, but not in others. It forms part of the adiposogenital syndrome in man, due to lesion of the hypophysis or of the tuberal region. On the other hand in pituitary cachexia (Simmonds syndrome) there is extreme emaciation. In hypophysectomized tadpoles the adipose organ persists.¹⁰⁴ Adiposity is frequently observed after hypophysectomy in puppies but occurs rarely in the adult dog. It is almost constantly seen, and in extremely accentuated form, in dogs surviving tubal lesions for a few months. (Solari¹¹² confirming Camus and Roussy.) In the rat, adiposity is absent or may appear for a short time in a slight degree. Sooner or later these animals lose weight and become cachectic. (Morea, confirming Smith 1927-30.)

In hypophysectomized dogs there are slight variations in the total fats, fatty acids, and cholesterol of the blood with a tendency toward a decrease.^{112 119 120*} Munoz has seen that repeated injections of a diabetogenic anterior pituitary extract produce a marked increase in the total lipids of the blood (which has a milky aspect), as also in the fatty acids, cholesterol and phospholipids.[†] This can be observed in dogs of both sexes, castrates, thyroidectomized and after section of both splanchnic nerves and extirpation of the lumbar sympathetic chain. Extracts of kidney and muscle prepared by the same technique do not have this activity. The liver in these animals also has a fatty aspect.

Dogs showing manifest adiposity owing to tubal lesions have a normal specific dynamic action. (Solari¹¹²)

Raab has proposed a theory which has been favorably received.^{140 70 256 262 292} He believes that pituitrin and lipotrin (which is found in both lobes of the pituitary and in the wall of the third ventricle) stimulate the tuber from whence impulses travel by the spinal cord and the splanchnic nerves to the liver, increasing the fats in this organ and in the blood, owing to an increased mobilization of storage fat and consumption by the liver. A disturbance of some part of this complicated mechanism would cause an increase in fat storage and consequently adiposity. Munoz¹²⁰ could not find any activity tending to decrease the blood lipids in posterior pituitary extracts, in spite of having injected as much as 100 mgm per kg of standard powder into dogs.

Karsh and Robinson¹¹⁷ find hyperlipemia.

[†]This increase in lipids is mentioned by Bauman and Marston.^{118 119} etc.

KETONEMIA AND KETONURIA

Hypophysectomy considerably diminishes ketonuria, to 60 per cent of the normal in dogs under basal conditions,¹²⁰ to 28 per cent of that of the control animals in pancreatic diabetes,^{123†} and to as low as 7 per cent of that of the control animals in phlorhizin diabetes during fasting^{125‡} (Table 7) Tuberal lesions also pro-

cant increase but the ketonuric activity of the extract was not altered by castration, extirpation of the adirenal medulla, lesion of the tuber or section of the splanchnic nerves with extirpation of the lumbar sympathetic chain^{1,2} (Table 7) In hypophysectomized phlorhizinized dogs the extract raises the excretion of ketones to the same level as in the controls

duce a small decrease in ketonuria in pancreatec-
tomized dogs

In hypophysectomized dogs on meat, sugar
or fat diets the ketone elimination in phlorhizin
diabetes is always smaller than in the corre-
sponding controls. Sugar intake diminishes the
elimination of ketones in the controls, but in
the hypophysectomized there is a slight rise.

Thyroidectomy, extirpation of the posterior lobe
and lesions of the tuber do not diminish
ketonuria as hypophysectomy does.¹²⁸

The ketonuric activity of the anterior pitui-
tary extract found in the rat by Burn and
Ling,^{139 159 172 173 209 226 236 237 238} has been stud-
ied in the dog by Rietti.¹²⁹ The total extract
produces ketonuria in normal animals and this
is more marked in partially pancreatectomized
and hypophyso-pancreatectomized dogs.^{68 69 70}
In thyroidectomized dogs there was no signifi-

The increase in ketonemia produced by the
anterior pituitary extract discovered by An-
selmino and Hoffmann¹³⁷ has been repeatedly
confirmed.<sup>137 138 139 162 219 238 246 258 259, 27* 310
335 339 340, 360 393 402 403 414 etc</sup>

The ketogenic extract has been called the
“fat metabolism hormone” by Anselmino and
Hoffmann and “Orophysin” by Magistis,
names that are not suitable and should not be
used because they presuppose something which
is not yet proved. According to Anselmino
and Hoffmann,^{137 (cf 246 393)} after a fatty meal
the blood contains this hormone in quantities
sufficient to produce effects when injected into
another rat. This substance is not identical with
the glycogen mobilizing one^{338 339} nor with the
thyrotropic hormone.^{139 159}

Urine has a ketogenic and ketonuric activ-
ity.^{236 237 238 239} Methods have been described
for the extraction and purification of this sub-
stance, both from the urine and the pitui-

†Long and Lukens¹²³ confirmed this in the cat
‡Black¹²⁵ confirmed this in the rat

tary^{127 128, 129 137 139} In thyroidectomized animals the ketogenic activity is less than in normals according to Fuuk,¹³⁶ or almost completely absent according to Eitel Löhr, and Loeser¹³⁹ and Rietti.¹⁴⁰ Other workers however find that it may be normal.¹³⁸ Prolonged administration of the ketogenic substance produces the appearance of an antihormone in the serum.^{141 152}

It is surprising with what assurance some investigators explain the numerous metabolic

effects of the pituitary or even all of its influence on the fat metabolism by the action of a single ketogenic hormone. Evidently the anterior lobe of the hypophysis participates in the regulation of the daily amount of urinary excretion of ketone bodies however it has not been definitely established whether its role consists in increasing their production or decreasing their consumption.

CARBOHYDRATE METABOLISM*

BY BERNARD A. HOUSSEY, M.D.

INTRODUCTION

DURING the last few years the important role which the pituitary plays in carbohydrate metabolism has been demonstrated. The essential physiological mechanism involves the anterior lobe, the posterior lobe having an accessory and much less important action. This is contrary to what has previously been supposed. The anterior pituitary lobe is probably, after the liver and pancreas, the most important regulator of carbohydrate metabolism. It would however be a grave mistake to imagine that the only metabolic function of the anterior pituitary is its action on carbohydrates. It holds a central position in the general metabolic regulation (water, iodine, protein, carbohydrate, fat, ketogenesis, etc.), as well as having essential and important actions on the endocrine system.

The alterations in the carbohydrate metabolism are especially marked in the toad which is therefore the animal par excellence for its study. The changes appear or become accentuated about three weeks after hypophysectomy or extirpation of the principal lobe alone. At the same time symptoms of progressive neuromuscular asthenia develop together with decrease in blood sugar and glycogen which causes death in four to eight weeks, survival for months being exceptional. Implantation of the principal lobe corrects these changes and prevents death. Similar symptoms are observed in hypophysectomized rats when they become cachectic. In dogs the compensation apparently is better for they can survive for months or years in an apparently good state. However, they may present mortal cachexias or hypoglycemia. Despite their good appearance their metabolism is modified, as may be demonstrated by subjecting them to agents that induce hypoglycemia, or by producing diabetes, either by extirpation of the pancreas or by the administration of phlorhizin, these modifications affect particularly the metabolism of fasting animals.

Lesions of the tuber cinereum or of the hy-

pothalamus have a varying effect on the pituitary functions, according to the localization and extent of the lesion. In certain cases they cause marked inhibition of the anterior pituitary function which may be corrected by administration of the anterior pituitary lobe.

THE BLOOD SUGAR IN HYPOPHYSECTOMIZED ANIMALS

Normal Blood Sugar. Many investigators have found subnormal blood sugar in hypophysectomized animals, dogs^{126 279 280 793 91 322} rabbits,^{181 182} and in the pituitary cachexia of human beings. In reality if the animals are properly cared for and are kept on an adequate diet, it has been found that the blood sugar remains within normal limits* in dogs^{126 1 47 50 35 36 36 47} rabbits,^{181 279 280} cats,²²⁷ rats,²⁸ and amphibians.^{29 73 92, 94 101 427}

However one of the most salient characteristics of pituitary insufficiency is the tendency to hypoglycemia during fasting, which becomes manifest after a few hours.

Hypoglycemia. Hypophysectomized animals readily become hypoglycemic and may present grave symptoms, frequently terminating in death. Treatment with sugar produces symptomatic improvement but must be initiated early and repeated frequently. Good results from injection of adrenalin or postpituitary extracts are much rarer.

The hypoglycemia may be classified according to their cause as postoperative spontaneous, due to fasting cachexia, insulin phlorhizin secondary etc. After operation^{28 68 24 421} or during the evolution of pituitary cachexia^{126 279 51 37 2, 6 7 351 265 279 280 481 43} hypoglycemia and hypoglycemic crises frequently occur. Spontaneous¹²⁷ hypoglycemia observed first by Wilder⁴²² in man and by Houssey and Biasotti⁵⁸⁻⁶⁰ in dogs has since been seen in dogs,^{126-59 157 66 90} rabbits,^{181 421} guinea

In 6 hypophysectomized dogs we found 0.037 per cent in the morning and 0.1 per cent 3 hours after a meal (normal in 0.2 controls). The figures were 0.109 per cent and 0.128 per cent respectively.

pigs²²² and rats. The surprising feature is that it may develop in hypophysectomized dogs which are also pancreatectomized^{56 60}. We have never seen spontaneous hypoglycemia in dogs with extensive lesions of the tuber (retro-pituitary), but D'Amour and Keller²⁰⁰ have observed it with lesions in other parts of the brain.

Fasting is the essential factor in the rapid, progressive decrease of the blood sugar, which, if not treated, may produce serious or even fatal accidents. This has been proved principally by Bjaer^{14 21} and has been confirmed in the dog,^{15 21 58 187 200 325 334} rabbit,^{191 431} and monkey¹⁸⁷. While the blood sugar level is low there is little glycogen in the liver in dogs (Houssay, unpublished) and rabbits¹⁹¹.

Phlorizin produces a rapid hypoglycemia in the fasting dog^{56 62} and in the toad,²⁸ accompanied by convulsions and death. These accidents usually appear in the dog on the third day, when the blood sugar is below 70 mgm per cent. Under these conditions we lost fifteen out of seventeen hypophysectomized dogs. Feeding meat and sugar prevents the hypoglycemia and the consequent accidents, but feeding fat is not efficacious¹³. Treatment with a diabetogenic anterior pituitary extract, before and during fasting, prevents the occurrence of hypoglycemia and death.^{48 49 50 66}

Secondary hypoglycemias are observed after epinephrin,^{14-21 325} and glucose³²⁵ hyperglycemias, and may be serious if they occur after fasting.

Sensitivity to Insulin. Another remarkable peculiarity of pituitary insufficiency is the extreme sensitivity to the toxic and blood sugar reducing actions of insulin, which even in small doses produces convulsions, coma and frequently death. In hypophysectomized animals the fall in blood sugar is more rapid, more marked and lasts longer than in the normal, and recuperation is difficult and slow if it takes place at all. Early, intense and repeated treatment with cane sugar, glucose or posterior pituitary extract is necessary, and is frequently efficacious in the dog. This extreme sensitivity to insulin, which we found with Magenta in 1924 has been proved in dogs,^{85 86 87 148 149 199 216 241 242 279 293 325 332 333 etc.} cats,³³⁷ toads,^{93 96} monkeys,²⁶⁰ rabbits,^{190 191 235 297 298 379 380 381} and man^{141 102 257 327 335 349 366 etc.} but apparently is not present in birds.⁶⁸ It is also seen in hypophysectomized dogs from which the pancreas as well has been removed.*

The protective action of anterior lobe extract is very potent and is incomparably superior to that of the posterior lobe extract. It is able to correct the sensitivity to insulin and even to produce a supernormal resistance. This occurs in both normal and hypophysectomized toads,⁹⁵

dogs^{29 332} and rabbits¹⁹⁰. Injections of anterior pituitary extract for one to two days are needed to reinforce the resistance²⁹ since such injections are unable to save animals already in convulsions or coma.⁸⁷

A number of observations have been made on the relation of the thyroid to the hypersensitivity to insulin. The protective action of anterior pituitary extract is also evident in hypophysectomized-thyroidectomized animals (di Benedetto, Houssay). The hypersensitivity of hypophysectomized dogs is much greater than that of thyroidectomized dogs. Thyroidectomized rabbits¹⁹⁰ and thyroidectomized dogs (Houssay) become far more sensitive to insulin when they are later hypophysectomized. Thus it is clear that the decrease in resistance to insulin is not due to hypothyroidism in the hypophysectomized animals but to the lack of the anterior pituitary lobe.

It has been thought that the hypersensitivity to insulin is due to hypofunction of the adrenals,¹⁵² because extirpation of the latter produces a similar hypersensitivity, as shown by Lewis and Magenta in our Institute. Furthermore, in pituitary insufficiency there is often an atrophy of the adrenal cortex. In opposition to this view we cite the following observations. Anterior pituitary extract has a diabetogenic action on hypophysectomized-pancreatectomized toads from which the adrenals also have been removed, and on dogs after extirpation of the adrenal medulla or after complete adrenalectomy.^{84 101} It also increases the resistance of the latter to insulin. According to Barnes, Dix and Rogoff¹⁴⁸ hypophysectomized dogs require more adrenalin to prevent convulsions than dogs with denervated adrenals. These authors maintain that hypophysectomized animals do not liberate adrenalin during the hypoglycemia due to insulin. Cope and Maiks¹⁹⁰ showed, however, that there was a hypersecretion of adrenalin, and they advanced the idea that the glycogenolytic action of adrenalin is less marked in the absence of the anterior pituitary lobe.

Our opinion is that pituitary insufficiency causes the suppression of a hormone which is necessary for the metabolism of carbohydrates, and that it is the lack of this hormone which causes hypersensitivity to insulin. Adrenal insufficiency may be an additional cause.

Hypoglycemic action of the blood. Cowley¹⁹² stated that the blood of hypophysectomized animals produces hypoglycemia in rabbits but this was found in only one case out of three by Daggs and Eaton¹⁹⁹ and could not be confirmed by di Benedetto³⁰ using the blood of sixteen hypophysectomized dogs.

Kepinov and Guillaumie²⁰¹ using a pancreatic anastomosis have found that the pancreatic blood of hypophysectomized dogs is more

*Unpublished data. See also 187 and 367.

HYPERGLYCEMIAS IN HYPOPHYSECTOMIZED
ANIMALS

Adrenalin^{191 235 297 381} or pilocarpin²⁹⁸ hyperglycemia is less marked in hypophysectomized rabbits than in normals and grave secondary hypoglycemias usually follow. Similarly, hypophysectomized toads have a lower hyperglycemia after adrenalin and morphine injections⁷⁵. Parathormone does not cause a rise in blood sugar in hypophysectomized pigeons³⁷⁰. The hyperglycemia of avitaminosis¹⁹ fails to occur in hypophysectomized dogs while that caused by ether is less intense than in normal controls³¹. The hyperglycemias due to glycerol,¹²⁶ thyroxin^{279 229 330} and pituitrin^{279 293} are somewhat greater. The morphine hyperglycemia is similar in hypophysectomized and in normal dogs³¹.

Adrenalin subcutaneously does not usually produce glycosuria in hypophysectomized dogs as it does in the controls^{39 140}. The blood sugar rise has been found both greater^{293 325 326 327 332 333} and less^{16 279} after hypophysectomy. Briani¹ observed that after eighteen hours' fasting the rise is slightly less in the hypophysectomized dogs than in the controls. After four days of fasting there is still less hyperglycemia and a marked secondary fall in blood sugar (six out of ten of the dogs dying in hypoglycemia).

PANCREATIC DIABETES IN HYPOPHYSECTOMIZED
ANIMALS

Hypophysectomy brings about a marked alleviation of the symptoms of pancreatic diabetes resulting in a less intense and slower development of that disease. The hypophysectomy is equally efficient if it is performed before or after the pancreatectomy. This alleviation of pancreatic diabetes, which we proved with Bisotti and described in 1929-30,^{15 58*} has been

*Görsch, Cushing and Jacobson⁴⁵ had previously observed that subtotal hypophysectomy may increase glucose tolerance in dogs with a subtotal pancreatectomy. In experiments which were repeated by Cushing¹⁰ and Davidoff and Cushing²⁰²

amply confirmed in dogs,^{58 59 113 128 129 147 149 159 186 187 286 289 290 299 329 367 409} cats,^{204 205 327 373} amphibians,^{6 22 23 25 56 65 84 *} reptiles (*Ophis meieri* Wagler^{63 64 65}), fishes (*Mustelus canis*³⁵⁹)

Hypophysectomized toads and toads in which the principal lobe alone has been extirpated do not have glycosuria and there is little or no hyperglycemia, nor is the urinary nitrogen excretion raised, on removal of the pancreas. On the other hand, diabetes appears with normal, or even supernormal, intensity if the principal lobe is implanted (the neuro-intermediate lobe is less active) (Table 8).

We have studied sixty-five hypophysectomized pancreatectomized animals. On the basis of this material it may be stated that the usual syndrome of pancreatic diabetes in mammals undergoes numerous changes due to the hypophysectomy. As compared with control cases of pancreatic diabetes in otherwise normal animals, the hypophysectomized-pancreatectomized animals show the following characteristics. Survival is prolonged and may reach six,⁵⁸ or even nine months^{147 187}. The wounds heal and there are fewer infections. The loss of weight occurs more slowly. Glycosuria diminishes and some times is not present, and fasting causes a more marked decrease. Polyuria is scarce or absent, depending on the degree of glycosuria. The blood sugar in general is lower, oscillating between 0.1 and 0.25 per cent (Table 9). Sometimes there is no hyperglycemia and it is even possible for hypoglycemic crises which improve on administration of sugar to occur. Together with this there is hypersensitivity to insulin^{149 187}. The ketones in the blood and urine decrease markedly, but the alkaline reserve falls slightly or not at all, although the calcium in the blood is lowered†. There is a small increase

*In the species *Bufo arenarum*, *B. marinus*, *B. paracnemis*, *B. d. orbigny*, *Ceratophrys ornata*, *Leptodactylus ocellatus*.
†With lesions of the parathyroids but it is also observed when pancreatectomy alone is performed.¹¹³

in the catabolism of proteins (slight and slow loss of weight, slightly increased nitrogen elimination during fasting.) The dextrose nitrogen ratio is low. The lipids and cholesterol in the blood rise less than in the controls.^{11, 12} The hepatic and muscular glycogen may be found in normal quantities,^{43, 64, 65, 147} although following tetanization the restitution of muscle glycogen may not occur until after an hour.⁷ If sugar is administered, the animals can partially or even sometimes totally utilize it.^{12, 60} The respiratory quotient rises occasionally as much as in normal animals^{12, 64, 149} (Fig. 6.) The hyperglycemic curve falls more rapidly than in animals with pancreatic diabetes, although more slowly than in normals. Repeated administration of sugar aggravates the diabetic state.

This proves clearly that even without the internal secretion of the pancreas the organism can utilize sugar. In pancreatic diabetes it seems that the secretion of the anterior pituitary increases the production of glucose and diminishes its consumption so that the organism becomes overcharged with sugar.

The work of Kepinov¹⁴⁸ is in favor of this hypothesis of ours. This investigator found that transfusion of the blood of pancreatectomized dogs into normals caused a secondary net rise of blood sugar (independently of the sugar injected) which did not occur if the blood of

pancreatectomized-hypophysectomized animals was used

According to Boller, Uiberrak and Falta¹⁶¹ if the blood of healthy individuals injected with insulin is transfused into normals it causes a lowering of the blood sugar of the recipient. If, however, the donor is an insulin resistant subject injected with insulin, hypoglycemia is not produced in the recipient. The blood of insulin resistant individuals seems to contain one or more antagonistic bodies.

Folliculin X-Rays — It has been possible to modify pancreatic diabetes by inhibition of the pituitary in other ways. With treatment by folliculin the pancreatic diabetes of dogs^{149 151 352 353} and monkeys^{352 353} has been prevented or improved and its development retarded. Human cases of diabetes have also been improved in this way.^{348*}

On the other hand, unpublished observations of Biasotti indicate that irradiation of the pituitary, before or after pancreatectomy, gives no results (cf. 398). It is, however, uncertain whether the pituitary is affected by this treatment. This method has been tried in human diabetes.^{214 234 373} etc.

PANCREATIC DIABETES OF THYROIDECTOMIZED AND ADRENALECTOMIZED ANIMALS

Thyroidectomy does not alleviate pancreatic diabetes in dogs.⁴³⁵ If in a pancreatectomized dog all adrenal tissue is extirpated and the administration of insulin is suspended, there is a marked rise in blood sugar which may remain at a high level or may decline.^{145 247 261 311 316} Dogs with no adrenal medulla have an intense pancreatic diabetes.^{276 311 415 423} Thus it is clear that the adrenal is not indispensable for the rise in blood sugar to the diabetic level nor is the adrenin from the adrenal necessary for its maintenance.†

With unilateral adrenalectomy we did not find any modification of the pancreatic diabetes, although Barnes, Scott, Ferill and Rogoff¹⁵² observed this. Long and Lukens^{322 323} found that adrenalectomized-pancreatectomized cats maintained with cortin, presented an attenuated diabetes with little or no hyperglycemia, glycosuria or ketonuria. Both groups of investigators think that possibly hypophysectomy causes alleviation of the diabetes because it provokes an adrenal hypofunction.

DIABETES AND HYPOTHALAMIC LESIONS

In a certain number of dogs and cats^{39 53 140 155 179 180 183 232 243 255 264} etc. a transient glycosuria is noted after hypophysectomy. This is not due to the glandular deficiency because it

is observed after mere manipulation of the hypophysis without extirpation.^{179 180 245} etc. and after lesions of the tuber cinereum.^{39 47 140 144 180 201 204 207 313 314 346 378} etc. It has also been noted that hypothalamic excitation may cause a rise in blood sugar.^{270 280 341 350}

The glycosuric action of excitation of the superior cervical sympathetic ganglion has been attributed to a pituitary hyperfunction, but this has not been confirmed.^{188 288 365} The fact that it ceases on section of the splanchnics and on bilateral lesion of the hypothalamus²⁰⁴ suggests the possibility that there is a central reflex which acts through the liver or the adrenal.^{277 282}

Lesions of the nuclei in the wall of the third ventricle sometimes produce glycosuria in the rabbit.^{177 305} Dewulf,^{210 211} however, could not confirm this by making lesions in these nuclei, although when there were other mesencephalo-diencephalic lesions, excluding the tuber, glycosuria did occur. It is as well to mention that both investigators observed some cases of spontaneous glycosuria. We ourselves have never observed a permanent hyperglycemia or glycosuria in dogs with either circumscribed or extensive lesions of the diencephalon. On the other hand, certain hypothalamic lesions may cause hypoglycemic crises.²⁰⁰ Although lesions of the diencephalon and of other central zones have been observed in some cases of diabetes.^{215 307 308 309 312 314 345 347 355 399 425} etc. they are usually absent.^{210 305}

Certain lesions of the tuber may inhibit the pituitary diabetogenic secretion since Houssay and Biasotti^{56 60} found that following such lesions there was a marked decrease in the pancreatic diabetes of toads,* but that implantation of the glandular lobe resulted in its reappearance. The pituitary of these toads contained diabetogenic substances, but apparently could not secrete it. Our dogs with tuberal lesions extending from the pituitary stalk to behind the mammillary bodies, developed a pancreatic diabetes as severe as that of the controls.^{58†} However, after more extensive hypothalamic lesions (caudo-dorso-lateral to the mammillary bodies, in the region of the ventro-medial nucleus of the hypothalamus) pancreatectomy did not produce a high blood sugar and life was prolonged in both dogs and monkeys.^{204 205} Anterior pituitary extract aggravates this attenuated diabetes. Davis's opinion, quoted from a letter, coincides with ours and is "that we have simply produced a functionless pituitary gland by interference with its blood and nerve supply with the lesion in the hypothalamus, which must be very accurately placed."

*In the fish *Mustelus canis* after the tuberal lesion was produced there was a slight increase in the pancreatic hyperglycemia.

†Biasotti (unpublished) observed a remarkable case in a child.

‡The relationship of the adrenals to diabetes is considered in detail with a very complete bibliography by my pupil Leloir.³¹¹

†The glycaemic curves following injection of glucose in dogs with tuberal lesions are similar to those seen in normal controls.^{10 11 12}

PHLORHIZIN DIABETES OF HYPOPHYSECTOMIZED ANIMALS

Hypophysectomy causes a decrease in the intensity of phlorhizin diabetes* in fasting dogs^{15 16 50 55 56} (table 10) and toads,⁵ but the blood sugar falls rapidly, death occurring in from two to seven days (fifteen out of seventeen dogs). The glycosuria ketouria^{1 1 1 1 9} urin

the direct stimulation of the pancreas found by La Barre, although the latter used adrenalectomized dogs while those of Foglia had intact adrenals.

Posterior lobe extract, even in repeated large doses does not produce diabetes in normal dogs^{46 50 427} or in dogs with incomplete removal of the pancreas^{62 70} but causes a slight rise in

ary nitrogen, dextrose nitrogen ratio and loss in weight, are all diminished (Table 10). On a meat or sugar diet, hypoglycemia and death do not occur, but on a fat diet they do. In all cases less sugar is excreted by the hypophysectomized animals than by the controls. Tubercular lesions or previous thyroidectomy do not affect the phlorhizin glycosuria.

ACTION OF PITUITARY EXTRACTS ON THE BLOOD SUGAR

Extract of the posterior pituitary lobe raises the amount of sugar in the blood. Extracts with three different actions can be obtained from the anterior lobe, (a) with hypoglycemic action (b) with slight quick transitory hyperglycemic action due to intervention of the adrenals and (c) with diabetogenic action.

Hyperglycemic action of posterior lobe extracts.—Since Borchardt⁴⁶ found that posterior lobe extracts produced glycosuria this phenomenon, together with the hypoglycemia has been the object of numerous studies. We have shown^{74 77} that the hyperglycemic action is slight and increases with the dose, and that the vasopressor substance has the more intense action. It does not develop if the liver or adrenals are extirpated but if the pancreas alone has been removed it is normal and there is very little increase after section of the vagi. The action is on the liver with participation of the normal adrenal secretion. It has not been possible to demonstrate an increase in the secretion of adrenalin. Foglia¹ could not confirm

the blood sugar of hypophysectomized animals with no pancreas. The neuro-intermediate lobe in the toad (corresponding to the posterior lobe of mammals) has similar metabolic actions to those of the principal lobe, although less intense. It counteracts the toxic and hypoglycemic actions of insulin,⁵⁰ increases the diabetes of hypophysectomized pancreatectomized toads,⁴⁷ counteracts the asthenia and lengthens the life of hypophysectomized toads¹ and causes an increase in their diminished glycogen content.^{48 49 50}

Hyperglycemic action of the anterior lobe.—Certain anterior pituitary lobe extracts produce hypoglycemia.^{133 72 339 340 495 496} etc. According to Anselmino and his collaborators they have a pancreatotropic action since they cause hypertrophy of the islets of Langerhans in the rat and do not produce hypoglycemia in pancreatectomized dogs. The increase in the secretion of insulin was proved by Zanz and La Barre,⁴²⁰ using a pancreaticojugular anastomosis. The pancreatotropic hormone is active in thyroidectomized animals; it decreases alimentary and adrenalinic hyperglycemia and lowers the glycogen content of the muscles. Its preparation and properties have been studied in detail by Anselmino and his collaborators.

The rapid and transient hyperglycemic action of anterior lobe extracts and of urine.—The commercial extract (of unknown preparation)

The fact that it has an antihypoglycemic action in the dog has been mentioned also (see under Anselmino's findings in hypophysectomized dogs, etc.).

The effect in this respect is considerably less than that of the anterior lobe and is destroyed by boiling for 10 min. at 100°C.

Anselmino very kindly sent me his histological preparations.

*Author's personal observation.

¹This work has been summarized by House and Foglia in the following paper.

used by Lucke and his collaborators caused an immediate rise in blood sugar of not more than 30 to 50 mgm per cent which lasted for a few hours. This action is produced through the sympathico-adrenal path and is absent in adrenalectomized animals and in those with section of the splanchnics or under the influence of ergotamine or somnifen. It has a rapid action if injected into the cerebrospinal fluid†. This immediate action has also been found in other extracts^{274 400}.

Extracts of normal urine or pregnancy urine contain hyperglycemic substances^{63 64 65 103 206 217 258 etc.} which can also be found in the ketogenic extracts prepared from them^{258 402 403}. These do not invariably alter the blood sugar nor do the following purified prolactin^{206 213 327 408 etc.} the galactotrophic substances,³⁵⁴ the thyrotrophic substances,^{327 330} nor various other pituitary extracts²⁷⁸. The action of the urine is due to the uric or hippuric acid according to Davis, Hinsey and Maizee²⁰⁶.

Glycogenolytic action—The hepatic glycogen decreases after injection of various extracts of anterior pituitary lobe^{139 274 284 327 433 etc.} The ketogenic^{402 403 414 etc.} and especially the thyrotrophic^{218 219 319 389} extracts have this effect.

According to Anselmino and Hoffmann¹³⁹ the anterior pituitary contains a glycogenolytic substance (on which they have bestowed the rather unfortunate name of Kohlehydratstoffwechselhormon) which is secreted into the blood. After a carbohydrate meal the blood, if removed and injected into a rat, has the power of diminishing the hepatic glycogen. In fasting the blood does not have this power except in diabetics. The blood of hypophysectomized dogs does not acquire the glycogenolytic capacity after carbohydrate intake. Hoffmann and Anselmino²⁷³ describe the properties of the hormone and its separation from the ketogenic substances.

Glycogenetic action—According to Magistius^{338 339 340} certain extracts of anterior pituitary lobe allow glycogen to be formed in the livers of rats in hyperthyroidism when sugar has been administered.

DIABETOGENIC ACTION OF ANTERIOR PITUITARY LOBE EXTRACT

Amphibians—In hypophysectomized-pancreatectomized amphibians, particularly the toad, glandular lobe extract of amphibians birds, fishes and mammals^{63 64 65} produces diabetogenic effects which are more intense than those produced by the intermedio-neural or posterior lobe extract. Anterior lobe raises the blood sugar of normal toads only slightly but produces

a considerable increase in the diabetes of hypophysectomized-pancreatectomized animals, with hyperglycemia, glycosuria^{56 60 61 62 64} (table 8) and an increase in urinary nitrogen²². This diabetogenic action does not occur if the liver is absent²⁵ although the muscular glycogen falls less than in the untreated hepatectomized controls. The diabetogenic action is observed in hypophysectomized-pancreatectomized animals even if the thyroids or testes, digestive tract kidney or adrenals, diencephalon and anterior cerebrum are absent^{56 60}.

In hypophysectomized toads, extracts of this lobe cause an improvement of the asthenia and a lengthening of the survival time,^{48 49 50} there is a rise of glycogen⁷⁸ and of lactic acid formation during tetanic stimulation of the muscles¹⁰⁶. It also causes an increase in the glycosuria following phlorhizin²⁸ and in the hyperglycemias following adrenalin and morphine injection⁷⁵.

Normal mammals—The hyperglycemic and glycosuric actions of anterior lobe extract have been described by Johns, O'Mulvenny, Potts and Laughton^{284*}. The diabetogenic action has been observed and studied minutely by Evans,† Houssay,^{9-12 29 48 49 50, 63 66 69 70 71 74} Baumann and Maime,¹⁵⁴ Baines and Regan,¹⁴⁹ and E I Evans²²¹. It is the only glandular extract known at present which will produce a definite diabetic state,‡ since extracts of liver, muscle, thyroid, spleen, kidney, testicle posterior pituitary lobe, and adrenalin all either have no action on the blood sugar or increase it only slightly.

In the dog the blood sugar gradually rises from the second or third day of injection until it reaches levels of 0.18 to 0.30 per cent (on carbohydrate diet the rise occurs more rapidly and is more intense) (Fig 7). After two days and before hyperglycemia develops there is considerable increase in the resistance to the toxic action of insulin (both in normal and hypophysectomized animals) even if the thyroids or adrenal medulla are removed^{29 190 327}.

The hyperglycemias due to adrenalin and morphine are also increased^{76 77}.

Besides the hyperglycemia there is glycosuria, ketonuria,^{129§} increase in plasma proteins³¹, increase in hematic glutathione,¹¹⁴ hyperlipemia and hypercholesterolemia,^{120 154 221} acidosis,²²¹ etc. During the hyperglycemia there is diminished glucose tolerance (fig 8) since the hyperglycemia curve falls gently and approximates the diabetic one^{9 10 11 12 149 221}. The respiratory quotient does not rise and part of the injected

*They do not give their method of preparation of the extract, but they say it is protein free (which seems impossible to us) and their glycemiae are not over 0.150 per cent.

†Evans, Meyer, Simpson, Relchert^{222 224} produced diabetes which persisted for a few weeks after the treatment had been discontinued.

‡The extract should be prepared from fresh frozen anterior lobes and kept at a low temperature.

§It is also seen after extirpation of the gonads or section of the splanchnics etc. but not after thyroidectomy.

†We found the action of this extract to be very weak even repeated high doses did not increase the glycemia more than 30 mg per cent transiently and showed no diabetogenic action.

sugar is eliminated.^{9 10 11 12} It is worthy of note that during the intense hyperglycemia there is an increase in glycogen.¹⁴ (Table 11)

This action is observed in various species and can be obtained in castrated or thyroidectomized dogs.

10 Hypophysectomized and pancreatized dogs	3.33	3.04	58	350

(1) The chloralose anesthesia has an unfavorable influence on the hypophysectomized dogs. With out anesthesia—77 Gm. % in the liver and 510 mgm. % in the muscle (averages of 7 hypophysectomized dogs) 3.48% in the liver and 659 mgm. % in the muscle (average of 6 normals). (Houssey Blasotti unpublished data.)

tomized dogs and in those with no adrenal medulla, with lesions of the tuber, or with section of the splanchnics and extirpation of the lumbar sympathetics.¹¹ If dogs deprived of one adrenal are injected with anterior lobe ex-

tract and when in hyperglycemia the second adrenal is removed but with the injections still continued the blood sugar remains high or falls gently during two or more days whereas there is a rapid fall if the injection of extract is suspended when the second adrenalectomy is performed. (Fig. 9.) For this reason and also be-

cause of increasing activity: cats, dog, pigeons, guinea pigs, rabbits, rats, mice. It was not obtained in toads and snakes.

cause the diabetogenic action can be obtained in hypophysectomized-pancreatectomized and adrenalectomized toads, it is evident that this pituitary extract has its own action which is independent of the adrenals.²

The diabetes produced by the anterior pituitary lobe extract has five marked characteristics (1) it generally does not occur until the second or third day, (2) it does not occur or is hardly evident during fasting, (3) if administration of the extract is suspended the blood sugar falls rapidly and reaches a normal level in one to three days, (4) it is accompanied by a rise in glycogen (this is the only diabetes in

FIG 9

Blood sugar in dogs. In all cases one adrenal was removed and anterior lobe extract injected until the blood sugar rose above 1.6 Gm per 1000 cc. The remaining adrenal was then removed.

The injections of anterior lobe extract were continued in the cases shown in graph A but were stopped in those shown in graph B.

Abscissae—Time in hours after complete adrenalectomy.
Ordinates—Blood sugar in Gm per 1000 cc. blood.

which this occurs), (5) the diabetes occurs even if the thyroids and suprarenals are absent.

If the injections are continued the blood sugar may fall to normal levels,²²¹⁻⁴⁰⁰ which gives rise to the theory that there may be an antihormone¹⁸⁶ however, it must be remembered that diabetes has still been observed after several months of uninterrupted treatment.²²³⁻²²⁴

Action in the pancreatic diabetes of hypophysectomized animals—When there is subtotal pancreatectomy (with or without glycosuria) the diabetogenic action is particularly intense. If there is total pancreatectomy all the symptoms of diabetes are intensified, especially the ketosis, and death occurs in one to three days.

In hypophysectomized-pancreatectomized mammals the anterior pituitary lobe extract causes an increase in the diabetes. The hyperglycemia, ketonuria, glycosuria, etc., reach abnormally high figures. These effects occur in

the same manner whether the thyroid or gonads are extirpated or not.

Action in phlorhizin diabetes—In the toad⁵⁵ and particularly in the dog⁶⁵⁻⁶⁶ anterior pituitary extract causes an aggravation of phlorhizin diabetes in hypophysectomized animals, it doubles the glycosuria, causes an immense increase in the ketonuria, accelerates the fall in weight, and increases the diuresis, but prevents the hypoglycemia and rapid death.

NAME, PROPERTIES AND ACTION OF THE SUBSTANCE WHICH IS ACTIVE ON CARBOHYDRATE METABOLISM

Of the substances present in the anterior pituitary secretion, the blood sugar lowering agent has been demonstrated pharmacologically but not physiologically. We do not yet know the importance of the glycogenolytic agent (the Kohlehydratstoffwechselhormon of Anselmino and Hoffmann). It can, however, be taken as proved that there is an anterior pituitary secretion which maintains the normal blood sugar, prevents the occurrence of hypoglycemia and raises the blood sugar in diabetes.

One may speak of the diabetogenic action of the extracts but it is not advisable to say there is a definite diabetogenic hormone, since its normal physiological action cannot be to produce diabetes. It seems that its action is to stimulate and facilitate the production of sugar and perhaps regulate its utilization, in large doses it produces hyperglycemia and diminishes sugar consumption. It would be more satisfactory to call it the glucose regulating (or glucido-regulating) hormone of the anterior pituitary.

Although in general it has antagonistic actions to those of insulin, it should not be called a contra-insular hormone (Lucke) because (1) it acts in hypophysectomized-pancreatectomized animals and its rôle is not exclusively anti-insulinic, (2) many other hormones (viz., adrenalin, posterior pituitary, etc.) are anti-insulinic. It has a direct action, not through its influence on the thyroids or adrenals, although it is clear that its effectiveness, like that of other agents, is less or may even fail in profound adrenalectomy.

The chemical properties of the glucose regulating hormone are not completely known although we⁵⁶⁻⁶¹ have studied them in the toad and the ox.⁷¹⁻³²⁵⁻³²⁶⁻³²⁷ It is soluble in water, partially so in alcohol at 50-60°, insoluble in acetone, absolute alcohol, ether, methyl alcohol, chloroform, benzene, partially precipitated by 95 per cent alcohol, acetone, and 30 per cent Na₂SO₄ (anhydrous). It is destroyed rapidly by heating above 55° to 80° C. It is absorbed by charcoal or kaolin and in great part by the filters. It is not ultrafiltrable or dialyzable. It is distinct from the gonadotropic, thyrotropic and mammatropic hormones but cannot be separated from the growth hormone.

*In contradistinction to what has been maintained by Lucke²²³⁻²²⁴⁻²²⁷ perhaps because his extracts had little activity or were of another kind.

PITUITARY AND LACTIC ACID

Marenzi's work¹⁰⁶⁻¹¹¹ has shown that there is an increase in the lactic acid of the blood due to the action of posterior pituitary lobe extract and during the diabetic action of anterior pituitary lobe. The lactic acid is normal in the blood of hypophysectomized animals and is also normal in the muscles of resting hypophysectomized toads (or of those with extirpation of the posterior lobe). After several weeks however, tetanization causes a smaller increase of lactic acid as compared with the normal; probably because the initial content of glycogen is diminished.

CARBOHYDRATE METABOLISM IN DISEASES OF THE HUMAN PITUITARY

It has already been mentioned that in serious pituitary insufficiency there is hypoglycemia with hypoglycemic crises and hyperactivity to insulin. Hyperglycemia due to glucose or adrenalin may be less²⁶¹ or greater than in normals²⁶²⁻²⁶⁷ but is frequently followed by profound secondary hypoglycemia.

Glycosuria is very frequent in cases of Cushing's syndrome (it was found in nine out of twenty-three cases in which basophilic adenoma of the pituitary was histologically confirmed). There may be hyperglycemia with prolonged glycaemic curves²⁶⁷. The insulinic hypoglycemia curve is normal²⁶⁷ or lower²⁶⁸ but without hypoglycemic symptoms.

Glycosuria and hyperglycemia are frequent in acromegaly, there is a diminished fall in blood sugar due to insulin, and the alimentary glycaemic curves are prolonged,^{25 217 261 3 313 314 361} etc.

(3) Anterior pituitary extract can produce diabetes in normal mammals.

(4) When the pituitary is absent there is a tendency to hypoglycemia hypersensitivity to insulin and other hypoglycemic agents, etc.

In acromegaly glycosuria is frequent (table 12) and occasionally it is even possible for a diabetic state to develop, with irregularities, fluctuations or remissions. In 32 per cent of six hundred and fifty cases reviewed by Atkinson¹¹² glycosuria was mentioned. That this glycosuria or diabetes is due to hyperfunction of the anterior pituitary seems probable on the basis of various arguments formulated by Davidoff and Cushing⁶¹ (1) in these cases there is always an acidophile adenoma of the anterior pituitary. (2) diabetes usually does not occur in cases of chromophobe adenomas or other pituitary lesions, (3) pancreatic lesions are not constant in such cases, (4) partial extirpation of the tumors causes an improvement. (5) some of these cases are insulin resistant. (6) extirpation or irradiation of the pituitary lowers this resistance.

The histological changes in the pituitary in cases of diabetes have been studied with contradictory results and interpretations.^{156 167 196 12 22 206 261 262 265 4 9} It is probable that there is a pituitary factor in all cases of diabetes to a greater or lesser extent for example it is possible that it has a more important influence in cases of infantile diabetes, etc.

SUMMARY OF THE METABOLIC ACTIONS OF THE PITUITARY

The anterior pituitary has a tonic action on the basal metabolism since it develops and maintains the thyroids.

THE PITUITARY AND DIABETES*

Our experimental work has shown

(1) In the absence of the pituitary (or of the anterior lobe) pancreatic and phlorhizin diabetes is attenuated and animals retain and consume glucose.

(2) Anterior pituitary lobe extract counteracts the action of insulin increases pancreatic and phlorhizin diabetes etc.

The neuro-intermediate lobe regulates the secretion of water by the kidney (in amphibians and perhaps in mammals).

The anterior pituitary by its action on the thyroids and perhaps partly through other mechanisms, influences the concentration of iodine in the blood.

Colwell¹¹³ collected 25 cases. Davidoff and Cushing⁶¹ found it in 4 out of 108 of their cases, etc.
Resistance to insulin in a comatose has been found to be increased 200-250% by the anterior pituitary.^{141 1 322 323 324 325 326 327 328 329 330 331 332 333 334 335 336 337 338 339 340 341 342 343 344 345 346 347 348 349 350 351 352 353 354 355 356 357 358 359 360 361 362 363 364 365 366 367 368 369 370 371 372 373 374 375 376 377 378 379 380 381 382 383 384 385 386 387 388 389 390 391 392 393 394 395 396 397 398 399 400 401 402 403 404 405 406 407 408 409 410 411 412 413 414 415 416 417 418 419 420 421 422 423 424 425 426 427 428 429 430 431 432 433 434 435 436 437 438 439 440 441 442 443 444 445 446 447 448 449 450 451 452 453 454 455 456 457 458 459 460 461 462 463 464 465 466 467 468 469 470 471 472 473 474 475 476 477 478 479 480 481 482 483 484 485 486 487 488 489 490 491 492 493 494 495 496 497 498 499 500 501 502 503 504 505 506 507 508 509 510 511 512 513 514 515 516 517 518 519 520 521 522 523 524 525 526 527 528 529 530 531 532 533 534 535 536 537 538 539 540 541 542 543 544 545 546 547 548 549 550 551 552 553 554 555 556 557 558 559 560 561 562 563 564 565 566 567 568 569 570 571 572 573 574 575 576 577 578 579 580 581 582 583 584 585 586 587 588 589 590 591 592 593 594 595 596 597 598 599 600 601 602 603 604 605 606 607 608 609 610 611 612 613 614 615 616 617 618 619 620 621 622 623 624 625 626 627 628 629 630 631 632 633 634 635 636 637 638 639 640 641 642 643 644 645 646 647 648 649 650 651 652 653 654 655 656 657 658 659 660 661 662 663 664 665 666 667 668 669 670 671 672 673 674 675 676 677 678 679 680 681 682 683 684 685 686 687 688 689 690 691 692 693 694 695 696 697 698 699 700 701 702 703 704 705 706 707 708 709 710 711 712 713 714 715 716 717 718 719 720 721 722 723 724 725 726 727 728 729 730 731 732 733 734 735 736 737 738 739 740 741 742 743 744 745 746 747 748 749 750 751 752 753 754 755 756 757 758 759 760 761 762 763 764 765 766 767 768 769 770 771 772 773 774 775 776 777 778 779 780 781 782 783 784 785 786 787 788 789 790 791 792 793 794 795 796 797 798 799 800 801 802 803 804 805 806 807 808 809 810 811 812 813 814 815 816 817 818 819 820 821 822 823 824 825 826 827 828 829 830 831 832 833 834 835 836 837 838 839 840 841 842 843 844 845 846 847 848 849 850 851 852 853 854 855 856 857 858 859 860 861 862 863 864 865 866 867 868 869 870 871 872 873 874 875 876 877 878 879 880 881 882 883 884 885 886 887 888 889 890 891 892 893 894 895 896 897 898 899 900 901 902 903 904 905 906 907 908 909 910 911 912 913 914 915 916 917 918 919 920 921 922 923 924 925 926 927 928 929 930 931 932 933 934 935 936 937 938 939 940 941 942 943 944 945 946 947 948 949 950 951 952 953 954 955 956 957 958 959 960 961 962 963 964 965 966 967 968 969 970 971 972 973 974 975 976 977 978 979 980 981 982 983 984 985 986 987 988 989 990 991 992 993 994 995 996 997 998 999 1000}

*We have published paper on this subject in 1920-31 24

It maintains the potassium in the plasma at a normal level

It stimulates the endogenous protein catabolism and the protein minimum, particularly in fasting diabetes, etc

It has some influence on the nucleoprotein metabolism (stimulation of production of uric acid)

It has an action on the protein equilibrium of the plasma (through the thyroid)

It has a definite stimulatory action on ketonuria

Its action on the deposition and consumption of fats varies from species to species

In the absence of the anterior pituitary there is a great decrease in the excretion of sugar during fasting in diabetes and the new formation of sugar from protein is diminished

Hypophysectomized animals readily become hypoglycemic and may present grave symptoms and frequently die. Treatment with sugar produces spectacular improvements

Diabetes in hypophysectomized animals is less intense and they are able to utilize sugar. Excess of anterior pituitary lobe aggravates the diabetes or produces it in normal animals and causes a hyperglycemia which results in a poor consumption of glucose. It considerably increases the resistance to insulin in normal and hypophysectomized dogs. It has a direct action which is seen in the absence of the pancreas, gonads, thyroid or adrenals, etc

In pituitary insufficiency of the dog there does not appear to be an excessive consumption of glucose (low basal metabolism, normal respiratory quotient and glycogen). However, only a very careful study of the consumption of sugar in different animal species would definitely establish whether it is normal, increased or decreased. For fasting animals glycogen is low.

Without doubt the pituitary is one of the most important metabolic regulatory organs and in some species (in the toad particularly) it is of vital necessity. In the future it will be impossible to study any metabolic problem whether normal or pathologic, without reference to the pituitary. Growth endocrine regulation (including the reproductive functions) and metabolic regulation form the functional unity of the anterior pituitary gland.

CLINICS

The State Board of Health, Division of Maternity, Infancy and Child Hygiene is sponsoring a Maternity Clinic at the Laconia Hospital the third Wednesday of each month for expectant mothers who are not under the care of a physician Miss V M Jennings of Lakeport is the nurse in charge of the clinic

Four Tuberculosis Clinics have been started recently in Cheshire County Dr Robert B Kerr of Manchester will be the examining physician with Mrs Mildred Alken, County Tuberculosis Nurse, as sisting

An appeal for more persons in Cheshire County to take advantage of the free Cancer Clinics being conducted at the Elliot Community Hospital has been made by Dr Walter H Lacey, examining physician of Keene The State Legislature appropriated a sum of money for this work at its last session

The State Cancer Commission reports that since establishment of eleven clinics the first of January, 1934, doctors attached to the clinics have examined 1,152 patients Of this number, diagnosis showed that 39 per cent of those examined had cancer and treatment was prescribed

NURSES

Miss Maude Miles, Superintendent of the New Hampshire Memorial Hospital, has recently resigned her position Miss Miles plans to study this summer

The District Nursing Association and Portsmouth Red Cross are making plans to have a course in home nursing, classes to be held at the Portsmouth Hospital under the supervision of Miss Velma Pet-
 tiner, R.N The course will consist of twenty hours and will include such subjects as healthful home environments, care of the sickroom and patients, and feeding of the sick

The New Hampshire Graduate Nurses' Association held its quarterly meeting in Concord March 11, with Miss Ruth Whitcomb, R N, of Concord as Program Chairman Miss Claribel A Wheeler, R N, of New York City, Executive Secretary of the National League of Nursing Education, spoke at both morn-
 ing and afternoon sessions Miss Wheeler addressed the Association on "Curriculum as It Affects State Groups" Miss Margaret Riley, head of the Der-
 matology Department at the Massachusetts General Hospital, spoke to the Public Health section and Miss Alice E Jackson, Executive Secretary of the

Family Welfare Society spoke to the Private Duty group

HOSPITALS

The Laconia Hospital has recently acquired from one of its prominent physicians a McKesson Electric Oxygen Tent with which to treat pneumonia

PEDAGOGY

Governor H. Styles Bridges proclaimed Friday May 1 as Child Health Day. The slogan chosen for this year was "Health and Security for Every Child." In proclaiming this day as Child Health Day the Governor asked each community to take thought for its own needs and how they may be supplied and to give active and loyal support to the leadership in this regard of the Division of Maternity and Infancy of our State Health Department.

Dr. Anna Philbrook of the State Hospital in Concord spoke before the members of the Legion Auxiliary at Laconia April 15. Dr. Philbrook's subject was Child Welfare.

The Spring meeting of the New Hampshire Surgical Club was held at the Laconia Hospital on April 22. The morning session was devoted to a Dry Clinic. Luncheon was served at noon. Fifty-four members were present. Dr. Mark H. Rogers of Boston addressed the Club on Painful Shoulders, and Dr. Otto J. Hermann of Boston spoke on Compound Fracture Therapy.

DEATHS

CONNOR—HAROLD J. CONNOR, M.D., aged forty-five, one of the leading physicians of Concord and a member of the staffs of the Margaret Pillsbury and Memorial Hospitals, died at his home 41 Auburn Street on April 8, 1936. He had been ill for several weeks and his death was directly due to cerebral embolus.

Born in Woodstock, N. B., he received his medical training at Tufts College Medical School class of 1914. On August 5, 1917, he entered the military service enlisting in the National Guard Medical Corps and was stationed both at Salem and Boxford, Mass. He served in France from September 23, 1917, to April 4, 1919. At various times he was attached to the 101st Engineers, the 102nd Field Artillery and the 103rd Infantry and was discharged on April 28, 1919. He started his service as a first lieutenant and on September 16, 1918, was promoted to a captaincy.

Dr. Connor was married to Miss Mary Cragg of Concord, who survives him as do two children, Mary Louise and James.

BROOKS—HARLOW BROOKS, M.D. Word has been received of the death in New York City April 13, 1936, of Dr. Harlow Brooks, internationally known as a diagnostician and a summer resident of New Hampshire for several years. He was sixty-five years old.

Dr. Brooks, who was in great demand as a consulting physician and who numbered among his patients General John J. Pershing, Gerard Swope and Bishop William T. Manning, was stricken the Thursday preceding his death following his return to New York from Florida.

Dr. Brooks was the guest speaker at one of the annual meetings of the New Hampshire Medical Society several years ago. For the past thirty years, he had maintained a home in Raymond to which he returned for week ends and occasional weeks during the summer.

Dr. Brooks, who resided at 47 West Ninth Street, New York City, is survived by his widow, Mrs. Louise Davis Brooks, whom he married in 1899, and his daughter, Miss Ruth Brooks, who sailed for South America on April 2 with a scientific expedition.

NEW HAMPSHIRE STATE CANCER CONTROL

Local control of the cancer problem requires the co-operation of a fairly large group of interested people, a trained and competent directing authority and a supply of money sufficient to defray the expenses necessary to attain the planned objective. While the group of interested people will consist of both physicians and laymen, it is obvious that the major policies of development and procedure should be directed by physicians.

In May 1931 an act (Laws of 1931 Chapter 146) entitled "An Act providing for state aid for persons suffering from cancer and for the creation and appointment of a Cancer Commission," was passed by the New Hampshire Legislature. This act provides in brief for a commission of five persons with the governor as ex-officio chairman and the four appointive members to consist of two laymen and two physicians. One physician shall be a member of the State Board of Health and one to represent the New Hampshire Medical Society. These appointees have no definite term but serve at the will of the governor and council.

The act further provides that the commission shall establish and support cancer clinics, make studies and surveys of the cancer situation in the state, expend money for clinical care and assistance of poor and indigent cancer patients, partly on a fifty-fifty basis with towns and counties and partly outright. The commission may receive voluntary contributions for general or special purposes.

In visualizing the commission activities one must remember that New Hampshire is a small state with less than 500,000 inhabitants and with more than fifty per cent of them in the southern half of the state. Our fiscal year begins July 1 and our first years appropriation was for \$15,000. All but \$600 lapsed on account of inactivity. Since then the yearly appropriation has been from \$20,000 to that for this year and next of \$35,000 for each year.

The selection of the personnel of the commission was not completed until December 1931. During 1932 a survey of the state was made in an effort to ascertain the available resources for hospitalization and treatment and the number of cancer patients treated during the previous year. The commission felt its way carefully furnished aid to indigent patients through the facilities of the welfare department and in 1933 began to establish diagnostic clinics with the assistance of the established clinic or

Summary of paper read on March 1936 in New York City before the Office of Directors of the American Society for the Control of Cancer by George C. Williams, M.D. of March 1936. New Hampshire member of the New Hampshire Cancer Commission.

ganizations of the state health department. By November 1, 1933, there had been established eleven diagnostic clinics in general hospitals throughout the state and in 1934 this number was increased to thirteen. In 1934 and 1935, 1152 patients were examined at these clinics and positive cancer found in 451, or 39 per cent.

In 1933 and 1934 the commission, through the welfare department, expended \$16,623 for the care of terminal cases and for hospitalization of other indigent cases, and in 1935 there was expended \$16,097.40 for this purpose. The diagnostic clinic expense is approximately \$7,200 per year and the general administrative expense about \$5,300.

In 1935 the commission, having acquired information and experience through the cooperation with other departments, took over the entire management and supervision of state cancer control. In January, 1935, the commission established three treatment centers, in Manchester (Elliot Hospital), Concord (Margaret Pillsbury Hospital), and Hanover (Mary Hitchcock Memorial Hospital). At these hospitals there are available surgery, deep therapy x-ray and radium. The commission purchased 200 milligrams of radium and has allotted it to these three hospitals in such proportion as to augment the existing supply to 200, 100 and 100 milligrams respectively in each of the three institutions designated for treatment. This radium is available for free treatment of indigent patients, but may be used on other patients.

The present setup and activities of the commission, which have been and are being developed after two years of study and observation, are as follows:

- (a) An office in the State House with one lay member of the commission acting as secretary, assisted by one female clerk.
- (b) One field nurse who had been trained for several years in an active cancer treatment clinic. This nurse investigates all cases asking for aid and confers with county and town officials. She makes arrangements for hospitalization and nursing care of all indigent cases. She contacts each diagnostic clinic at regular intervals and follows up reluctant patients. It is expected that a general follow up system will be developed soon.
- (c) A comprehensive record of expenditures and an index of all cancer patients seen at clinics or cared for by the commission. A copy of clinic examinations is forwarded to this office for filing. A report of all radium and x-ray treatments at the treatment centers is also sent each month.
- (d) A monthly meeting of all members of the commission.

The activities carried on are divided into four fields of work:

- 1 *Conduct and Development of the Diagnostic Clinics.* This plan contemplates not only the examinations of patients presenting themselves at the clinics, but definite encouragement is given each clinic group to learn more about cancer, and to become more proficient in diagnosis. The greatly increased number of biopsies sent to the State Pathological Laboratory during the past two years attests to this increased efficiency. Physicians are invited to attend the clinics and are especially urged to accompany their patients. Closely related to diagnostic clinics are the three treatment

centers, each of these centers being also one of the thirteen diagnostic clinics. In these three centers the number of operations for cancer during 1935 has not been ascertained but 410 radium treatments were given to 277 patients. However, 370 of the radium treatments were given at the Elliot Hospital in Manchester. In addition to the three treatment centers there are two other hospitals in the state, the Laconia Hospital and the Notre Dame Hospital in Manchester, that have deep therapy machines and competent radiologists. This makes a total of five hospitals where deep therapy may be given. Four hundred and sixty-nine series of deep therapy x-ray treatments were given to 355 patients in New Hampshire during 1935.

Each fall the Cancer Commission, the directors of the clinics, the pathologists and radiologists have an all day conference and annually the radiologists meet for a separate conference.

- 2 *The Care of Poor Cancer Patients.* This includes investigation, transportation to hospitals for treatment, remunerating hospitals for board, care and treatment, placing terminal patients in nursing homes when necessary and supplying nursing and medical care. The commission pays all of the expenses for such care but is reimbursed for fifty per cent of the expenses by towns and counties when these patients are receiving public money for support. In addition to this class of patients, the commission may give the same assistance to unfortunate persons who are trying to pay their own way and are not able to assume the added expense of cancer care and treatment. Money expended on this latter class of patients comes entirely from the commission funds.
- 3 *Accumulation of Records,* from which may be deduced statistics of importance regarding the cancer situation in New Hampshire. The New Hampshire State Board of Health has contributed much assistance from its vital statistics department and also by ruling in 1935 that cancer be a reportable disease.
- 4 *Education.* Pamphlets are distributed at each clinic. All requests from clubs for speakers have been supplied. Numerous articles regarding cancer, and emanating from the Cancer Commission, have appeared in local papers. Since December 10, 1935, there have been weekly broadcasts, thirteen in all, on various phases of cancer education and information, sent out over Station WFEA in Manchester. These broadcasts, either complete or in abstract, have been printed weekly in sixty newspapers. Mimeographed copies of these broadcasts have been prepared and have been mailed in answer to requests. The commission is cooperating with the American Society for the Control of Cancer in the preparation of a state-wide educational campaign.

Owing to the fact that New Hampshire is such a healthful state to live in, we have a larger proportion of elderly people and to this fact is probably due the high incidence of cancer within the state. In spite of this handicap, the commission hopes to reduce this incidence in the next few years. The commission takes considerable pride in the fact that of

the 112 cancer clinics in general hospitals approved by the American College of Surgeons in the United States and Canada, the Elliot Hospital in Manchester was included in the number and of the forty seven provisionally approved hospitals the Margaret Pillsbury Hospital in Concord was included. The American College of Surgeons approved only thirty three diagnostic cancer clinics and in this group seven of the New Hampshire clinics were listed.

NEW HAMPSHIRE MEDICAL SOCIETY

HANDBOOK OF THE EARLY SIGNS AND SYMPTOMS OF CANCER

Prepared by the Committee on the Control of Cancer 1935

OBJECTS OF THE HANDBOOK

- 1 To furnish to the physician a summary of the available knowledge regarding the most important features of cancer because if cancer is recognized in its early stage and thoroughly and skillfully treated the majority of these patients should get well and in the more superficial group such as the skin and lip nearly all should get well.
- 2 To have at hand a convenient abstract for reference and as a reminder so that no patient will lose the best chances for life.
- 3 To enlist the co-operation of every practitioner of medicine in a real effort to reduce the deaths from cancer by curing the early cancer or the precancerous conditions.
- 4 To remind all physicians that a thorough physical examination on the patient's birthday and better each six months will enable him to recognize many early cancers or precancerous conditions that are now being neglected by the patient.

Committee on Control of Cancer

GEORGE C. WILKINS, M.D. *Chairman*

HOWARD N. KINGSFORD, M.D.

GEORGE F. DWIGHT, M.D. *Secretary*

CANCER OF THE SKIN

Cancer of the skin usually begins as a small painless scaly thickening or papule associated with crusts which are likely to fall off and then recur. This is followed by a warty or papillary growth associated with slight induration. It may then ulcerate with the development of hard everted edges, and a granulating base covered with crusts the removal of which causes slight bleeding.

Cancer of the skin may begin as a small, flat depressed thickening which ulcerates and enlarges.

Cancer of the skin may begin as a small pimple with persistent necrosis, and absence of inflammation.

It may begin as a cutaneous horn or may develop in a fissure or in the scar of an old burn.

Benign warts if irritated may become malignant.

A mole or wart, especially if increasing in size or beginning to form crusts or beginning to bleed must be thoroughly treated at once. Bluish black moles are especially dangerous because of the likelihood of metastasis and all of these should be removed by wide excision.

Cancer of the skin may be single or is likely to be multiple in old people who have senile keratoses.

Removal by excision, electrocoagulation or irradiation should be done at once and completely. Caustic applications are dangerous.

CANCER OF THE BREAST

Cancer is one of the most common new growths of the female breast, most likely to occur about the time of the menopause but may be seen in women of eighteen to thirty and in the very old. It is not uncommon to find the growth in unmarried women. About 1 per cent occur in men.

The growth appears insidiously and usually is found by accident while bathing or drying the skin. It may be found in any part of the breast. Absence of pain in the early cases is the rule although darting pain may occur.

The presence or absence of a tumor is determined by examining the breast with the flat hand with the patient in both the sitting and in the recumbent position. The characteristics of the tumor are best obtained by placing the patient in the recumbent position, stripped to the waist and while gently fixing the tumor with the thumb and index finger of one hand the tumor is examined with the index finger of the other hand. The least possible manipulation should be made and with the greatest gentleness. Every solid tumor in a woman should be looked upon as malignant, until proved benign.

Early cancer of the breast usually appears as a single, hard irregular painless lump. Its hardness may be masked by overlying fatty tissue. It may coexist with benign tumors and chronic cystic mastitis therefore multiple tumors often lead to an erroneous diagnosis. An attempt to lift the skin over the tumor may cause dimpling or depression. Bloody discharge from the nipple may be of diagnostic import and should be carefully investigated. It may be due to a duct papilloma or a duct cancer.

All detectable cancers are fixed in the breast tissue. Fixation to the skin or to the fascia of the pectoral muscle indicates advanced or late lesions. A visible tumor retraction of the nipple deformity of the breast, or ulceration of the skin suggests late cancer.

Hard painless discrete axillary nodes are an armatory of advanced cancer. The absence of nodes does not negative the diagnosis although it indicates a more favorable prognosis. Transillumination of the breast with an appropriate light in a darkened room or an x-ray of the breast and axilla by a competent roentgenologist, will be of aid in the diagnosis of breast tumors. According to our present knowledge cancer of the breast is best treated by radical amputation and irradiation. Rapidly growing cancers in young people far advanced cases and those which have metastasized to distant parts such as the lungs and the bones should rarely be operated upon except for the palliative removal of a large necrotic and foul growth.

Every suspected breast tumor should be freely excised and examined clinically and microscopically. No physician should "wait for developments, or tell the patient to not bother it until it bothers you." Tumors of the breast should not be rubbed or massaged.

CANCER OF THE LIP

Precancerous and cancerous lesions of the lip may result from excessive smoking hitting the lip or excessive exposure to the sun wind or cold over long periods of time such as occurs in farmers and sailors. Chronic dental infection is one of the most frequent causes.

Cancer of the lip may begin as a "fever blister" or a superficial crust fissure, ulcer or wart which may seem so simple to the patient that cancer does not enter his thoughts. Very similar lesions may have been present and may have disappeared earlier in life leading the patient to expect lesions at an older age to disappear also.

The important lesson to learn is that if a lesion of the lip does not show signs of disappearance within ten days or two weeks, it should be regarded as cancer until proved otherwise

The most distinguishing feature of cancer, though not the earliest, is the indurated edge or border which is due to the infiltrating character of cancer

With the knowledge now available, cancer of the lip like cancer of the skin, should be entirely eliminated

Disease in this area can always be recognized in its earliest stage by the patient, because the slightest gross change can be felt by the patient's tongue and can be seen in the mirror. In this early stage practically all cancers of the lip can be cured if treated skillfully and thoroughly at the beginning. Failures are due to delay, inefficient treatment, or to the application of some superficial irritating substance which causes congestion and increases the rate of growth. Silver nitrate or other escharotics should never be applied to questionable growths or ulcers

CANCER OF THE MOUTH

Cancer in the mouth as elsewhere in the body can be cured in the early stages. It can be seen and felt by the patient and the physician, and, therefore, the diagnosis can always be made early and thorough, skillful treatment should be applied at once

It is primarily a disease of elderly people but may occur in infants and children. It follows local irritation, leukoplakia, or syphilis, but may occur without any of these causes being recognized. The association with syphilis makes the prognosis less favorable

Chancres can be differentiated by finding the spirochetes. Gummas may be differentiated by biopsy. Cancer may occur associated with either of these lesions. A positive Wassermann test does not exclude cancer, should not delay treatment and a biopsy should be done

The early symptoms or signs are ulcer, induration, leukoplakia, with or without pain. The most common locations observed are the floor of the mouth, tongue, buccal surface of the cheek, soft palate and on the alveolar mucous membranes

To make the diagnosis is often difficult and commonly requires consultation. Each case is a law unto itself. The treatment cannot be standardized. The final outcome is dependent on the judgment used in planning the first attack upon the disease, and the plan will depend much upon the extent of the disease

CANCER OF THE LARYNX AND PHARYNX

The early symptoms are beginning hoarseness and local discomfort. The local discomfort may consist of a sticking sensation or a feeling of lump and tenderness during swallowing and frequently during phonation. If the vocal cords are involved, hoarseness is an early persistent symptom. If the growth does not involve the cords or is extrinsic, hoarseness will be a late symptom

The symptoms depend on the location and upon whether the lesion is an induration or ulceration or both

The responsibility of the physician lies in making an early diagnosis. In the event of suggestive symptoms developing the patient should be examined by a laryngologist experienced in detecting tumors and making biopsies. Repeated examinations are frequently necessary in early cases before diagnosis can be positive. The treatment is by surgical means, laryngofissure or laryngotomy, or by irradiation or both. Laryngeal cancer metastasizes fairly early

and patients should be examined frequently for the appearance of cervical nodes

CANCER OF THE LUNG

Cancer of the lungs or pleura is usually a metastatic growth from cancer elsewhere, but it may be primary. The earliest symptoms are cough and thoracic discomfort. If the pleura is involved, dyspnea due to fluid in the pleural cavity develops rapidly. The cough is frequently persistent and usually without expectoration unless it becomes bloody

The diagnosis can usually be made early by x-ray examination. The treatment is palliative

CANCER OF THE STOMACH

Of all the growths in the human body, carcinoma of the stomach is probably the most fatal and is probably the commonest of the internal cancers. One of the chief causes for error in diagnosis is failure of the attending physician to suspect its presence

It is essentially a disease of middle life, i.e., between forty and sixty years of age, rare, but highly malignant in the thirties

In most of the cases, premonitory symptoms are either slight or absent

There is no one striking symptom or group of symptoms by which it can be recognized as such in the early stages

The discomforts of the patient are commonplace, differing in no respect from indigestion, which can be accounted for by errors in diet, insufficient chewing of food, lack of teeth or dental infection, worry and overwork

The diagnosis is difficult or impossible from the early symptoms alone, but these indefinite symptoms that do not respond promptly to ordinary intelligent medical and dietary treatment, should suggest an immediate x-ray gastrointestinal examination which will usually determine the diagnosis

The early indefinite digestive symptoms become associated with anorexia, occasional vomiting to relieve distress, slight pallor, loss of weight and finally constant pain and a palpable tumor. Unexplained secondary anemia, with fatigue, suggests gastrointestinal malignancy

Of all diseases simulating carcinoma of the stomach, pernicious anemia and carcinoma of some other part of the gastrointestinal tract are the most confusing. Consideration of secondary symptoms and gastric ulcer may present problems in differential diagnosis

In the early stages a palpable mass is not present and gross hemorrhage is rare at any stage. Vomiting is neither an early nor a characteristic symptom. Induced vomiting to relieve distress is not uncommon in later stages. Low acidity of gastric contents suggests cancer, though free acid may be present

Any persistent or unexplained abdominal symptoms demand a careful gastrointestinal study especially by the x-rays

The treatment is surgical, and only early diagnosis can make surgical procedures advisable or successful

CANCER OF THE BOWEL

Of all the internal cancers, those of the bowel are most amenable to cure if the diagnosis is made at a reasonably early stage

Cancer of the small intestine is comparatively rare, contributing only 2 per cent of the bowel cancers

Of the remaining 98 per cent, about half are within six or eight inches of the anus, and the other half scattered throughout the colon

The most important and earliest symptom indicating the possibility of bowel cancer is the onset of

increasing constipation where none existed before or a definite and progressive increase in a previously mild constipation. Secondary symptoms may be colicky pain gas and borborygmi blood in the movements loss of weight secondary anemia and digestive symptoms.

Late symptoms are due to obstruction metastases loss of blood and toxic absorption. Alternating diarrhea and constipation as well as constant diarrhea, are late symptoms. Complete obstruction may occur with remarkable suddenness. All cancers of the bowel ulcerate and as this frequently occurs early a search for occult blood in the feces is a diagnostic procedure of great value. Blood and mucus in the stool are significant, though in cancer these constitute fairly late symptoms.

Any indication of the above picture should not be disregarded and a word of warning must be given regarding treatment. It is not only justifiable but advisable to investigate first, because in early bowel cancer it is possible so to amoliorate the symptoms by prescribing mineral oil and other medicines that clinical improvement satisfactory to the patient occurs, while the growth itself is growing constantly and constantly approaching the deadline of inoperability.

Reliable diagnostic measures are not difficult to apply and should always be used in the following order

1. Digital examination of the rectum. Nine tenths of all cancers of the rectum and therefore nearly one-half of all cancers of the bowels sit within reach of the finger.
2. Examination of the lower bowel with the proctoscope and sigmoidoscope. This allows inspection of six inches more of the lower bowel and also removal of biopsy specimens.
3. Barium enema and x ray examination fluoroscopically. This observation is checked with plates. Note that in cases of suspected cancer of the bowel where a complete gastrointestinal examination is contemplated the barium enema should be given first. Also methods (1) and (2) should be applied before any x ray methods are instituted.

The treatment of carcinoma of the bowel is surgical. Only in some cases of cancer of the rectum is radiation helpful and then chiefly in palliation.

Many cures result from adequate surgical treatment of cancers of the rectum and colon but this can occur only following early diagnosis.

CANCER OF THE UTERUS

Any woman who has a blood-tinted vaginal discharge bleeding spells between periods or any type of bleeding after the menopause should be examined with a very suspicious mind and all methods of diagnosis persisted in until accurate diagnosis has been made.

CERVIX

The earliest symptom is spotting usually disregarded by the patient. Excessive bleeding occurs only after cauliflower growths or destructive ulceration has developed.

Diagnosis can usually be made by inspection of the cervix through a speculum and with good lighting. Ulcers granulation tissue that bleeds freely after gentle wiping with a cotton swab or productive growths are all suspicious local indications of early cancer. When there is deep ulceration with fixation of the cervix or a large cauliflower growth palpation alone will establish the diagnosis.

In early cases the diagnosis can be accurately

made only by biopsy. The tissue should be removed from the edge of the ulcer or from the granulation tissue and placed in 10 per cent formolin solution.

Treatment of cancer of the cervix is by a combination of deep x ray therapy and radium.

UTERINE FUNDUS

Early symptoms are either a watery blood-tinted discharge or bleeding from the uterus between periods or after the menopause. In fundus cancer the bleeding is usually in spurts or at intervals though it may become continuous particularly after the menopause.

These symptoms call for an immediate pelvic examination and an examination of the cervix. If the cervix and vagina are free from disease a diagnostic curettage with pathological examination of the curettings must be insisted upon.

Diagnostic curettage should be performed under a general anesthetic and with aseptic precautions. The curettage should be gentle but every part of the uterine cavity should be covered in order that no small area of malignancy may escape detection. All curettings should be dropped in 10 per cent formolin solution and sent to the pathologist.

The treatment of cancer of the uterine fundus may be surgical plus radiation or radiation alone. This depends upon the duration of the disease the mobility of the uterus and obesity or general condition of the patient.

DIAGNOSIS OF BOWEL CANCER

The early diagnosis of malignant bone tumors is dependent upon the following essential factors

1. Malignant bone tumors may occur at any age.
2. Pain occurs early even before swelling or deformity localized directly to the point involved. That is there is definite localized tenderness. This may be differentiated from arthritic pains by pain or tenderness appearing above or below the joint but not in the joint. It may be differentiated from neuritis by the absence of other neurological symptoms.
3. Swelling or deformity usually without but occasionally with pulsation.
4. Roentgenographic examination. The final positive diagnosis is made only by an x ray examination. Sometimes on early lesion may require a second x ray examination after a varying interval to determine its character. An early diagnosis of malignant bone disease may mean a cure.

Be suspicious therefore of (1) old bone pains (2) unexplained bone swelling (3) atypical rheumatic pains.

CANCER OF THE BLADDER, PROSTATE AND KIDNEYS

1. Hematuria is a danger signal at all times. It is commonly due to a malignant condition of the urinary tract.
 2. Painful difficult and frequent urination demands a thorough examination.
 3. Rectal examination of the prostate should be a routine procedure.
 4. Cystoscopy and if necessary a pyelogram should always be used to establish and confirm the diagnosis.
 5. Pneumocystograms are useful in outlining the growth and in determining the degree of induration.
 6. Cancers of the bladder or kidney may occur at any age but rarely before the second decade.
- Cancer of the prostate is rare before forty. It is however on the increase between the ages of forty and seventy.

INFORMATION ON BIOPSIES

The most accurate method for the diagnosis of malignancy is the microscopic examination of a portion of the tumor in the hands of an expert pathologist

Details for performing biopsies vary with the individual situation some are performed with the scalpel, others with the electric knife, some by one or another of several punches which are on the market, and some by curettage. In any case a living and not a necrotic part must be removed, preferably with a bit of the surrounding tissue. Merely clipping off the surface of a tumor is not adequate.

The best fixative is 10 per cent formalin solution. The tissue should be immediately placed in a volume about ten times as great as the mass of tissue removed.

The grading of tumors either for prognosis or radiation sensitivity is of academic interest but in some locations aids greatly in indicating the best method of treatment and the amount of irradiation to be used. When a malignant tumor is present, everything possible should be done to eradicate it irrespective of histological grading.

Biopsy is of value in following the course of treatment—sometimes of critical value, and also, if properly done, it is harmless. Details of the history are

of importance to the pathologist in all cases, but particularly in those in which physiological activities are likely to be superimposed in and around tumors such as menstrual hyperplasias in carcinoma of the uterus. Occasionally a clinical diagnosis of malignancy is not sustained by the microscopical picture, whereupon a consultation with the pathologist is imperative. A slight margin of disagreement in diagnosis between quickly made frozen sections and regular sections still exists. This disagreement is of immediate practical importance only if it concerns malignancy versus nonmalignancy and not if a mere name for a tumor or other condition is in question. Tissues, unless too dense, can usually be prepared in twenty-four to thirty-six hours, but the diagnosis is too serious for uncertainty to be present because of poor preparations.

To summarize biopsies are harmless if done properly, they usually settle the diagnosis but pieces of tissues must be properly chosen for this purpose. They are also necessary in many cases to follow the course of treatment. The pathologist can be depended upon to use methods of preparation of his materials to ensure the quickest reports consistent with the accuracy demanded.

There is more danger from massage or repeated manipulation in making examinations, especially in cancer of the breast, than in doing a biopsy.

ESTIMATES HOSPITALS HAVE LOST 35,000
EMPLOYEES DURING THE DEPRESSION

Faced with a demand for services greater than at any time in their history America's hospitals, because of their financial condition, are being forced to function with a personnel reduced by 35,000, according to John Glossinger, vice-president of the Kny-Scheerer Corporation.

Mr. Glossinger bases his figure on a study made by the government of 6,112,529 cases on relief which revealed that in this number there were 20,000 who previously were hospital employees. Since the total number of United States unemployed is variously estimated as between ten and twelve million people, he said he believed that his 35,000 figure is conservatively correct.

The study brought to light one fact heartening to all friends of American public health, according to Mr. Glossinger. It proved that of over six million individuals on relief, only about fifty were physicians and surgeons. This compared with one thousand lawyers, three thousand ministers and religious workers and more than twenty thousand teachers.

Mr. Glossinger stated that May has brought two opportunities to hospitals to acquaint the general public with their work and with their needs. The first is National Hospital Day, observed on May 12, anniversary of the birth of Florence Nightingale and

the other is First Aid Week, which will be celebrated throughout the country May 17-23.

COMPULSORY HEALTH INSURANCE
IN CANADA

Current reports in the newspapers are to the effect that British Columbia enacted a bill March 1, 1936, which requires participation in compulsory insurance against illness by wage workers receiving less than \$1800 annually, except for farm workers.

Exemptions may be granted for domestic servants and certain other groups.

Contributions to the fund by employers are deducted from wages paid.

Benefits cover the wage earner, his wife and children, and include medical care by physicians, free public ward care in hospitals up to ten weeks, including obstetric service. Free laboratory service and diagnostic aids are provided and there is a cash maternity benefit for women who do not seek hospital accommodations.

Actuarial opinion was secured before the passage of the bill, but the plan is evidently on an experimental basis with the probability of adjustments to assure adaptability to conditions which may affect some features of the law.

The reactions to this law will be watched with interest in the United States.

CASE RECORDS

of the

MASSACHUSETTS GENERAL
HOSPITALANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL-PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., Editor

CASE 22201

PRESENTATION OF CASE

A forty-five year old American Negro pull man porter was admitted complaining of numbness and stiffness of the neck, shoulders and both arms.

Two years before entry the patient without previous injury, gradually developed stiffness and dull pain in the posterior cervical region radiating down both shoulders to the hands particularly on the right side. The discomfort was progressive and damp weather caused some exacerbation. Several months after the onset he remained in a hospital for two months during which time he was treated by means of baking lamps with considerable improvement. An x-ray at this time showed a "spot" in his spine which was said not to be tuberculosis. Thereafter he returned to work but the symptoms again returned to their previous intensity and he was unable to continue with his work. A year before entry he went to another hospital where a biopsy of a neck gland was done. This was diagnosed as tuberculosis and after a four weeks stay he was transferred to a tuberculosis sanatorium. He remained at this institution for about a month but became dissatisfied with his treatment and was therefore referred to another sanatorium. Here, after remaining on a tuberculosis ward for sixteen days he was informed that he did not have tuberculosis and was placed upon a general ward. He remained there for five months, during which period he developed anorexia and steadily lost weight. He returned home three and a half months before admission to this hospital. At about this time the pain in his neck gradually subsided and in its place there appeared a sensation of "numbness and pins and needles", especially down the right arm and on the anterior abdominal wall. Since the onset he had lost about seventy five pounds in weight and a proportionate amount of strength. For two months there was a cough productive of small amounts of white tenacious sputum, more marked in the morning. There was no blood streaking. He had no night sweats but often felt quite hot at night. There had been two attacks of "pleurisy"—one lasting for

six weeks at the onset of his illness and another in the left chest continuing only for several days nine months before entry. Up to a month and a half prior to admission the patient was ambulatory part of the time although there was some dyspnea with exertion. Thereafter he remained constantly in bed and became nervous, irritable, and slept poorly. Two days ago he became very weak and feverish.

Seventeen years before admission he had a persistent cold and for two weeks was confined to bed with rheumatism in the back.

Physical examination showed a well developed but thin, weak man who appeared chronically ill. The skin was warm and dry and over the lower end of the sacrum there was an early pressure sore. Oral hygiene was poor and the pharynx which was examined with difficulty, appeared negative. There was a 2.5 centimeter crusted wound just posterior to the right sternomastoid muscle. This was slightly tender and a small amount of yellowish pus was expressed from it. A walnut sized firm fixed, nontender mass was palpated just below the right mastoid process and several firm bean sized nodes were present in the posterior cervical region. There was marked limitation of motion of the spine in all directions in the cervical and dorsal regions. Only slight tenderness was elicited over the upper cervical region, but there was marked spasm of all the neck muscles posteriorly. There was slight scoliosis to the right in the lower cervical and upper dorsal regions. Much wasting of the chest and shoulder girdle muscles was noted. There was markedly limited expansion of the chest bilaterally. A soft fluctuant, slightly tender mass, measuring 10 by 8 centimeters, was found over the lower right scapula. The lungs were clear. The heart was normal. The blood pressure was 80/50. There was slight spasm and tenderness in the region of the left rectus muscle, most marked just below the umbilicus. No masses were felt. There was wasting and weakness of all the extremities, especially of the right arm and finger flexion was limited on this side. Deep tendon reflexes were active but slightly exaggerated in the left upper extremity. There was no Kernig sign but a right hand and a questionable left Babinski sign were elicited. Sustained ankle clonus was observed on the right.

The temperature was 99° the pulse 120. The respirations were 30.

Examination of the urine was negative. No Bencke-Jones protein was found. Examination of the blood showed a red cell count of 3,800,000 with a hemoglobin of 70 per cent. The white cell count was 8,500. 83 per cent polymorphonuclears. Repeated sputa examinations were negative for tubercle bacilli. Stool examinations were negative. A Hinton test was neg.

ative The serum protein was 5.2 grams per cent. The serum calcium was 8.5 milligrams per cent and the phosphorus 3 milligrams per cent. Creamy pus obtained from the abscess cavity on the back on one occasion showed four acid-fast bacilli. An intradermal injection of 1:10,000 tuberculin showed a one centimeter erythematous area with a raised center after forty-eight hours.

An x-ray showed the left diaphragm to be higher than the right and the lung markings were increased particularly on the right side. There was a slight lobulated widening of the supracardiac shadow. The heart and liver were not enlarged. The spleen was not seen. There was a small area of bone absorption near the vertebral end of the right first rib, destruction of the anterior and right lateral portions of the eighth dorsal vertebra, and an area of destruction in the fourth dorsal vertebra. There was a large soft tissue mass about the eighth dorsal vertebra, and a well-defined area of destruction in the left eleventh rib with a pathological fracture. The skull was negative. There were fleck-like areas of destruction in the middle thirds of both humeri and areas of destruction in the left side of the sacrum and wing of the ilium, the left ischium and right transverse process of the fourth lumbar vertebra. Films a week later showed a compression fracture of the second dorsal vertebra on the right side, an area of destruction of the second vertebra and a large soft tissue mass between the spine and pharynx extending from the base of the skull to the fifth dorsal vertebra. There were now multiple small shadows throughout both lung fields with widening of the superior mediastinum, more prominently on the right.

The patient's temperature fluctuated between 98° and 103° and his pulse between 90 and 130. He became progressively weaker, developed considerable difficulty in swallowing, and died on the twenty-second hospital day.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM B. BREED Now to go back over the history, we can discard at once any of the benign affairs of the back such as arthritis or rheumatism of various sorts, because as we read through the whole history we know this is a mortal disease and we must consider, therefore, mortal diseases. There is conflicting evidence, first he had tuberculosis and then he did not, then he had it, and then he did not. That history it seems to me makes one at least suspicious of tuberculosis. By that I mean there was enough evidence for such a diagnosis early in the disease to have him spend a good deal of time in a tuberculosis sanatorium. He had symptoms referable to some lesions in the spine with nerve root irritation which apparently progressed, and later on he was found to have ab-

cesses presumably emanating from the spine through the neck, perhaps retroperitoneally, and into the mediastinum. The appearance of the bones and ribs by x-ray is very confusing to me, and I think it throws me off a good deal from the diagnosis of tuberculosis. But if we leave the x-ray out, in a differential diagnosis tuberculosis must come first. I believe we can very easily rule out myeloma for two reasons. Bence-Jones protein is absent in the urine and the serum protein is not elevated. I hope we shall hear something interesting from Dr. Hampton about the x-rays.

Metastatic carcinoma might perfectly well cause this x-ray picture and I am not familiar with such an appearance caused by tuberculosis. These calcium and phosphorus figures were put in, I suppose, either to substantiate or eliminate some disturbance in the parathyroid because of the x-ray picture, but certainly there is no evidence of that. There is a low calcium and a normal phosphorus level which does not mean anything except possible debility and general cachexia before death.

I approached two x-ray men in this hospital and asked them if they recognized tuberculous osteomyelitis. I personally have not seen actual pathologic fractures and destruction of bone on the basis of tuberculous osteomyelitis. They said, "I am sorry but I cannot talk to you because I know about this case." So I ran away. Now I am wondering whether there is anyone here who can give me an unprejudiced opinion on this x-ray. If Dr. Hampton knows about this case I do not want to hear anything from him unless he can refrain from giving the show away.

DR AUBREY O. HAMPTON I will tell you what I said about the case before I did know.

The patient is a Negro. That is one of the important points of the x-ray examination and, furthermore, he has these lesions that were described in the report as multiple areas of bone destruction. Here is one in the rib. Here is a soft tissue mass surrounding the eighth dorsal vertebra which shows bone destruction. There is also bone destruction in the anterior body of the third cervical. Here is the trachea and larynx pushed forward by a huge retropharyngeal mass. I think you can see the extension of that swelling down to the ninth dorsal vertebra.

DR BREED That can perfectly well be a cold abscess?

DR HAMPTON Yes. They do produce destruction of the anterior margins of the vertebrae without destroying the joints occasionally.

DR BREED How do you explain the pathologic fractures of the ribs and the lesions in the middle of the humeri?

DR HAMPTON There is destruction of the vertebral margin of a rib including the pedicle of the vertebra. The pedicle, the transverse

processes and even a part of the laminae in the region of the second and third dorsal vertebrae have been destroyed. Here is the transverse process of the fourth lumbar vertebra, or what is left of it, it is also destroyed. This lesion here is probably the fracture in the rib that is described and it has united. I think you can see there the displacement of the trachea forward by the retropharyngeal mass.

DR. BREED: It says that there were fleck-like areas of destruction in the middle thirds of both humeri and areas of destruction in the left side of the sacrum and wing of the ilium.

DR. HAMPTON: I think that was bone atrophy as far as I can tell from this hasty examination. He had this lesion which may well have involved a portion of the brachial plexus and you would expect to get diffuse atrophy which would produce a fleck-like atrophy of the humerus.

DR. BREED: But not destruction?

DR. HAMPTON: I cannot be sure of that.

He also had something described in the upper end of the left femur here. He has atrophy in the upper end of the left femur, so I do not know that that is actually an area of bone destruction. I do not believe it is.

A PHYSICIAN: What about that left sacroiliac joint?

DR. HAMPTON: He has atrophy of the whole side of the pelvis and this is exaggerated but there certainly appears to be destruction there.

DR. BREED: It says here 'areas of destruction in the left side of the sacrum and wing of the ilium.'

DR. HAMPTON: I think this is the area described. It is not so obvious as some of the others.

There was a note which was rather inaccurate in the record and I think we owe a clarification of this to Dr. Breed. It says "a week later there were multiple small shadows through both lung fields with widening of the superior mediastinum, more prominently on the right." That is not quite accurate. They are more than multiple, they are numerous and very fine and rather dust-like in appearance, not military exactly because they are smaller than the usual military lesion.

DR. BREED: I do not want to ask you to do any more interpreting than you feel like doing.

DR. HAMPTON: I was shown all of these films, all except the chest, and I asked if the man was a Negro. I was told that he was, and it was from this information that I was able to make the diagnosis. I do not know whether I should tell you exactly what it was. I said that this x-ray appearance can be due to this disease in Negroes, Chinamen and Scotchmen.

DR. BREED: I appreciate that. I shall have to ask you about that later.

Of course, the question comes down here as

to whether we have to make one diagnosis or two and whether the whole thing can be explained on the basis of tuberculosis, which I think he had. There is a good deal of evidence for it: the past history seventeen years previously of persistent cough and 'rheumatism' in the back, and the story of progressive spinal lesions which are confirmed by the appearance of abscesses, and nerve root pain and soft tissue masses in the mediastinum. The thing of course that defeats me a little bit is this appearance of destruction of the ribs, this moth-eaten appearance and the pathologic fractures, on the basis of tuberculosis alone.

DR. HAMPTON: There was one other error in the x-ray interpretation. The record spoke of an increase in the mediastinal shadow but we have already explained the shadow as being paravertebral. It is not the mediastinum except as it occurs behind the trachea.

DR. BREED: It is a soft tissue mass that can perfectly well be a cold abscess from the spine. I hesitate to add any other diagnosis. Of course metastatic carcinoma will produce the picture in the ribs and in the other bones but we have no other evidence for it. He may have another disease but I think I shall be bold and attribute all the symptoms and signs to one disease—tuberculosis.

DR. TRACY B. MALLORY: Are there any other suggestions? Dr. Cave, what would an orthopedic surgeon think about it?

DR. EDWIN F. CAVE: I think it is the characteristic appearance of tuberculosis and the history and x-ray findings are both consistent with it. I think it is interesting that no joint is involved. It is purely a lesion of bone and not of the joints. You usually think of tuberculosis as being a joint affair as much as a skeletal one. I think I should agree with Dr. Breed that the diagnosis is tuberculosis and nothing else.

DR. MALLORY: Dr. Bock, you actually saw the patient, will you give your impression?

DR. ARTHUR V. BOCK: We felt exactly as Dr. Breed did, that the bone lesions were not characteristic of tuberculosis, in spite of what Dr. Cave says, that they were more consistent with the picture that one might have from such a condition as metastatic carcinoma. Against that, however, was the very obvious retropharyngeal abscess extending down into the chest giving him increasing difficulty in swallowing, a condition that we thought would be very unusual except as secondary to tuberculosis of the spine. We decided on this basis that the underlying condition must be tuberculosis in spite of the queer appearance of the other x-ray findings. We finally felt that he had a military process. He reminded me very much of a patient in the Baker Memorial a few years ago who had a prolonged illness with fever and very little specific symptomatology. She had malaise, weakness and

fatigue unassociated with any febrile state. She had had x-rays of most of the skeleton and the x-ray department said she had widespread metastatic malignant disease. There had been no x-ray visualization of cervical spine though she gave a history of having distress on swallowing. The x-ray of the neck showed a lesion somewhat like the one in this case and she had a retropharyngeal abscess which had penetrated through the posterior mediastinum to the diaphragm, all due to tuberculosis, the x-ray picture in the bones generally was later interpreted as the result of atrophy from long bed confinement.

DR GEORGE W. VAN GORDER: I happened to have seen this patient in consultation, and felt that if one looked at the x-ray picture alone, the most likely diagnosis would be metastatic carcinoma. You can pick out single lesions in the x-ray which are identical in appearance to metastatic carcinoma.

But when you look at the clinical picture and realize that these bone lesions are associated with cold abscess formation and that the patient has a large retropharyngeal abscess resulting from destruction of the cervical vertebrae, then I am sure most of us would favor the diagnosis of tuberculosis in preference to carcinoma. I was wondering if any lesion could produce these signs and symptoms, such as actinomycosis, because, as Dr. Bock has said, the lesions in the bone are not at all typical of tuberculosis since they affect the bodies of the vertebrae and the shafts of the ribs rather than joint structures. If it is tuberculosis, which seems most likely, it is certainly an atypical form of the disease.

DR HAMPTON: I hoped that Dr. Van Gorder would tell you of his cases of bone tuberculosis occurring in the Chinese. We have had two other Negroes in this hospital with extensive bone tuberculosis similar to this case. Bone tuberculosis is common in Scotland. There is one other infectious disease which might produce this whole picture, coccidioid granuloma and I think that if the patient had come from California we would have strongly suspected coccidioid granuloma.

CLINICAL DIAGNOSIS

Tuberculosis of the spine, glands and lungs

DR WILLIAM B. BREED'S DIAGNOSES

Tuberculosis (miliary) of lungs, spine, ribs and long bones

ANATOMIC DIAGNOSES

Tuberculosis of the spine, multiple foci
Paravertebral and epidural abscesses, tuberculous
Tuberculous pachymeningitis

Tuberculous lymphadenitis, bronchial
Tuberculous pericarditis with synechia
Tuberculous myocarditis and endocarditis, right auricle
Tuberculosis of the ribs
Acute miliary tuberculosis, terminal

PATHOLOGIC DISCUSSION

DR MALLORY: We found at autopsy multiple tuberculous foci throughout the vertebral column. There were two cervical and three dorsal vertebrae, particularly severely involved with compression fractures, as you can see at the midpoint of the specimen there. In a great many areas pus seemed to be exuding from the vertebral column in all directions, front, back, and sides. Why there were symptoms of referred pain in some areas and not in others was rather difficult to guess from the autopsy, because it looked as though the great majority of the spinal nerves were involved. In the cervical spine there was a definite epidural abscess and the dorsal roots were bathed in pus.

The other interesting and entirely surprising feature of the autopsy, there was nothing in the clinical history to give a lead to. The pericardium was completely obliterated by an extensive tuberculous process, evidently direct invasion from a tracheobronchial lymph node. The process had first obliterated the pericardial space and then had actually invaded the wall of the heart, so that in the right auricle the tuberculous process passed completely through the musculature of the auricle and there was an actual tuberculous endocarditis, if you want to call it that, of the intima of the right auricle. There was finally a terminal generalized miliary tuberculosis. What the course of events was here, we were not able to determine from the autopsy. The lesions in the spine appeared as old as those that we found anywhere else in the body. There was no evidence of any primary tuberculous infection in the lung.

A PHYSICIAN: I should like to ask whether there was any adrenal involvement, and whether he had any evidence of amyloid disease?

DR MALLORY: Neither. The adrenals queerly enough did not show miliary tubercles.

DR GEORGE W. HOLMES: Can you tell whether the pericardial lesion was old or recent?

DR MALLORY: It was fairly old undoubtedly.

A PHYSICIAN: Were the bones of the extremities x-rayed?

DR MALLORY: No, we did not examine those. The ribs showed atypical tuberculosis.

DR CAVE: Do you think the appearance of the vertebral bodies was due to intrinsic disease or to pressure from the abscess?

DR MALLORY: Probably in part from both. Sections of the vertebral bodies showed older and younger tubercles scattered throughout and some of the lesions undoubtedly were primary.

in the vertebra. On the other hand, the vertebrae behind the cold abscesses showed erosions of their anterior margins which I am sure were secondary.

CASE 22202

PRESENTATION OF CASE

First Admission. A twenty-one year old Armenian dancing instructor was admitted complaining of jaundice and fever.

For two years the patient had had many bouts of fever persisting for two to four days and occurring at about two week intervals. At the onset, while still in Armenia following a severe chill he had been treated in a hospital for what was said to be malaria. Soon after discharge he immigrated to this country. Since that time there were no chills but he had profuse perspiration following fever. He was not confined to bed during his febrile periods. Two weeks before entry he had an attack persisting for five days during which he first noticed the presence of jaundice. The icterus subsided with the pyrexia but recurred two days prior to entry when he again became feverish. His temperature had not been taken since his initial illness but he had taken quinine with each febrile spell. There was some anorexia but no abdominal discomfort, nausea, emesis, bowel irregularity or respiratory disturbance. He noted that his urine was reddish during each attack.

Physical examination showed a well developed and nourished young man with a deep icteric tint of the skin and sclerae. The heart was normal. The blood pressure was 104/80. The lungs were clear. The abdomen was soft and the liver dullness extended from the sixth rib to a point just beneath the costal margin. The spleen was not palpable. No tenderness was elicited.

The temperature, pulse and respirations were normal.

Examination of the urine showed a specific gravity of 1.026 with a trace of albumin and a positive reaction for bile. The sediment was negative. Examination of the blood showed a white cell count of 7,800, 72 per cent polymorphonuclears. The hemoglobin was 85 per cent. The stools contained bile and examination showed no blood pus, fat or parasites. A blood Wassermann test was negative.

X-ray examinations of the gallbladder region and teeth were reported as normal.

For a month after admission the patient remained afebrile. His jaundice gradually subsided except for a single exacerbation two and a half weeks after entry. On the thirty-sixth hospital day his temperature suddenly rose to 102.5° and the jaundice again became deeper. At this time the edge of the liver became palpable and was reported to be smooth and tender. The tip of the spleen was also felt. On two suc-

ceeding days he had an irregular fever fluctuating from 98° to 102°. Several times a severe chill preceded the rise in temperature. An echinococcus complement fixation test was negative at this time. Thereafter the temperature returned to normal and on the sixtieth hospital day a cholecystectomy and a choledochostomy were done. At operation the gallbladder was found to be thickened and this process was said to extend to the common duct. The liver was small and nodular. A probe was passed through the common duct into the duodenum without difficulty. Postoperatively the patient exhibited scanty drainage of bile but otherwise responded fairly well and was discharged on the eighty-second day. No note was made of the degree of jaundice at this time.

Second Admission, six years later.

Following his discharge the patient felt weak for several weeks and then gradually regained his strength. There was no recurrence of his fever chills or jaundice and he had no further symptoms until six months before re-entry. At this time he first noted that his abdomen was slightly more prominent than usual. This abdominal swelling progressed very gradually and three and a half months later he developed pain and swelling in the left ankle. This continued for about two months and then subsided spontaneously shortly before his readmission to the hospital. He had no symptoms referable to his gastrointestinal tract.

A brother had developed jaundice at approximately the same time as the patient six years before. This persisted and, except for pruritus, was associated with no other symptoms. At the end of six months, the icterus having continued, the brother had a cholecystectomy performed. He responded poorly postoperatively and died one month later after a stormy febrile course.

Physical examination showed a poorly developed fairly well nourished man in no discomfort. There was a questionable icteric tint to the sclerae. A few shotty nodes were palpated in the right axilla. The heart was not enlarged but a loud blowing systolic murmur was audible in the pulmonary area. The blood pressure was 92/50. Both sides of the chest were dull to percussion posteriorly up to the angles of the scapulae. Few coarse rales were audible at the angle of the right scapula. The abdomen was tender and rounded. Shifting dullness and a fluid wave were obtained. The liver dullness extended from the fourth interspace to a point two finger breadths beneath the costal margin. The edge of the spleen extended two centimeters beneath the costal margin with inspiration.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. The blood showed a red cell count of 3,250,000 with a hemoglobin of 65 per cent. The white cell

count was 3,250, 70 per cent polymorphonuclears. A stool examination was negative. A van den Bergh test gave an indirect reaction and showed 1.7 milligrams per cent of bilirubin. A red blood cell fragility test showed hemolysis beginning at 0.38 and complete at a saline dilution of 0.28. An icterus index was 5. A liver function test showed 5 per cent retention after thirty minutes.

With a low base diet, ammonium chloride and novasurol the patient developed an adequate diuresis, lost ten pounds and was relieved of his ascites. He was discharged on the fourteenth day.

Third Admission, seven and a half years later, at the age of thirty-five.

Following his last discharge the patient had slight swelling of his ankles for about two years and there was no evident recurrence of the abdominal swelling. Thereafter he remained symptom free until the morning of his re-entry. At this time he was awakened by an agonizing nonradiating pain in his right side just under his ribs. The pain was not increased by respiratory movement or walking. An enema produced no fecal return and shortly afterward he vomited about two cups of greenish material. This was followed by four brief but severe chills. He noted a slight burning dysuria. Four hours after the onset the attack ceased abruptly.

Physical examination showed a slightly emaciated pallid man in no discomfort. The tongue was smooth and pale and the pharynx was slightly injected. The heart was not enlarged. A soft systolic murmur was heard at the apex. The blood pressure was 120/50. The lungs were clear. The abdomen was slightly distended and shifting dullness was elicited in the flanks. Liver dullness extended from the fifth interspace to the costal margin. The spleen was moderately enlarged. Rectal examination showed the presence of external hemorrhoids.

The temperature was 100.5°, the pulse 90. The respirations were 25.

Examination of the urine showed a specific gravity of 1.012 with a slight trace of albumin. The sediment contained a few white blood cells and was loaded with red blood cells. The blood showed a red cell count of 3,030,000 with a hemoglobin of 60 per cent and a volume index of 1.16. The white cell count was 3,000. A van den Bergh test showed 3.15 milligrams per cent of bilirubin. A serum cholesterol was 150 milligrams per cent. The serum protein was 5.4 grams per cent. The nonprotein nitrogen of the blood was 24 milligrams per cent. A phenol-sulphonaphthalein test gave 85 per cent excretion at the end of one hour. The venous clotting time was nine to ten minutes. The liver function was recorded as 10 per cent.

X-ray examination showed the right kidney outlines to be normal. The left kidney was a

little low in position and rather broad across its mid-portion. There was a crescentic area of calcification lying just to the right of the first lumbar vertebra and a second calcified area overlying the eleventh rib over its vertebral articulation. Except for thickening of the hilar shadows and a slightly heightened left diaphragm the chest was negative. Examination of the esophagus showed the presence of varices. An intravenous pyelogram showed prompt appearance of dye on both sides. There was an anomalous configuration of the left kidney. There was no evidence of stone. The calcified areas were evidently outside of the genitourinary tract.

The patient was treated palliatively and given parenteral liver extract. His temperature returned to normal on the second day and remained normal thereafter. The hematuria continued but lessened to 20 red blood cells per field. The patient was discharged on the ninth day.

Final Admission, two months later.

He returned to normal activity following his last discharge and four weeks before readmission he began to notice evening swelling of his ankles which was relieved by bed rest. A week later the ankle swelling persisted and his abdomen gradually became enlarged. This produced some generalized abdominal discomfort but no actual pain. Occasionally he had fleeting joint pains which were not associated with local swelling or redness. His appetite was good and his bowel movements were regular but pale yellow. His urine became scanty and dark brown in color.

Physical examination showed a slightly jaundiced, thin man in no discomfort. Dullness was elicited in both chests from the fourth ribs anteriorly and the angles of scapulae posteriorly to the bases. The breath sounds were absent here. The heart findings were not noted. The abdomen was tense, bulging, and the umbilicus pouted. There was edema of the penis and lower extremities.

The temperature was 98°, the pulse 110. The respirations were 25.

The urine contained a large amount of bile but the sediment was negative. The blood showed a red cell count of 3,570,000, with a hemoglobin of 75 per cent. The white cell count was 4,600, 91 per cent polymorphonuclears. The stools were greenish in color but otherwise negative. The blood cholesterol was 166 milligrams per cent and the serum protein 4.9 grams per cent. The van den Bergh showed 6.26 milligrams of bilirubin.

Three thousand cubic centimeters of clear amber fluid was removed by abdominal paracentesis. This showed a specific gravity of 1.010, a total protein of 0.8 grams per cent, and contained 2,260 cells per cubic millimeter, of which

2000 were red blood cells. The patient was treated with intravenous glucose, repeated transfusions, mercurial diuretics, and abdominal taps with resultant diuresis of a moderate degree and a weight loss of twenty pounds. Several febrile episodes occurred, the first of which was associated with a tender reddened swelling in the right Scarpa's triangle. Later rales appeared in the right axilla and subsequently there developed an area of dullness with bronchial breathing in this region. At the end of one month his temperature began to show a daily fluctuation between 98° and 100° with occasional rises to 103°. The serum bilirubin content remained unchanged at 6.85 milligrams per cent. On the forty-first hospital day the patient's temperature rose to 104° and on the following day a brown indurated swelling appeared on the face and assumed a somewhat symmetrical butterfly appearance. The lesion spread peripherally and presented a rather sharp raised edge. The white blood cells rose to 15,000 and the temperature fluctuated between 99° and 105°. Thereafter he went rapidly downhill and died on the forty-fifth hospital day, four teen years after his initial entry.

DIFFERENTIAL DIAGNOSIS

DR. WYMAN RICHARDSON. The story on the first admission makes one think of paroxysmal hemoglobinuria, hemolytic jaundice and biliary cirrhosis as possible diagnoses. We might add to that the possibility of quinine susceptibility in malaria, but as we go on I think there is very little evidence for the diagnosis of malaria.

"The abdomen was soft and the liver dullness extended from the sixth rib to a point just beneath the costal margin." The liver therefore does not appear to be large if anything it is small. The spleen is not palpable which is opposed to a diagnosis of hemolytic jaundice.

"Examination of the urine showed a positive reaction for bile." Bile, as such, would not be present in the urine from hemolytic jaundice. It is not an obstructive jaundice, however as there is bile in the stool.

"A blood Wassermann test was negative." That is against a diagnosis of paroxysmal hemoglobinuria, also the presence of bile in the urine against that diagnosis.

"At this time the edge of the liver became palpable and was reported to be smooth and tender." A large liver in hemolytic jaundice is also said to be quite rare.

One can question why operation was done. I assume that this patient probably had a biliary cirrhosis from the story thus far and very likely they felt that the infection was coming from the biliary tract. The cholecystectomy with drainage of the biliary tract might help to overcome that infection. I cannot see any

evidence for gallstones or any other disease that in itself requires operation. The findings at operation are not those of ordinary biliary cirrhosis which usually is associated with an enlarged liver.

"A brother had developed jaundice at approximately the same time as the patient, six years before." The problem is whether he had the same disease that the other brother had. As far as hemolytic jaundice goes, it may be familial, of course, but the story does not suggest hemolytic jaundice and I do not see how his brother had it. In regard to the familial evidence of infectious biliary cirrhosis I have a vague remembrance that it may occur in more than one member of the family but I cannot remember, nor can I find it in any common text.

I do not know how one can percuss liver dullness in an abdomen full of fluid. I am rather surprised at that. These symptoms that appear in the second admission are the first ones of a beginning difficulty with circulation through the liver and a beginning cirrhotic liver.

"The white cell count was 3,250 with 70 per cent polymorphonuclears." With the leukopenia this is rather strange because it shows seventy per cent polymorphonuclears. Usually leukopenia is due to reduction in neutrophils.

"A stool examination was negative." I take it that means there was bile in the stool.

The blood findings are not very characteristic of anything. The blood smear is not described. We assume he has a beginning cirrhotic process in the liver and it would be perfectly all right to explain the blood picture on that basis. Whether it is a macrocytic anemia or not is not stated.

"With a low base diet ammonium chloride and novasurol the patient developed an adequate diuresis, lost ten pounds and was relieved of his anasarca." That was about six or eight years ago. I remember about that time we found that you could produce a diuresis in cirrhosis of the liver by giving ammonium chloride and novasurol, or salyrgan.

It is a little difficult to explain that attack of pain on any other basis than on the basis of liver pain. Just what the mechanism of pain is in these cases, I do not understand but we know one can get pain in catarrhal jaundice and in cirrhosis of the liver and other liver conditions without being able to explain the exact mechanism of the pain.

"The abdomen was slightly distended and shifting dullness was elicited in the flanks. Liver dullness extended from the fifth interspace to the costal margin." The liver seems to be shifting back and forth all the time.

"The sediment contained a few white blood cells and was loaded with red blood cells." You can occasionally get hematuria in cirrhosis of the

liver, at least in portal cirrhosis of the liver, and I am explaining the hematuria on the basis of liver disease

The blood picture seems to be a macrocytic anemia now. The white count is 3,000. The picture is perfectly correct for pernicious anemia, also for advanced liver disease. The interesting thing about the anemia of liver disease, which sometimes looks like pernicious anemia, is that it is often very difficult to treat. One would think that advanced liver disease might destroy enough of the active principle so that these patients would develop pernicious-like anemia. However, if this were so why do they not respond to liver therapy?

X-RAY INTERPRETATION

DR GEORGE W. HOLMES: There were many x-ray films, some are quite interesting. The films of the esophagus show considerable widening of the esophagus and some delay in the passage of barium through it, and the lines here, which show better in the smaller film, are quite characteristic of esophageal varices. Here is another film showing the worm-like lines of rather large varices. It is interesting that when the esophagus is full you cannot see them. They show much better when the esophagus is empty. The films taken of the stomach I think show rather prominent gastric rugae. As you would expect in this case, the stomach is high and empties rapidly into the small bowel.

In these films of the urinary tract you can see the outline of the left kidney here. It is a bit unusual for the left kidney to be lower than the right. The left kidney is larger and lower than the right and definitely abnormal in the upper pole. The kidney pelvis is displaced downward and outward. This shape of the kidney itself seems to be abnormal, as though there were a mass in the upper pole of the kidney.

DR RICHARDSON: Could it be overlying spleen?

DR HOLMES: No, I do not believe so. The spleen might push the kidney down and the small liver might allow the right kidney to be high, but I do not believe a large spleen would give you this shape or distort the kidney pelvis.

Here is the crescentic shadow described. It appears to be below and outside the kidney. I do not believe it is part of the kidney shadow.

This shadow at the eleventh rib could be due to calcification in the wall of an aneurysm. It seems to be constant and it is not part of the kidney.

We have a film of the chest which shows a relatively high diaphragm on the left. The heart shadow is slightly increased and the hilus vessels are prominent but there is nothing else.

A PHYSICIAN: Is that calcified and elongated enough to call pathologic?

DR HOLMES: No, I think it is more anatomical.

DIFFERENTIAL DIAGNOSIS CONTINUED

DR RICHARDSON: I have explained the calcified area as perhaps calcification in a hematoma resulting from the previous operation, although there was no evidence of hematoma at that time, and that is the way I am going to leave it. In regard to the kidney I am going to say it is a red herring and it is probably a congenital abnormality. Would that be consistent with the x-ray interpretation?

DR HOLMES: That is a possibility.

DR RICHARDSON: I am not going to pay any attention to it. We shall see later.

I have not paid any attention to the joint pains. I think it was a toxic reaction and partly due to swelling of the legs.

He has now, as you will see later, an increasingly low serum protein, so that he is perfectly entitled to edema anyway.

The problem of leukopenia in this patient, with cirrhosis of the liver, with large spleen is interesting. I do not know whether there is any definite relationship in these cases between the spleen and the leukopenia.

"The stools were greenish in color but otherwise negative." That is suggestive of biliary type of cirrhosis.

It is rather complicated working out everything here and I am going to stick to what I think was the essential disease this man had. He was a young man who lived for thirteen and a half years following his first attack of jaundice. I am going to rule out all rare tropical diseases. I do not know enough about them to talk about them, and it certainly is not malaria. He has recurring jaundice with fever, jaundice that is not obstructive and associated sometimes with greenish stools. He had splenomegaly and a long chronic history. These things spell to me infectious biliary cirrhosis. It is rare to get edema in biliary cirrhosis but I am sure as the process goes on you get secondary fibrosis and rarely a cirrhotic process in the liver. All the symptoms can be explained on that basis except possibly the hematuria and this question of the kidney. I am going to say it is not an important feature in this disease. I think he died of erysipelas. I think it is quite possible that Dr. Mallory will find acute vegetations on the valves of the heart, although there is not much evidence to go on there. Dr. Mallory is very much inclined to turn up a neoplasm in these cirrhosis cases but I do not believe he is going to this time. So that I will say he has biliary infectious cirrhosis with a terminal erysipelas and a question as to whether there may be a terminal acute septic endocarditis. I think

the calcification here was from an old hematoma. As to what the kidney is going to look like I do not think I will say.

Dr. TRAUB B. MALLORY I think perhaps we should have given Dr. Richardson one other piece of information, which those of us who followed this patient all knew. The patient's brother died and was autopsied in this hospital nearly fifteen years ago a few months after the onset of his illness. He showed a very atrophic grossly nodular liver that could be described as either subacute atrophy or rather rapid cirrhosis. I do not know whether that makes him want to change his diagnosis.

Dr. RICHARDSON I am not going to say any more. I have said too much already.

Dr. MALLORY Dr. Jones you followed this patient for fifteen years and know him better than anyone else.

Dr. C. M. JONES He represents a very unusual picture of chronic liver disease apparently starting with a clean cut attack of catarrhal jaundice, the brother developing the same type of hepatitis within a week. I have forgotten which came first. I believe this man was first and the brother a week later. Both of them were in the ward under the care of Dr. W. D. Smith at that time, and while on the ward the jaundice increased during the period of a month to two months. The feeling was that the symptoms were due to intrahepatic disease and that possibly if we could provide more adequate biliary drainage they might improve. I do not think we would perform the operation on a similar case now. It would be interesting to see what Dr. Vincent says. At that time we thought it wise, and in this particular instance operation was performed by Dr. Vincent and there was reduction in jaundice following that operation. The brother, who had an identical condition was operated on I think four months after the onset. He went out of the hospital after his first admission and then returned for operation because he was getting worse but the operation was followed by a relatively short survival period. At operation in each instance the liver showed what would appear to be grossly the results of a subacute yellow atrophy with regeneration. Both livers were nodular although the nodules were relatively small. This patient that we are discussing today was jaundiced for about a year if I remember correctly but it finally diminished until it no longer played a part in the picture. The next symptom of importance and what interested me most was the development of ascites and edema. He came in to see me because his feet were swollen, he could no longer give dancing lessons and it was obvious he had ascites. He was given a course with novarsol and was then free from ascites for many years. I think possibly that is the

most important point to be gained from the discussion of this case. Here was an individual with chronic liver disease undoubtedly infectious in origin, with liver damage and regeneration who subsequently developed enough hepatic insufficiency so that he developed ascites. As a rule if we have edema with it when ascites develops it is pretty close to a terminal event. In this case following rest and adequate treatment with a diuretic his ascites disappeared not to recur for at least six years, when he came in again with swelling of the abdomen. I think it is increasingly true as we watch these cases that the prognosis is very difficult to make correctly and even with marked ascites one can be more optimistic than statistics would have us believe. This man earned his living following the disappearance of ascites, until a few weeks before he came into the hospital this winter. During the past three years one other symptom has been of some interest and that is, that he had a very intractable anemia. The red count for the most part had stayed in the low three millions and it was impossible with massive doses of iron to alter it very much. I think that spells a high degree of liver insufficiency with inadequate reformation of hemoglobin. In spite of that he was able to carry on until the terminal event namely, return of ascites and edema, and subsequently an intercurrent infection which he could not resist.

There is a case on Ward D at the present moment which is of some interest. He is now going through exactly the same cycle, ascites and jaundice and appeared to be recovering very satisfactorily until he picked up a streptococcus infection and erysipelas. He very nearly failed to survive it but is improving again at the present moment. It seems that these people with liver damage of any degree stand ordinary infections very poorly. The picture—Dr. Mallory will give us that—started with catarrhal jaundice. I think it is not fair to say infectious biliary cirrhosis because almost all liver changes that take place in relation to catarrhal jaundice are in the nature of acute yellow atrophy with regeneration leading to another type of cirrhosis, so-called toxic cirrhosis. I believe that is what he showed at autopsy.

Dr. WILLIAM D. SMITH I saw this man once thirteen years ago and strangely enough I remember him probably because there were two of them. His brother was also a very interesting case. I remember that the feeling of the staff at that time was that he did have a biliary cirrhosis and although Dr. Vincent operated on him I remember Dr. Daniel Jones coming by on the ward and advising operation for exactly the same reason that Dr. Richardson gave this morning. Some cases of biliary cirrhosis with infection of the intrahepatic

ducts are questionably improved by drainage of the common ducts

I do not believe we were thinking quite so much fifteen years ago about healed acute yellow atrophy and I think in view of what we know now, and in view of the fact that the liver of the first brother to be operated on was small and nodular, one would have to consider pretty seriously healed yellow atrophy or toxic cirrhosis with portal obstruction

DR BETH VINCENT A number of years ago we explored a certain number of these infectious jaundice cases in the hope that if we found a lesion of the gallbladder we could remove it, institute drainage and favorably influence the course of the disease. Although this man lived a long time and had periods of good health we came to the conclusion that we had not accomplished anything in this case or in any of the other cases. We decided that it was not only a procedure without benefit but in certain of the cases it might be a procedure of very considerable risk, so we gave it up

CLINICAL DIAGNOSES

Cirrhosis of the liver, cause undetermined
Erysipelas of the face

DR WYMAN RICHARDSON'S DIAGNOSES

Infectious biliary cirrhosis of the liver
Erysipelas

ANATOMIC DIAGNOSES

Cirrhosis of the liver, toxic
Ascites
Esophageal varices
Icterus of the skin, marked
Erysipelas of the face
Peritonitis, acute fibrinous (sterile)
Splenomegaly
Pulmonary edema, bilateral

Operative wounds Cholecystectomy, old,
and abdominal paracentesis
Lymphadenopathy, retroperitoneal glands
Ulceration of the stomach, slight
Edema of the extremities, slight

PATHOLOGIC DISCUSSION

DR MALLORY The autopsy on this man showed an atrophic liver weighing 1100 grams and a spleen practically as big, weighing 1000 grams. The surface of the liver was very coarsely nodular and on cutting through it we found large areas of scar tissue such as we are accustomed to find in the post atrophy type of cirrhosis and do not find in the alcoholic type of atrophic cirrhosis. The findings are almost identical with those of his brother except that they were obviously of a much more chronic type. There was a slight degree of acute necrosis as well. This was localized to small groups of cells and I should be inclined to think was analogous to the central necrosis which one often sees in streptococcus infection. You could not say it was central in this case because he did not have any recognizable lobules, the normal architecture had been completely obliterated by the irregularity of the regeneration. The kidneys were entirely normal and we could find no difference between the two. I think Dr Richardson was justified in being cautious. The low position of the left one appeared to be due to the very large spleen, and the right one may well have gone up a little with the small liver. We did not find the focus of calcification. We did not know about that and did not look for it. I entirely agree with Dr Jones in the interpretation of this patient's history.

DR RICHARDSON I should like to add that, on reviewing this case, I feel that I did not pay enough attention to the sudden onset and to the lack of great enlargement of the liver, both of which are definitely against a diagnosis of biliary cirrhosis.

NEW HAMPSHIRE CANCER CONTROL

The brief description of the New Hampshire State Cancer Commission and of its activities, which appears in this number of *The New England Journal of Medicine*¹ is of interest, not only to those who are directly concerned in the cancer problem, but to the whole medical profession and to the community at large. It is a good example of the advantages which are to be obtained when the medical profession itself develops a well studied plan for public health activity designed to supply needed medical service to the community. It is clear that the New Hampshire legislature has not only accepted these plans, but has supported them by appropriations of tax funds sufficient to accomplish the desired results.

In cancer control, as in many other activities of life, the methods which are efficient and practicable in one State may not be immediately adaptable to the needs of another community. Massachusetts, New York, and other States have adopted legislation intended to provide more ef-

ficient service for the indigent and low income cancer patient by very different and indeed much more expensive methods. The New Hampshire plan is worthy of study even on this account alone, and many other States may find it desirable to adopt one or another of the features of the New Hampshire plan when their legislative representatives are aroused to the necessity for providing more efficient service for the cancer patient.

In any case, it is widely recognized that education must play an important part in cancer control over and above the provision of diagnosis and treatment service. Doctor Wilkins' statement makes it clear that the New Hampshire State Cancer Commission recognizes its educational responsibilities, both as regards the public and the medical profession. A brief medical handbook designed to remind physicians of the important aspects of the common forms of cancer and of recent advances in this subject is reprinted herewith and the record of radio talks and newspaper releases sponsored by the Commission in the past year is to be commended.

PROGRESS AT MCGILL UNIVERSITY

THE recent statement concerning the proposed reorganization of the medical school of McGill University¹ raises many interesting questions for discussion. What may be considered the starting point for the change is the recognition of the wisdom of requiring one year of internship before the candidate is qualified to sit for the examination of a licensing board. The internship is required (the statement says) in twenty-eight provinces and states before license, and by the change McGill formally enters the growing group of schools who not only recognize the importance of the internship but insist that it shall become an essentially educational procedure, under the control and direction of some approved medical school. While alternatives are offered, it is expected "that in the majority of cases the postgraduate interne will be chosen as it is the most direct and economical pathway to practice."

The medical course is already long and arduous and it would seem that the addition of a year's internship would prove a serious burden but the fact of the situation is that without the insistence of boards of licensure or of schools of medicine a very high percentage of recent graduates have voluntarily spent a year or more in hospitals. The requirement of the internship by the school is then not an additional burden for most students, but the participation of the school in its control is certain to have a far reaching effect in increasing the value of the experience.

Since ordinarily the internship whether voluntary or compulsory, does take a year in

addition to the medical course, McGill has telescoped, as it were, the five years of seven and one-half months each into four years of nine months each. This raises the old question of how long the academic year should be. Why six months or eight months or ten months? Is there not a great waste of time by the long vacations? It would be helpful if there were a study of the physiological and psychological reasons for the length of the medical course and for the distribution of time. The four quarter year looks like a great saving of time, but the intervals between quarters are in the case of most students too short for the needed recreation after intense application. Perhaps the physiology and psychology of study are too little understood and such long periods of "rest" would not be needed if work were done more in accordance with scientific methods.

There has long been a tendency on the part of medical students to spend much of the summer vacation in laboratory or hospital, for as a class they are eager to learn and do not spare effort to advance in their chosen field. Much is to be said in favor of letting them have free choice in spending their time outside of the formal periods of instruction, but if by so simple a rearrangement as McGill has made, a year's time can be saved in the medical course, the change is worth considering. If the medical course can be extended to nine months why not to ten? Then it would have almost the same content as at present and, including the internship, cover only four instead of five years. If the academic course were extended two months beyond the three years of ten months each, the full medical course would be of exactly the same content as at present but would be ten months shorter.

It may be that the physiological and psychological optimum is an eight months' academic year, but perhaps it is nine or ten. There is no scientific basis for the present scheme, however convenient it may be for some persons, and the experiment at McGill will be watched with great interest. It is a much needed step in the right direction.

THE MEETING OF THE AMERICAN UROLOGICAL ASSOCIATION

Boston has been selected as the place for the thirty-third Annual Meeting of the American Urological Association, at the Hotel Statler, May 19-21, in response to the invitation of the New England Branch of the organization.

This is the largest and most active organized body of urologists in the world, with a membership of 966 active practitioners of this specialty, twenty honorary members, sixty Fellows, ten

associate members and one corresponding member.

The geographical membership list includes 383 in the North Atlantic Section, 103 in the South Atlantic Section, 287 in the North Central Section, 82 in the South Central Section and 136 in the Western Section.

That Dr. George G. Smith of Boston is President of the Association is of particular interest to New England. The Committee of Arrangements, consisting of Drs. F. H. Colby, W. C. Quimby, J. D. Baimey, R. F. O'Neil, J. H. Cunningham, A. Riley, A. H. Crosbie and C. L. Deming, has been diligently at work arranging the details of the convocation.

The subcommittees are as follows: Entertainment, Drs. R. F. O'Neil, R. Chute, H. H. Howard, C. J. E. Kickham; Ladies' Entertainment, Dr. R. Chute; Registration, Drs. G. C. Prather, B. E. Greenberg, E. L. Merritt, E. P. Stone; Golf, Drs. W. H. McNeil, Jr., E. G. Ciabtree, C. S. Swan, E. J. O'Brien; Commercial Exhibits, Dis. C. J. E. Kickham, J. B. Hicks, P. N. Papas; Scientific Exhibits, Drs. R. S. Ferguson, E. R. Mintz, H. H. Ciabtree; Transportation, Drs. S. N. Vose, M. J. Hahn, Jr., B. D. Wetherell; Publicity, Dis. R. C. Graves, A. H. Crosbie, S. B. Kelley; Scientific Meetings, Drs. H. A. Chamberlain, S. B. Kelley, J. B. Hicks.

Unusual plans are under way for the entertainment of the wives and families of the members, with tours to the important historical and other attractive localities in and about Boston.

For those interested in golf, there will be a Tournament at the Woodland Country Club, Monday, May 18, preceding the Scientific Sessions, with a dinner and entertainment in the evening. Teas, luncheons and a Pop Concert by the Boston Symphony Orchestra will complete the social features. The ladies are invited to attend the annual banquet on the evening of May 20.

The American Urological Association was founded on February 22, 1902 at a meeting of the New York Genito-Urinary Society held at the residence of Dr. Ramon Gutierrez, and Dr. Gutierrez was elected the first President of the American Urological Association. The other officers elected as entered in the records of this first meeting are Dr. William K. Otis, Vice President, Dr. John Vanderpoel, Treasurer, Dr. Ferd. C. Valentine, Secretary, and Dr. A. D. Mabie, Assistant Secretary.

The American Urological Association has active members residing in forty-four States of the Union and residents in Canada, Cuba, France, Hawaii, Porto Rico, and South America. There are honorary members in England, New Zealand, Germany, Italy, Holland, Belgium, Austria, France, Switzerland and Scotland.

pitocin, which does not contain the blood pressure raising substance that is present in the whole extract of the posterior pituitary. In addition, the usual measures for combating pre-eclampsia should be instituted as described in a previous paper. Preparations should always be made for one or more transfusions, since these patients are frequently in considerable shock and are apt to bleed severely postpartum. If this procedure fails adequately to control the bleeding or labor does not progress so as to permit delivery within twelve or twenty-four hours, cesarean section may then be the only resort. Rarely severe and uncontrollable postpartum bleeding will necessitate hysterectomy.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning May 17

Berkshire

Thursday, May 21, at 4 30 P M, at the House of Mercy Hospital, Pittsfield Subject Pediatrics (Medical) — The Neonatal State Instructor J L Morse Melvin H Walker, Jr, Chairman

Bristol North

Wednesday, May 20, at 7 30 P M, at the Morton Hospital Taunton Subject Ophthalmology and Otolaryngology (a) The Major Hazards in Diagnosis of Diseases of the Eye, Ear, Nose and Throat as Seen in General Practice (b) Special Treatment in Acute Medical and Traumatic Diseases of the Eye Emergencies Arising in the Treatment of the Ear, Nose and Throat. as a result of certain surveys made by certain Foundations, sociological and pseudosociological groups and certain political groups the idea has been fostered and has grown that a considerable proportion of the population suffers habitually from improper or inadequate, medical care

"However these surveys do not in any instance tell us what medical care this part of our population lacks. They do not tell us whether many or any of these people seek medical care and cannot get it. It is probably true that there are isolated sections where people find it difficult, or even impossible, to get medical attention. It is certainly not true that this applies to even a moderate percentage of the population of the United States

"It has been shown that State Medicine in other countries has not decreased the incidence of contagious disease has not improved the health of the people and has not decreased the amount of loss of time due to illness as well as has been done in the United States without State Medicine

"In England the per capita daily loss of time due to illness has increased 38 per cent. In Germany it has more than doubled. In the United States it has remained stationary for a decade. State Medicine in European countries has never been brought about in response to any demand by the medical profession or any demand by the people who supposedly lack medical care. State Medicine has always been proposed by and passed by the leaders of some political group to serve some political purpose."

In conclusion Dr Johnson stated that, "Until such time as the work of this committee shall be completed and their report and recommendations shall have been received it would be distinctly unwise for the State of Maine to pass any legislation along these lines or to accept any legislation or any proposal along this line from the Federal Government."

The preliminary announcement of the Annual Meeting of the Maine Medical Association shows that it will be held at Rangeley Lakes June 21, 22, and 23. The first meeting of the House of Delegates will be held the evening of the twenty first.

The morning of the twenty-second will be devoted to sectional conferences and the afternoon to scientific papers.

The afternoon session on the twenty third will be devoted to a symposium on Cancer sponsored by the Cancer Committee of the Maine Medical Association.

The following papers will be presented: "Introduction Cancer in Maine" by Dr J W Scannell, Chairman of Maine Medical Cancer Committee.

"Tumors Defined and Classified" by Dr J Gottlieb Pathologist, Central Maine General Hospital.

"Carcinoma of the Breast Its Early Diagnosis Prognosis and Treatment," by Dr C M Robinson Portland.

Carcinoma of the Pelvis Routine Examination Symptoms, Diagnosis and Treatment, by Dr M Rildon Bangor

Carcinoma of the Gastro-Intestinal Tract Its Early Symptoms Diagnosis and Treatment, by Dr E H Risley Waterville

Pathology of Carcinoma of the Breast Pelvis and Gastro-Intestinal Tract, by Dr A. H Morrill, Director Diagnostic Laboratory Augusta

"X Rays in Diagnosis of Malignant Tumors" by Dr Forrest B Ames Bangor

"Radium in the Treatment of Carcinoma," by Dr William Holt, Portland

"X Ray Therapy in the Treatment of Malignancy" by Dr S A Wilson Lewiston.

Discussion of the Cancer Symposium by Dr Elliott C Cotler and Dr Soma Weiss of Boston

There will be one speaker at the annual banquet on the night of June 23

Dr Frederick Thayer Hill of Waterville is the President Elect for the coming year

E H RISLEY MD

BOSTON'S MENINGITIS MORTALITY

With the recent report of two more deaths from cerebrospinal meningitis in Boston, the total number is now forty since the first of the year

SOCIAL SECURITY BOARD GRANTS \$1,323,021 TO THREE NEW ENGLAND STATES

The Social Security Board announced May 8 1936 that U S Treasury checks totalling \$1,323,021.92 have been sent to three New England States with approved public-assistance plans. These checks represent the Federal share of the States expenditures for assistance to their needy aged during the three months ending June 30 1936

The New England States receiving checks the amounts granted, and the estimated number of persons to be aided under the plan according to data submitted by the States are shown in the following table

State	For Assistance to the Aged	
	Amount of check	Estimated number of persons to be aided
Massachusetts	\$1,026,711.92	27,974
Connecticut	221,812.50	8,000
Vermont	74,497.50	4,309
Total	\$1,323,021.92	40,284

LORD HORDER SAID

RECENT DEATH

LULL—HENRY CUSHMAN LULL, M D, formerly of Boston died at his home on Brook Street, Kingston, Massachusetts, May 3, 1936 Dr Lull was a native of Kingston, Massachusetts, the son of George W and Helen Cushman Lull, and a direct descendant of Thomas Cushman one of the Mayflower group who settled in Plymouth

He practiced in Boston for many years and had an office on Tremont Street Dr Lull was eighty seven years of age at the time of his death and left no surviving relatives

OBITUARY

FREDERICK DANFORTH McALLISTER M D

Frederick Danforth McAllister, M D, was born in Lawrence, the son of John G McAllister, M D a Lawrence physician, on October 2, 1872, and died at the Lawrence General Hospital on March 17, 1936, twelve hours following an operation for an acute gangrenous gall-bladder

He was graduated from the Lawrence High School in 1890, Amherst College in 1894, and Harvard Medical School in 1898 His internship was at the Worcester City Hospital, where he worked with a staff of eminent physicians to whom he looked back with much pleasure, and whose influence undoubtedly was of great aid in his later professional life

On December 29, 1899, he was elected a candidate for house physician for six months beginning January 1, 1900, at the Lawrence General Hospital, then located on Methuen Street

On May 28, 1900, he was elected to membership on the Medical Staff of the Lawrence General Hospital

At the opening of the present Lawrence General Hospital in 1903, on the Russell Estate, he began to carry a three months' surgical ward service, and performed this annual duty up to the time of his death

Dr McAllister was noted for his good judgment and sound knowledge of diagnosis and treatment, including operative procedure He was another of those physicians, on the Medical Staff of the Lawrence General Hospital, of whom it could be said always that the patient's interests were perfectly safe in his hands

Dr McAllister was Secretary of the Medical Staff from 1923 until he died

His life was upright as should become a professional man, and the Medical Staff of this Hospital hereby expresses a feeling of loss at his untimely death

He was a member of the Lawrence Medical Club, a Fellow of the Massachusetts Medical Society, American Medical Association and American College of Surgeons

His immediate surviving relatives are his widow, a daughter, a brother and two sisters

Your committee closes this memorial with a quotation furnished by his brother, Rev Frank B McAllister, and attributed to John Brierley

"May we not say of death itself that it is the final and effective remedy? On the physical side it is kindly Nature's way out of an impossible situation It is heroic surgery When the forces of disease have prevailed against her ordinary methods of healing, she dissolves in this way a combination that has become simply painful Nothing has been destroyed What has happened is that the arrangement of particles round a hopelessly weakened center has to come to an end, leaving these particles free, for a new and sounder grouping"

REMOVAL

LOUISE PAINE TINGLEY M D, announces the removal of her office to 416 Marlborough Street Boston, Telephone Kenmore 0822

MASSACHUSETTS INSTITUTE OF TECHNOLOGY, DEPARTMENT OF BIOLOGY AND PUBLIC HEALTH

ANNOUNCEMENT OF A SPECIAL PUBLIC HEALTH COURSE

A special course of training will be offered this year from June 4 to July 3, inclusive for men and women interested in public health work The course will be given as part of the training now being offered to students in residence at M I T under the Federal Social Security Act.

Instruction will be given in the following subjects: Public Health Administration, Epidemiology, Vital Statistics, Communicable Diseases and Public Health Problems

The work in Public Health Administration will include the organization and activities of municipal, county, state and federal health agencies, public health surveys, organization of public health campaigns, and the use of the city and rural health appraisal forms

The course in Communicable Diseases will consider the biology of disease and the theories of immunity Special instruction will also be given in the organization and conduct of the community program against tuberculosis

In Epidemiology the sources of infection, modes of

spread of disease the methods employed in studying and controlling epidemic diseases and the lessons to be learned from analyses of specific epidemics will be considered.

Vital statistics will consider the sources of statistical information, methods of collection computation of rates, tabulation graphical presentation analyses and interpretation.

Under Public Health Problems special assignments will be made for study analyses and group consideration. Current public health problems discussed in the professional journals and daily press will also be presented and discussed.

Classes will be held daily from 9 A. M. to 12:00 P. M. and 2 to 3 P. M. exclusive of Saturdays and Sundays.

The registration fee is \$5.00 Tuition fee \$70.00 (Total \$75.00).

Inquiries should be addressed to the Department of Biology and Public Health Massachusetts Institute of Technology Cambridge Mass. Registration material will be sent on request.

UNITED STATES CIVIL SERVICE EXAMINATIONS

Medical Officer (Specialist in Venereal Disease Control)

Medical Officer (Specialist in Cardiovascular Renal Disease)

\$3,800 a Year

Applications must be on file with the United States Civil Service Commission at Washington D. C., not later than May 25 1936.

The United States Civil Service Commission announces open competitive examinations for the positions named above. Vacancies in these positions in the field and in positions requiring similar qualifications will be filled from these examinations, unless it is found in the interest of the service to fill any vacancy by reinstatement transfer or promotion.

REPORTS AND NOTICES OF MEETINGS

SOUTHEASTERN MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH

The spring meeting of the Southeastern Massachusetts Association of Boards of Health was held in Hyannis on Wednesday April 22 with some thirty members present representing fifteen towns in the district. The principal speaker was Dr. Gaylord W. Anderson of the State Department of Public Health and his subject Milk Borne Epidemics.

Dr. Anderson addressed his remarks directly to the health officer outlining the principles of prevention and emphasizing the necessity of the pasteurization of milk using through his paper the simile of the steamship without the customary safety precautions life boats life preservers special details of construction etc. It might make its voyages for a while without accident but should one occur there

would be criticism and the question would be asked "Why was not this prevented?"

It is true that milk borne epidemics are not common in fact they might be termed rather rare but when they do occur they attract widespread attention and there is regret that means of prevention have not been taken. In communicable diseases as in the case of the steamship we should profit by the unfortunate experience and take precautions against future repetition of the disaster. It is one of the duties of a board of health to protect the public, and to effect this it should become better acquainted with the causes of diseases.

There are three general classes into which milk borne diseases may be divided based on the mode of transmission. First there are diseases of the cow e.g., tuberculosis and here the speaker complimented the Cape for its pioneer work in the prevention of tuberculosis in its cows. Secondly the cow may be infected from man and thirdly there are cases in which the cow is not involved the infection coming from men directly or through unsanitary conditions in the handling of the milk.

The principal diseases of the cow which may be communicated through milk are tuberculosis and undulant fever. The former through the elimination of infected cattle has almost reached the vanishing point in localities in which only tuberculosis tested cows are permitted. Cape Cod as has already been noted is a leader in requiring this precaution. Undulant fever is not at all common but is likely to attract much more attention when more generally recognized. It is now widespread, but is not diagnosed in the majority of cases. It could be controlled by cutting off the supply of milk from "diseased" cows but there are several obstacles. If carried out to the letter it would be likely to cause a shortage of milk. The testing of the cows to determine whether they are infected would be exceedingly difficult. Even if the cow is infected, its milk may not contain the specific germ. If it does this may prove to be an intermittent rather than a constant condition. Then again just what the effect on man may be is not certain. Some human beings readily contract the disease, but in other cases small doses of infected matter seem to result in immunization. These facts suggest some of the difficulties in any program of prevention due to the cow.

Forty-two cases of undulant fever were reported last year in the state, but this is by no means the full number for physicians are not yet at all familiar with it while in its milder forms it is likely to attract little attention. Comparatively few of the cases are fatal but debilitating effects of the disease may last for a long time. Medical authorities are now busily at work trying to solve some of these problems. Meanwhile pasteurization of milk furnishes an important step toward reasonable safety.

In the second group cows become infected with some diseases through contact with man septic sore throat scarlet fever and diphtheria among them. Milk which is such a good food for man and ani

mals, is equally noulshing to many of the lower organisms and disease germs multiply rapldly in it. Communities using a milk infected with septic sore throat for example, develop many cases, and there have been some startlling outbreaks. A number of local ones were noted by Dr Anderson, one of which was in a town of 4,000 which developed 900 cases with 48 deaths. In another instance, 25 persons used the milk from an infected cow. Of these, 18 became sick and two died, while members of the group carried the infection to two other towns, one of them forty miles distant from the place of original infection.

"Now what are the chances of prevention here?" queried the speaker. To take cultures of the milkers and handlers, is not practicable, and might after all tell only part of the story. Bacterial analysis of the milk would not reveal the presence of the germ early enough to prevent infection, while examination by a veterinarian, although good in principle is too cumbersome, since a daily examination may be necessary. There is only one way to be sure in cases like these, namely, to pasteurize the milk.

What is true of septic sore throat applies practically to scarlet fever, and this demands the same measure of general protection, pasteurization. So far as Massachusetts is concerned milk borne diphtheria is rare with no cases in the past ten years, but it is more of a problem in some other places.

In the third group are maladies, communicated to the milk by human beings, among which are typhoid and dysentery, with some septic sore throat and scarlet fever. There are occasional outbreaks of typhoid due to the use of raw milk, the presence of a carrier or some unsanitary procedure, such as neglect in the disposal of sewage, failure to protect the water supply used for washing utensils or carelessness on the part of individuals.

Theoretically, the ordinary measures of prevention should care for these troubles, but there are a number of practical difficulties. A person may be affected mildly by typhoid, or may just be coming down, or indeed be a carrier, without being aware that he has had the disease. Cultures are very variable and in fact are not always reliable. Back of all this as a method of prevention is the health education of the people, whereby the food handler may eliminate all risks from personal carelessness or from unsanitary conditions. With milk it is absolutely necessary to have clean cows, clean milkers, and clean handling into clean bottles. And then, as a superimposed protection, pasteurization. This is not, as it is sometimes improperly characterized, the cleaning up of dirty milk, but the safeguarding of milk against possible infection through factors not always otherwise to be controlled. It is not a substitution for sanitation, but is a reasonable means of prevention of various communicable diseases that are due to the use of raw or contaminated milk. "Make sure by pasteurization," said Dr Anderson in conclusion.

The round table discussion by the health officers, which usually closes these meetings, was based at this session on a question by the secretary, Mr

George F Crocker, Jr, who is district milk inspector. It concerned the attitude which the health board should take toward a new milk distributor, who seeks to establish himself in a place already well supplied with milk. After considerable discussion it was the consensus that, if the requirements with which the law surrounds such an application are completely fulfilled, and they should be for every town interested, the board of health has no option if the milk comes up to the standard. It is then purely a commercial question, and should be considered by the local chamber of commerce or official business organization.

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at 4 30 P M, May 25, 1936, in the Amphitheatre of the Children's Hospital, Boston, Mass. Program 1. An Identical Twin Presenting a Bicuspid Pulmonic Valve. Dr Harry Dietrick. 2. Two Cases of Idiopathic Hypertrophy of the Heart with Recovery. Dr Mark I Makler. 3. Arachnodactylia. Dr Hyman Green. 4. A Case for Diagnosis. Dr Henry F Keever. 5. Behavior Difficulties in Children Who Have Attended Heart Clinics. Dr Bronson Crothers. 6. Some Cases of Transposition of the Great Vessels. Dr Paul W Emerson. 7. A Definite Clinical Syndrome Associated with Enlargement of the Heart in Infants and Young Children. Dr M A Kugel (Mt Sinai Hospital, New York).

All members of the New England Heart Association and interested physicians are cordially invited to attend.

JAMES M FAULKNER, M D, *Secretary*

AMERICAN UROLOGICAL ASSOCIATION

PROGRAM

TUESDAY, MAY 19, 1936—9 00 A M 12 30 P M

Surgical Procedures in Neurodynamic Pathology of the Upper Urinary Tract. William P Herbst, Washington, D C.

The Present Status of Renal Sympathectomy. Thomas E Gibson, San Francisco, California.
Discussion. Lawrence R Wharton, Baltimore, Maryland.

Hypernephroma. Lawrence T Price, Richmond, Virginia.

Irradiation and Malignant Renal Disease, Effect of Irradiation on the Acquired Single Kidney. Arbor D Mungei, Lincoln, Nebraska.

Hemorrhagic Cyst of the Kidney. J Dellinger Barney, Boston, Massachusetts.

Discussion. Archle L Dean, Jr, New York City.

An Experimental Study of Injuries of the Upper Urinary Tract. W Calhoun Stirling and A Lands (by invitation), Washington, D C.

Diagnosis and Treatment of Trauma of the Kidney. Austin H Wood, Baltimore, Maryland.

Discussion Nathaniel P Rathbun Brooklyn New York
Miley B Wesson San Francisco California.

Renal Atrophy Robert E Cumming Detroit, Michigan.

The Atrophic or Hypoplastic Kidney F G Harrison, Philadelphia, Pennsylvania.

Discussion William F Braach Rochester Minnesota
Elmer Hess Erie Pennsylvania

THURSDAY MAY 19 1936—2 00 P.M. 5 30 P.M.

The "Cord Bladder" Definition Treatment and Prognosis When Associated with Spinal Cord Injury Donald Munro Visiting Surgeon for Neurosurgery the Boston City Hospital, Boston Massachusetts. (By invitation)

The Diabetic (Cord) Bladder Richard D Gill Wheeling West Virginia.

The Technic of Suprapubic Cystotomy for Drainage Montague L Boyd Atlanta, Georgia

Discussion Paul A Ferrier Pasadena California
Irving Simons New York City

The Ureteral and Renal Complications of Carcinoma of the Cervix Roger C Graves Charles J E. Kichham and Ira T Nathanson (by invitation) Boston Massachusetts

Vascular Obstruction of the Ureter in Children Meredith F Campbell New York City

Supernumerary Ureters with Extravesical Openings Henry Dawson Furniss New York City

Discussion Roy B Henline New York City
Fletcher H Colby Boston, Massachusetts

Demonstrations

A New Cystometer Devised to Minimize the Present Difficulties David W MacKenzie and Sidney Beck (by invitation) Montreal Canada

An Improved Filiform Guide Floyd C Hendrickson Canton Ohio

Transurethral Prostatotomy for Relief of Prostatic Abscesses and Acute Obstructive Prostatitis with an Electro-Prostate Gideon Timberlake, St. Petersburg Florida.

WEDNESDAY MAY 20 1936—9 00 A.M. 12 30 P.M.

The Relationship Between the Chemical Composition of Renal Calculi and Associated Bacteria James T Priestley Rochester Minnesota.

A Study of Recurrence Following Operations for Nephrolithiasis Francis Patton Twinem New York City

Factors Determining the Management of Ureteral Stones an Improved Method of Their Cystoscopic Removal. Thomas D Moore Memphis Tennessee

Discussion Fuller Albright Boston Massachusetts
Linwood Keyser Roanoke Virginia.

Cystitis Emphysematosa N L Burrell Springfield Ohio

The Treatment of Incrusting Alkaline Cystitis Alexander Randall and Edward W Campbell Philadelphia, Pennsylvania.

Discussion William E Stevens San Francisco California

Further Developments in the Surgery of the Prostate Joseph F McCarthy New York City

Mortality in Prostatic Surgery Harry C Roelich and Lester A. Riskind (by invitation) Chicago Illinois

Discussion Gilbert J Thomas Minneapolis Minnesota
I G Duncan Memphis Tennessee
Nathaniel G Alcock Iowa City Iowa

The Founding of the American Urological Association with Tribute to Its Founder Colin Luke Bett New York City

WEDNESDAY MAY 20 1936—2 00 P.M. 5 30 P.M.

President's Address

Dr George Gilbert Smith Boston Massachusetts

The Ramon Goltaras Lecture The Influence of Infection of the Lower Urinary Tract and Reproductive Organs on the Kidneys with Special Reference to Lithiasis and Hydronephrosis Mr H P Winsbury White London England

Discussants Hugh Hampton Young Baltimore Maryland Hugh Cahot Rochester Minnesota
J Dellinger Barney Boston Massachusetts
Henry G Bugbee New York City William E. Lower Cleveland Ohio

Business Meeting. (To follow)

Banquet 8 00 P.M.

THURSDAY MAY 21 1936—9 00 A.M. 12 30 P.M.

Cocaine Absorption in the Urethra and Bladder a Report on Quantitative Determinations. Ernest Rupel and R. N Harger (by invitation) Indianapolis Indiana.

Incontinence in the Male and Female with a New Operation for Its Relief. Oswald Swinney Lowsley New York City

A Histo-Pathological Study of the Female Bladder Neck and Urethra David W MacKenzie and Sidney Beck (by invitation) Montreal, Canada

Discussion Alfred I. Folsom, Dallas Texas
Thomas J Kirwin New York City

X Ray Therapy in the Treatment of Bladder Tumors. Albert E Bothe Philadelphia, Pennsylvania

Infiltrating Carcinoma of the Bladder J A Campbell Coleton and W F Leadbetter (by invitation) Baltimore, Maryland

The Grading of Bladder Tumors Major Raymond O Dart, Army Medical Museum Washington D C (By invitation)

Five-Year End Results in the Bladder Tumor Registry Russell S Ferguson New York City Chairman of the Carcinoma Registry Committee of the American Urological Association

- Discussion Benjamin S Baringer, New York City
- Enterovesical Fistula Charles C Higgins Cleveland, Ohio
- Primary Carcinoma of the Seminal Vesicle Andrew McNally and Frank M Cochems (by invitation), Chicago, Illinois
- Discussion James F Balch, Indianapolis, Indiana
- THURSDAY, MAY 21, 1936—2 00 P.M 5 30 P.M
- Heminephrectomy Its indications and Limitations Elmer Hess, Erie, Pennsylvania
- Resections of the Kidney Benjamin S Abeshouse and Albert E Goldstein, Baltimore, Maryland
- Unsuccessful Plastic Operations for Hydronephrosis John K Ormond, Detroit, Michigan
- A Simple Method for Doing Nephropexy Charles M McKenna, Chicago, Illinois
- Discussion William C Quinby, Boston Massachusetts Edwin Bee, New York City

- How Prevalent Are Smegma Bacilli? Their Alleged Importance as a Confusing Factor in the Examination of Urine for Tubercle Bacilli by the Centrifugal and Smear Methods Howard S Jeck and Charlotte Hanley (by invitation) New York City
- Impotence and Masturbation from the Urological Point of View Max Huhner, New York City
- The Surgery of Genital Elephantiasis (nontropical) Ernest M Watson, Buffalo, New York
- Discussion Winfield W Scott, Rochester New York, David M Davis, Philadelphia, Pennsylvania

NEW ENGLAND PHYSICAL THERAPY SOCIETY

ANNUAL MEETING

The Annual Meeting of the New England Physical Therapy Society will be held at the Hotel Kenmore, Boston, on Wednesday evening, May 20, 1936, at 8 o'clock

PROGRAM

Business Meeting

- Reports of Officers
- Reports of Committees
- Election of Officers

Scientific Program

Injection Treatment of Varicose Veins, Technique and Results (Motion pictures will be shown) DeWitt G Wilcox, M.D., Professor Emeritus of Gynaecology, Boston University Medical School

Discussion Herbert G Dunphy, M.D., Member Surgical Staff, Boston City Hospital and Newton Hospital

Question Period

The Council will meet promptly at six o'clock
Informal Round Table Dinner at six thirty o'clock
As this is the last program to be given by the So-

ciety until October it is hoped that all members will make a special effort to be present

Members of the medical profession are cordially invited to attend

WILLIAM D McFEE, M.D., *Secretary*
Boston, Massachusetts

TRUDEAU SOCIETY

A meeting of the Trudeau Society will be held on Thursday, May 21, at 4 P.M., at the North Reading State Sanatorium, North Wilmington, Mass. Dr. David Zacks of the Chadwick Clinics will speak on Asymptomatic Tuberculosis. Drs. Earle C. Wiloughby, Rufus R. Little and Anna H. Maxwell will discuss Treatment of Tuberculosis by Means of Collapse Therapy in Children under Seventeen Years of Age. Dinner will be served at 6 30 P.M.

MOSES J. STONE, M.D., *Secretary*

THE NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The eighth spring meeting of the New England Obstetrical and Gynecological Society is to be held on Thursday, May 28, 1936, at Providence, R.I. The following program has been arranged

Following the morning and afternoon hospital activities, the Society dinner will be held at the Squantum Club

MORNING PROGRAM

Registration at Rhode Island Medical Society Library, 106 Francis Street

Providence Lying-In Hospital

9 10—Inspection of hospital

10 10 30—Management of 100 cases of Placenta Praevia at the Providence Lying In Hospital Dr. John G. Walsh

10 30 11—Treatment of Heart Disease complicating Pregnancy and Labor in 609 cases at the Providence Lying In Hospital Dr. Frank T. Fulton

11 15 11 45—Treatment of Premature Infants with demonstration of an inexpensive oxygen box. Drs. Buffum and Lord

11 45 12 15—Deduction to be drawn from 108 Maternal Deaths at the Providence Lying In Hospital Dr. E. S. Brackett

1 00 — Luncheon. Guests of Providence Lying In Hospital

Rhode Island Hospital

9 11—Operating clinic. Drs. Sweeney, Buxton and Gynecological Staff. There will also be available for those who wish to see them, other operations by the general surgical service

11 00—Dry clinic in the Peters House Auditorium, Rhode Island Hospital

11 11 30—Presacral nerve resection. Report of cases with lantern slides. Dr. George W. Waterman

11 30 12 15 — Panhysterectomy vs. supracervical hysterectomy with report of a series of cases. Dr. Thomas W. Grzebień

Discussion by Drs. Waterman and Clarke

- 12 151st 45—Gonorrrhea in the Female Dr John F Murphy
12 45 — Luncheon as guests of the Rhode Island Hospital

SOCIETY MEETINGS CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK
BEGINNING MONDAY MAY 18 1936

Monday May 18—

- 10 A.M. P.M. 30 P.M. The American Urological Society Hotel Statler
4 P.M. Surgical Lecture at the Peter Bent Brigham Hospital Amphitheatre by Dr K. H. Glantz

Tuesday May 19—

- American Urological Association Hotel Statler
10 A.M. Boston Dispensary 5 Bennet Street
Boston. Clinical Diagnosis of Jaundice Dr Howard M. Cline
9:30 A.M. Massachusetts General Hospital Thoracic Clinic. Ether Dome
11:30 A.M. Massachusetts General Hospital Nerve Eye Conference Gut Patient Department
1 P.M. South End Medical Club 654 Commercial Avenue Boston
10 P.M. Pediatric Ward Visit Massachusetts General Hospital and Ear Infirmary

Wednesday May 20—

- American Urological Association Hotel Statler
8 A.M. Massachusetts General Hospital Grand Rounds. Orthopedic Department
9:30 A.M. Boston Dispensary 5 Bennet Street Boston Hospital Case Presentation Dr S. J. Thannhauser
11:30 A.M. Clinical Pathological Conference Children's Hospital
1 P.M. Surgical Lecture at the Peter Bent Brigham Hospital Amphitheatre by Dr K. H. Glantz

Thursday May 21—

- American Urological Association Hotel Statler
8 A.M. Massachusetts General Hospital Circulatory Clinic Ward F
9:30-9:50 A.M. Clinic, Surgical and Orthopedic Staffs of the Children's Hospital at the Children's Hospital
9:30 A.M. Boston Dispensary 5 Bennet Street Boston. Social Service Case Presentation Miss Edith Canterbury
9:15 A.M. Massachusetts General Hospital Neurological Conference Ether Dome
12 M. Massachusetts General Hospital Clinical Pathological Conference

Friday May 22—

- 9:30 A.M. Boston Dispensary 5 Bennet Street, Boston Newer Aspects of Diabetes Dr Reginald Fitz.
1 P.M. Massachusetts General Hospital Clinical Meeting of Staff of the Children's Medical Service Ether Dome
12 M. Massachusetts General Hospital Urological Conference Out Patient Department

Saturday May 23—

- 9:30 A.M. Boston Dispensary 5 Bennet Street Boston Hospital Case Presentation Dr S. J. Thannhauser
10 A.M. 1 P.M. Staff Rounds at the Peter Bent Brigham Hospital. Conducted by Dr Henry A. Christian.

Open to the medical profession

BOOK REVIEWS

National Medical Monographs. Diseases of the Chest J. Arthur Myers 285 pp. New York National Medical Book Company Inc.

The author of this book has been connected with the Lymanhurst School in Minneapolis for the past fourteen years. He has had an opportunity there to study the problem of childhood tuberculosis in 12,000 children. This work has given him a wide reputation and in 1934 the National Tuberculosis Association presented him with its Trudeau Medal. Therefore anything that Dr. Myers writes on the subject of tuberculosis has the stamp of authority.

The present volume consists of 360 small pages, 200 of which are devoted to tuberculosis. The author writes in outline form with summaries at the end of each chapter. He makes his points with unusual clearness. Any student of the tuberculosis problem who has not read Dr. Myers' previous works should hasten to read this latest summary of his views in former publications particularly to his books entitled "Tuberculosis Among Children" and "The Child and the Tuberculosis Problem." The author has covered much of the same ground. The present volume deals with adult as well as childhood tuberculosis and takes up artificial pneumothorax treatment in addition to other phases of the general problem. It also shows certain changes to the author's view point.

In the opinion of the reviewer this discussion of tuberculosis represents the author's best work and

is in every way a masterly production. This does not mean that everyone will agree with his opinions, and probably the majority of critics will feel that he has failed as yet to prove his favorite thesis—that a first infection with tubercle bacilli sensitizes an individual toward later reinfection without producing an appreciable immunity. However, most readers will agree with Myers that infection with tubercle bacilli should be avoided at all ages. Again, all will not agree that this necessarily means handling cases of tuberculosis in the hospitals as if they were cases of acute contagious disease. There will be debate also as to the degree of risk assumed by doctor and nurse in caring for the patient ill with tuberculosis.

The second part of the book attempts to cover, in 160 small pages the problems of "Pneumonia, Suppurative Conditions of the Bronchi, Lungs, and Pleurae, Tumors within the Thorax, Massive Collapse, Foreign Bodies, Spontaneous Pneumothorax, and Pulmonary Embolism, Diseases Due to Other Mould-like Bacteria, True Moulds, and Yeast-like Fungi, and Diseases and Conditions Caused by Inhalation of Dust." The author gives a good summary of the high spots of present opinion on these problems but so short a discussion is of little value to either student or practitioner. The book hardly deserves the title, "Diseases of the Chest."

Individual Exercises. Selected exercises for individual conditions. George T. Stafford, Harry B. DeCook, and Joseph L. Picard. 111 pp. New York: A. S. Barnes & Company. \$1.00.

This paper-covered book of some 100 pages is designed chiefly for laymen and women. The Preface urges that before these exercises are taken, the individual should first place himself in the hands of his physician and obtain a correct diagnosis of his condition. Once this is made the authors believe that the individual himself can then select his exercise program from the sets described in the book. There follows Chapter I on "The Need for Exercise in Present-Day Society" and in subsequent chapters there are dissertations on Blood Pressure, Constipation, Digestive Disorders, Foot Disturbances, Heart Disturbances, Hernia, Infantile Paralysis, Kidney Disorders, Knee Disturbances, Malnutrition, Mental Disorders, Posture, Ptosis, Neurasthenia and Scoliosis. With each dissertation sets of progressive exercises are suggested.

The authors have not escaped certain pitfalls which are always met when diseases and lesions are discussed with the laity by other members of the laity. The authors have had much contact with physicians and appear to be men especially well trained for the important positions which they hold. Under infantile paralysis, for example, this difficult subject of muscle training would be better left to physicians to describe. There is definite danger of too much dogmatism in the description of knee disturbances and under posture no special attention is paid to the method of correcting the prevailing faults of body mechanics. Scoliosis is in the review-

er's opinion a disease in which there is much danger for over- as for underexercise. There is the possibility that a well made and fairly rigid curve will increase if the spine is made too flexible. Chapter IV is entitled "Maintaining Health or Keeping Physically Fit" and follows a proposed health scale which provides a check consisting of (A) a personal health index of twenty points and (B) health habits of twenty points, with the opportunity for a check six months after the exercises are started. The author has a bad idea but probably hardly allows for the limitations of human nature.

Chapter V, which comprises a little more than the book, is made up of 100 exercises with illustrations and fairly easily grasped in brief.

The advice is constantly given that the individual should consult their physician for a diagnosis. We believe that the physician himself should prescribe at least the type of exercises and should be the one to watch the effect, not only the corrective effect, but the effect on the patient's general condition.

As a calisthenic manual, this book will be useful for the average man or woman who does not require careful medical supervision.

Radium Treatment of Skin Diseases, New Diseases of the Eyes, and Tonsils. F. Williams. 118 pp. Boston: The Stratford Company. \$2.00.

This little book is a summary of the work of the pioneers in radium therapy. Dr. Williams began experimenting with radium in 1900, after its discovery by Madame Curie. He has separated the beta rays from the gamma rays and found out what screening was necessary. He has found the beta rays and demonstrated that gamma rays passed through the body sufficiently to be detected on a fluorescent screen. His first clinical use was in a case of psoriasis where he found that the gamma rays destroyed the lesions, but the beta rays were necessary.

Over a period of thirty years the writer has been using radium in skin diseases, new growths of the skin, spring catarrh of the conjunctiva, neoplasms of the eyelids, opacities of the cornea, cataracts, enlarged tonsils. The technique used in these conditions is described, together with the results. Sufficient data are not given to show what per cent of the cases treated for a disease showed improvement or were cured.

This book is excellent as a report of what man has been able to do with radium. The methods of treatment of skin cancer and the conditions are not detailed enough to teach another how to use radium. The reviewer does not agree with all the writer's statements or with some of the methods of treatment and wonders if sufficient attention has been given to newer methods which have been developed. He finds it difficult to explain how Dr. Williams can cure cataracts when so many radiologists have found that they are quiescent.

NUMBER 21

CLINICAL CONSIDERATIONS IN REGARD TO ETIOLOGY, CHARACTERISTICS AND PROGNOSIS OF ESSENTIAL HYPERTENSION AT DIFFERENT AGES*

A Review of 224 Cases

BY ROBERT S. PALMER, M.D.,† AND EDWARD G. THORP, M.D.‡

DURING the past five years we have attempted to find early cases of essential hypertension in hospital and private practice and by means of periodic health examinations of supposedly normal people. It is our purpose to compare these early cases with moderately advanced and late cases encountered and followed over the same period of time.

In declaring a case mild, moderate or severe, we have been influenced by the height of the blood pressure, the absence, or presence and amount of organic cardiovascular change and the response to treatment. A blood pressure not over 180 mm. of Hg systolic or 115 diastolic, marked variability, usually with one or more observations of normal blood pressure (not over 140 systolic, 100 diastolic), relative freedom from organic change in the cardiovascular system, indicated a mild or early case. A blood pressure of 180 to 230 systolic, 115 to 130 diastolic, variable and with a fairly favorable response to sedatives and rest, with none to a moderate degree of organic cardiovascular change indicated a moderate case. A very high blood pressure of over 230 systolic and over 130 diastolic, variable, but usually above these figures and as a rule not falling lower than these figures with rest and sedatives and showing marked organic cardiovascular change, indicated a severe case. There were all gradations from mild to severe.

Cases may also be graded according to intensity, acceleration or rapidity of progress from the slow typical benign essential hypertension of middle life and beyond lasting ten or even twenty years to the rapidly fatal so-called malignant hypertension lasting a few weeks to not over two years. The latter occurred in this series only under fifty two years of age more commonly in females. Again we have observed all gradations in intensity.

This series of 224 cases includes none of primary renal disease. There was one case of

coarctation of the aorta, one case of adrenal cortical adenoma, two "cancers" of essential hypertension always to be considered. No cases of paroxysmal hypertension due to pleochromatic medullary tumors have been recognized. There were 118 males 106 females. At earlier ages males predominate since the majority of our early or mild cases were found by periodic health examination of either exclusively male or predominately male groups.

Excluding the patients with coarctation of the aorta and adrenal cortical adenoma, there was one case of a male aged twenty two years, thought to be the mild benign type who died suddenly after swimming, of unknown cause, and a fourth patient, the nature and the severity of whose disease was not certainly determined. The remaining 220 were graded as follows, mild or early 79, moderate 69, and severe 72. Table 1 indicates the percentage incidence of etiological factors.

TABLE 1
ETIOLOGICAL FACTORS (PER CENT)

	Family History of Degenerative Disease	Obesity	Nervous Instability	Endocrine Abnormalities (Female)
Mild	52.1	45.3	68.0	90.9
Moderate	63.3	69.2	86.3	88.3
Severe	70.0	67.7	75.5	96.0

The incidence of a family history of degenerative vascular disease is definitely greater in cases graded moderate or severe. This may be interpreted as representing constitutional susceptibility in current medical terminology and an X or intrinsic factor, more regularly present in the moderate or severe cases. The absence of this factor in almost half of the mild cases suggests that many of them may have been simple vasomotor instability and not true early essential hypertension. To date we do not know of any certain way to distinguish between benign vasomotor instability with elevations of the blood pressure in young male adults except by observation. Observation unless very tactful,

From the Medical Clinic of the Massachusetts General Hospital.
†Palmer, Robert S. — Assistant in Medical, Massachusetts General Hospital.
‡Thorp, Edward G. — Assistant in Medical, Massachusetts General Hospital.
For records and addresses of authors see "This Week's Issue," page 1053.

has the disadvantage of producing in some of these individuals a high blood pressure phobia, in itself disquieting and occasionally, we suspect, being partly responsible for the precipitation of symptomatic essential hypertension in susceptible individuals.

The most constant factor in the etiology of essential hypertension is a familial disposition though it is not clear how strong the family history must be to be significant since as Allan¹ points out, hypertension may be present in as high as 40 per cent of the adult population. The chance is considerable that any individual may have a hypertensive family history. Nevertheless Ayman² has shown that the children of hypertensive parents have a much greater chance of showing elevated blood pressures than the children of nonhypertensive parents. On the whole the best guide to a diagnosis of potential essential hypertension is a strong family history of degenerative vascular disease.

Obesity is likewise more prominent in the moderate and severe groups. Whether obesity is present because the average age of these cases is older, whether obesity is a related cause, or whether finally it is an effect of the disease, is not clear. If one considers essential hypertension as a constitutional irritability or instability of the sympathetic-adrenal system, a chronic emergency as it were, and recalls the stimulating or mobilizing effect of the sympathetic adrenal system on carbohydrate metabolism, particularly when mental or emotional stress without motor discharge is the exciting cause, one can see at least theoretically, how obesity might develop as an effect of, rather than a cause of this disease. Obesity in essential hypertension conceivably may be the result of a functional endocrine disturbance analogous to that of pituitary basophilism.

Undue nervous instability is present in quite a high percentage of all cases, varying from consciousness of uncomfortable inner tension, through a variety of complaints indistinguishable from those of so-called functional nervous diseases without hypertension, including phobias, exaggerated fears, anxiety attacks. A small percentage suffered more or less serious nervous breakdowns. While it is often difficult to judge how much of the functional element is induced by fear of blood pressure, nevertheless, nervous symptoms often precede and lead to the finding of the blood pressure. Occasionally unusual situational difficulties paralleled the onset of the elevated blood pressure. However, nervous tension is very likely at most a precipitating cause since its occurrence is actually greater in a control group of patients without hypertension undergoing hospital study.³

Endocrine abnormalities or dysfunction are the most commonly associated factors in essen-

tial hypertension of females if the menopause is included in this category. Naturally, the menopause is the rule in females over forty-five years with essential hypertension. On the other hand, in the younger group of seven females under thirty-six years of age with severe hypertension only one had had no abnormality of periods or of pregnancy. Two had had abnormal catamenia. Four had suffered from toxemia of pregnancy. Of twelve females aged thirty-six to forty-five with severe hypertension, four had suffered actual or probable toxemia of pregnancy. Two had had abnormal periods, four had experienced an early menopause. Only two showed no obvious abnormality. Abnormalities of catamenia or of pregnancy, and the glandular reorganization at the menopause are significantly associated with essential hypertension in females. Among females, chronic pyelitis may be associated with severe hypertension. This was noted in two of the seven females with severe hypertension under thirty-six years of age.

When this series is arbitrarily divided according to age, some interesting facts are brought out.

There are fifty-seven cases under thirty-six years of age. Most of these (forty-six) are males since many were discovered by periodic health examinations in exclusively male or predominately male groups. The largest proportion of mild cases are in this group (thirty-seven males, two females). They are free from organic change. The blood pressure is variable, often normal, is readily controlled by rest or sedatives. In many of these cases the diagnosis is probably vasomotor instability, not true essential hypertension. Cases of this sort, and at older ages as well, are known to regress spontaneously and fail to recur over many years. Vasomotor instability with frequent observations of elevated blood pressure is common in young male adults. The blood pressure may be as high as 180 systolic, as pointed out above. An uncertain or tentative diagnosis of high blood pressure in some instances, conditions the patient to anxiety in regard to blood pressure and in susceptible persons may be instrumental in precipitating or hastening the onset of the disease. The diagnosis of essential hypertension is made when they do not regress but show definite progress toward higher blood pressures and irreversible organic change. We feel that therapeutic efforts at this point are likely to be most effective. Only two females at this age with mild or questionable hypertension have been observed, both found by periodic health examination. What the incidence of early, variable, mild hypertension or vasomotor instability of this type is among females we do not know, due to the fact that we have not had the opportunity of submitting to periodic health examination a

large enough number of young adult females. Our experience with clinical cases of essential hypertension in young adult females on the other hand, leads us to expect a serious often the malignant form of the disease.

Six cases under thirty six years of age (four male, two female) were graded moderate duration differed from the mild cases in having higher pressures variable and responding favorably to rest and sedatives but failing to return to normal. Organic changes were absent or slight in degree and not asymptomatic.

There were ten cases of severe hypertension (three male and seven female) in this group under thirty six years. The blood pressure had been known to have been present for weeks up to fourteen years, average 3.7 years. Organic cardiovascular change, usually of marked degree, was present in all. Congestive or anginal failure or loss of reserve was present in four hypertensive encephalopathy or cerebral accident occurred in three. Three were untraced. Four died, one of unknown cause, one of cerebral accident, two of uremia. The point of great interest is that seven of ten severe cases were females. Four were designated malignant because of edema of the optic nerves, and the rapid course of the disease, five months to 27 years. Three of these were females.

Of patients aged thirty six to forty five years there were thirty three (eleven males twenty two females). Included in this group was the patient with an adrenal cortical adenoma which was removed without notable effect on the blood pressure. The others were graded eleven mild or early, six moderate fifteen severe.

Of the eleven mild or early cases four were females, seven males. Seven of these were discovered incidental to a periodic health or other routine examination. Of the six graded moderate, five were females. Of the fifteen severe cases, twelve were females. Five had cardiac asthma, congestive or anginal failure, or milder loss of cardiac reserve. Five suffered a cerebral accident or attacks of hypertensive encephalopathy. One had arteriosclerotic gangrene and showed glycosuria. Three were untraced. Nine have died cause unknown four, cerebral accident three, probable uremia one, postoperative one. Excluding the postoperative death seven females died, and one male. Four of these severe cases were called malignant, three of them females. The course was relatively short in three of these. In the fourth the malignant phase came at the end of thirteen years' known hypertension. It is apparent that mild or moderate hypertension occurs at this age in females but that when one sees hypertension clinically at this age, in females, it is likely to be severe or malignant. As pointed out above, abnormal

catamema or toxemia of pregnancy are often found in the past history.

We have studied 134 patients over forty five years of age. One case was unclassified as to severity. Approximately 22 per cent (twenty nine cases) were mild, 42 per cent (fifty seven cases) were moderate, 35 per cent (forty seven cases) were severe. Hypertension was discovered by routine examination in ten of the mild group, four of the moderate, two of the severe. One death in the mild group was due to carcinoma. Two deaths among the moderate group were related to associated diseases, allergic asthma and rheumatic heart disease respectively. This group corresponds to the usual series of cases diagnosed essential hypertension females predominate almost two to one (forty-seven males, eighty-seven females), the course is long relatively benign, the mortality is somewhat higher among males.

Over forty five years of age there were forty seven with severe essential hypertension. Twenty three of these had congestive or anginal heart failure. Eleven had hypertensive encephalopathy or cerebral accident. There were twenty nine deaths of undetermined cause twelve actual or probable coronary thrombosis six, congestive heart failure four, cerebral accident four, uremia two. One patient died postoperatively. Excluding this death the mortality was 20.89 per cent. In this group the mortality for males was 23.4 per cent for females 19.54 per cent. There were five cases of malignant hypertension, one was aged fifty two, two were fifty and one each forty-eight and forty seven. Three were females, two males.

TABLE 2

DURATION OF BLOOD PRESSURE AND SYMPTOMS					
Severity	Classification Age	No of Cases	Average Duration in Years	Duration Five Years or Over	Duration Ten Years or Over
Mild	Under 36	34	3.7	10	
	36 to 45	9	4.5	8	
	Over 45	20	3.9	7	1
	All ages	53	3.9	20	1
Moderate	Under 36	6	2.7	1	
	36 to 45	6	4.0	2	
	Over 45	54	7.8	37	17
	All ages	66	7.0	40	17
Severe and Malignant	Under 36	10	3.8	3	1
	36 to 45	15	5.7	6	3
	Over 45	45	5.9	19	8
	All ages	70	5.6	28	12

Table 2 shows the average duration of the blood pressure in those cases followed over a longer period than the original observation in the various groups classified according to age and severity of the disease. The number of

cases in which the blood pressure lasted over five and over ten years is indicated. Inspection of these figures shows that the cases graded moderate have the longest course. Probably this is due to the fact that the malignant cases are characterized chiefly by an intense rapidly progressive short course. The short duration of the mild cases at all ages is presumably due to early observation in the course of the disease. Of interest is the large number of cases lasting over five years and the considerable number lasting ten or more years. Three patients in this series were known to have had abnormally high blood pressure over twenty years. These figures attest the fact that in general, essential hypertension pursues a long and benign course in most instances, a probable average of about ten years.

It is apparent that hypertension occurs at all ages and exhibits all gradations of severity and of intensity. At earlier ages our series is characterized by special selection of young adult males among whom an elevated blood pressure is frequently a sign of vasomotor instability, not true essential hypertension. When we have encountered elevated blood pressures clinically in women under forty-five years of age we have often found the rapid intense process known as malignant hypertension, the most severe form of the disease. Malignant hypertension has not occurred over fifty-two years of age in this series.

The severe cases of hypertension over forty-five have as a rule resulted from a long slowly progressive course. We are aware of the increased mortality rate of those with hypertension as compared with normal human beings and our mortality figures attest this fact. However, our prognosis must be based on the stage of the disease in which we see the patient and not on the findings in an exclusively late stage group such as those reported by White⁴ almost 90 per cent being over fifty years of age, the majority already having serious irreversible cardiovascular changes.

The experience of White⁴ and Lewis⁵ indicates that essential hypertension is commoner in males. We believe their figures are due to special selection, in that essential hypertension is more severe in males over forty-five years and it is for the late effects of hypertension that

they are consulted. Our figures and the weight of the evidence^{6, 7} indicate that essential hypertension at middle life and beyond is significantly greater in women though its course is more benign as compared with that in men.

Review of the clinical observations in 224 cases of abnormally high blood pressures at different ages followed for varying periods during the last five years suggests these conclusions:

1 Essential hypertension often exhibits an early variable stage, responding readily to simple medical measures, difficult to distinguish from vasomotor instability and simple emotional or functional disorders.

2 The primary factor in the etiology of essential hypertension is constitutional susceptibility.

3 Important precipitating or aggravating factors are nervous or emotional strain and in females abnormalities of catamenia, toxemia of pregnancy, the menopause and, possibly, pyelitis.

4 Beyond forty-five years of age the disease appears to be more serious among males, but under forty-five years the severest form of essential hypertension, especially the malignant phase of the disease, in our experience is more common in females.

5 The average known duration of essential hypertension in the usual case, not in the malignant phase, is four to eight years but cases lasting ten years are not infrequent and occasional cases lasting twenty years are seen.

6 Our findings stress the importance of early diagnosis for the purpose of therapeutic intervention before late irreversible changes have taken place.

ASTHENIA HYPOPHYSOPRIVA

Neuromuscular Symptoms Due To Alterations In The Pituitary

BY BERNARDO A. HOUSAT, M.D.†

ASTHENIA is one of the most interesting symptoms of pituitary insufficiency it always occurs in the toad and though in a lesser degree, in the rat, it manifests itself in man in the course of pituitary cachexia and is also seen, with varying frequency, in other species. It is well marked in the advanced stages of severe forms of pituitary insufficiency consisting with general and metabolic symptoms and with modifications of behavior in animals and of mental reactions in man. It seems to be the result of a general nutritive change, which principally affects the central nervous system but also affects the chemical reactions of the muscles. The toad is the animal *par excellence* for the observation and analysis of this phenomenon.

Experimental pituitary insufficiency

Dogs—After removal of the pituitary gland in dogs some symptoms appear immediately, others do not occur until later. The former described by Vassale and Sacchi,¹¹ are depression, apathy, tameness, docility and passivity, sleepiness, fibrillary muscular contractions, rigidity of the hind legs, arching of the back, halting gait, sometimes tonic-clonic convulsions during which death may occur, anorexia with occasional vomiting, frequently polyuria and polydipsia, rapid and progressive wasting. The following symptoms have been observed by many investigators: (1) the depression, apathy or indifference is very frequent in the first days after operation^{11, 22, 4} 31, 32, 46, 47, 117, etc., although in our experience it varies considerably in degree, (2) a lowering of temperature is not rare^{47, 41, 51, 109, 117, etc.} particularly in the fatal cases, (3) lethargy or somnolence are very common and at times extreme but are transient, (4) loss of weight or cachexia—^{24, 31, 41} have not been very marked in our observations except in cases with polyuria and anorexia, (5) motor symptoms, i.e. contractions, rigidity of the neck, fibrillary twitchings, curving of the back, hanging of the head, usually do not occur if the operation has been performed with care. The defecatory attitude, associated with apathy, low temperature and low blood pressure, followed by coma and death, which Cushing and his collaborators consider typical of the cachexia of pituitary insufficiency, is also produced by lesions in the neighborhood

of the pituitary³⁷ or by tubular puncture which does not touch the pituitary.⁷ We can definitely state from wide experience that these symptoms are observed more often and with greater intensity (particularly the convulsions and motor symptoms) when tubular lesions occur or when blood clots are left in the sella turcica while there is only slight depression (inconstant in puppies) and sleepiness, and slight loss of appetite if the pituitary is removed skillfully with minimum trauma.

The late symptoms that is to say those occurring when the dogs have recovered from the first operative effects, are more interesting. Caselli²² observed psychic depression, in that the dogs were apathetic, quiet, patient, their intelligence dull and their gait slow. Crowe, Cushing and Homans⁷ observed adiposity and genital atrophy and often psychical depression with inactivity and somnolence, although certain of their dogs played ceaselessly and many were irritable. Aschner³ mentioned slight depression in the adult with a decrease though never a complete suppression of the sexual impulses, puppies were quiet, moved little and had sluggish tempers. Ascoli and Legnani² mentioned the psychical and physical weakness, Koster and Geesink⁴⁶ and Reichert²³ described loss of vivacity. Since 1912 we have found that some animals are apathetic and sleep much of the time, being patient and little responsive to stimuli (either pleasant or unpleasant) but others retain their vivacity and like to play. There are many intermediate degrees between these two extremes.

In general the hypophysectomized animals are docile, tame and quiet, and easily trained to remain immobile. The intense degree of depression may be observed also in certain dogs with tubular lesions, while others of these may become irritable, savage and wild, or on the contrary very timid.¹⁰⁹

Although the tameness and docility are frequent and significant in hypophysectomized animals, one cannot speak of real asthenia or cachexia as occurring in all of the animals. Nevertheless, from time to time even when in apparently good condition, they may spontaneously or as a result of some infection, trauma or fasting become anorectic, apathetic and progressively cachectic, dying in a marasmic condition with or without hypoglycemia. In other similar cases death may suddenly occur in hypoglycemic or repeated epileptoid convulsions.

†Housat, Bernardo A.—Professor of Physiology, Faculty of Medical Sciences, University of Buenos Aires, 1912. For record and address of author see "This Week's Issue," page 946, issue of May 7.

¹Maloney⁷ found a marked hypoglycemia which he considered the cause of death; sugar produced an improvement in the condition of the animal.

The conditioned reflexes were studied by Kriaschew⁶⁸ in two dogs. He found that they behaved in an infantile fashion and showed a general diminution of excitability and a diminished electrical excitability of the skin. Conditioned reflexes were produced by different stimuli (cutaneous, auditory and visual), but there were certain peculiarities, (1) irradiation was diminished, e.g., only the stimulated paw responded instead of the reaction becoming generalized, (2) the response ended directly the stimulus was removed, which is contrary to what occurs in normal animals, (3) there was a rapid disappearance of the conditioned reflex. Cortical co-ordination was weak and the sexual reflexes, cries, etc., were absent. The higher nervous activities seemed to become fragmentary with almost complete independence of the cortical centres and their reflex function. A histological study was made five and a half years after the operation (removal of the pituitary and lesion of the tuberal region) revealing pathologic degenerative changes in the cortex and hypothalamus.

Horsley,⁴⁰ in two dogs five to six months after hypophysectomy, observed that there was hyperexcitability of the motor cortex to faradic stimulation, which produced a severe tetanus followed by protracted and severe epilepsy (the most prolonged seen in dogs), with rapid clonic spasms (24 per second). This epilepsy ended "by the occurrence of a tremendous spasm, instead of a gradual dying out of the clonic spasm."

Pituitary insufficiency in animals produces an increased sensitivity to anesthetics, to blood sugar lowering agents (insulin, phlorhizin, etc.) and to blood pressure lowering agents (histamin, bleeding, etc.). Hypophysectomized dogs are extremely sensitive to the toxic action of chloralose. Our mortality for the first week after operation dropped from 75 per cent to 15 per cent when, in 1932, we substituted ether for chloralose anesthesia. (On the other hand animals treated with thyroid or thyrotropic hormone require a larger dose of chloralose than normally.) Two out of ten hypophysectomized dogs showed grave symptoms with only 30 Mgm of morphine hydrochloride per Kgm body weight subcutaneously, and one died (di Benedetto, unpublished).

Rats—Hypophysectomized rats are weak, unsteady, and less active, they lose weight and become cachectic. They grow prematurely senile according to Smith¹⁰⁷⁻¹⁰⁸. Koyama⁶⁷ found asthenia lessened muscular turgidity and later cachexia. The loss of activity has been recorded graphically by Richter and Wislocki.^{96*} Implantation of the pituitary gland corrects

all the symptoms.¹⁰⁷⁻¹⁰⁸ Alkaline extract of bovine anterior pituitary lobe immediately tends to restore the strength, muscular tone and turgidity of the tissues in all cases, so that within ten days of its administration the characteristic myasthenia of hypophysectomized animals disappears.³⁷⁻³⁸ The gonadotropic extract, however, does not alter these symptoms.³⁸ Asthenia is not caused by ablation of the posterior lobe¹⁰³ or by partial hypophysectomy.

Other species—Hypophysectomized cats, some time after the operation, feed well but are apathetic and less playful than are normal cats.⁷⁷ Rabbits may appear cachectic within a few days⁹⁸⁻⁹⁹ or improve and appear normal for some time, but later again become indolent¹¹⁹ or even cachectic.

The hypophysectomized ferret cannot be distinguished from the normal except for being somewhat lethargic.⁴⁸ Hypophysectomized chickens usually die in forty-eight hours, sometimes in convulsions, those which survive are not quarrelsome though they will still fight.⁴⁷

Toads A neuromuscular syndrome appears in hypophysectomized amphibians some weeks after operation and gradually becomes worse terminating in death.* It is necessary to differentiate this syndrome from certain initial or early symptoms which may occur.

The initial symptoms are rare and are due to lesions of the nervous system at operation, the animals become enormously distended owing to urine in the paralyzed bladder, they become paretic, with the legs abducted, sometimes they have opisthotonos with infrequent movements at other times there are tonic and tonoclonic convulsions. Most animals with these symptoms die in a few days, but a small number recover.

On the other hand hypophysectomized toads (or toads from which the principal lobe has been removed) always become asthenic or adynamic at a later stage. The asthenia makes its appearance in from ten to fifteen days after total hypophysectomy. When only the principal lobe is removed it occurs a little later, although more than half of the animals have asthenia by the end of the third postoperative week. Death occurs three to thirty days after the appearance of the asthenia, most of the toads dying between four and seven weeks after operation.† This is rarely observed in toads with lesions of the infundibulotuberal region (10-15 per cent in two of our groups). The asthenia of

*This has been observed in *Leptodactylus ocellatus* to 11 in *Bufo arenarum* Hensell 23 36 and in *Bufo d'Orbigny*, *Ceratophrys ornata* and *Hyla* sp 62 63

†In our experience exceptional cases developed no asthenia and survived for three or even five and a half months. Anatomical examination of these disclosed that though the principal lobe had been removed the neuro intermediate lobe was conserved and showed certain peculiarities. In a few places in the *pars intermedia* there were groups of two to six acidophilic and basophilic cells. It is possible that in these animals the neuro-intermediate lobe probably the *pars intermedia* took over the metabolic functions of the absent glandular lobe.

*Tuberal lesions (with section of the pituitary stalk) produce a decrease in spontaneous movements alternating with cycles of activity lasting nine to eighteen days.⁹⁵

the latter preparations was in consequence of secondary destructive lesions of the principal lobe of the pituitary.^{64, 70}

After asthenia has developed certain minor remissions and relapses are to be noted but the general course is downwards terminating in death. The first symptom to appear is an al

since reactions with rapid, forceful movements to other stimuli are still possible.

Later in the course of the asthenia the resting posture and the gait alter. When at rest the head is held lower, the legs more abducted and the muscles more flaccid than is the case in normal animals. All movements are slow and

FIG. 1.

Asthenia hypophysegriva in the toad showing typical postures and the loss of the righting reflex.

teration in the postural reflex whereby the normal position is regained when the toad is placed on its back. At first the animal is able to turn over in a few seconds but as the asthenia progresses it remains longer and longer on its back with the four legs flexed and contracted on the body or, more rarely, extended. (Fig. 1) Grotesque, catatonic movements may be observed. After some minutes the animal succeeds with some difficulty in righting itself. The failure of this postural reflex is not due to paralysis,

progression is effected by crawling instead of by the normal jumping. The croaking reflex, however, persists. As the asthenia and adynamia progress the lack of movement becomes so complete that only the heart beats give signs of life.

Convulsions may be observed during any stage of the asthenia. They resemble those of strychnine and even more closely, those due to insulin. The hind legs kick together or separately, the fore legs cross each other, there are tonic

spasms separated by clonic ones or by periods of paralysis. These convulsions are usually observed in 3 to 10 per cent of the preparations, but in one group they reached 50 per cent. Feeding (with ox or frogs' meat or frogs' liver or worms) aggravates the convulsions and causes them to become more frequent.

The asthenic symptoms may be prevented by implantation or injection of the principal lobe of the toad, or of the neuro-intermediate lobe. The latter is less active as are also both mammalian anterior and posterior lobes.^{52 53 56 60 114} If the asthenia and convulsions are not very severe these injections or implantations will cure them. They will also prevent or counteract the toxic effect of insulin.⁶⁰ On the other hand the asthenia is not checked or cured by glucose, adrenin or cortin, indeed, the adrenals of asthenic toads fifty days after operation have the same amount of adrenin as have the controls.^{52 53 58}

The asthenia is due to metabolic alterations which affect the central nervous functions first and later, to a lesser degree, the muscular. That this is so is proved by the following facts: (1) The first sign is an alteration of the postural reflex which occurs even while movement is forceful, sensitiveness is preserved and the gait is normal. (2) The convulsions occur together with the asthenia, their origin is central because they cease in either limb when the mo-

Abscissae—Time in days

Ordinates—Mgm P per 100 Gm muscle

for nerves are cut. (3) There is a more rapid fatigue in the reflexes following acid (Houssey) or electrical stimulation,²⁵ and the reflexes disappear altogether in severe asthenia.²⁵ (4) Centripetal stimulation of the sciatic nerve causes, besides the rapid fatigue of the crossed reflex, rise and instability of the rheobase. (5) There is a quite exact correlation between the appearance of these changes and the asthenia. (6) The muscular and nervous chronaxie is normal except for an increase in both rheobase and chronaxie of the muscles when the asthenia becomes extreme.⁶ (7) When the asthenia is well developed the ergographic curve* of the gastrocnemius, on stimulation of the sciatic gives 74 to 80 per cent of work in the hypophysectomized and 86 to 95 per cent in those with le-

FIG. 4

sions of the tuber, as compared with that given by craniotomized animals.^{23 24 27}

The general and muscular metabolic changes have been studied, but those of the central nervous system have not. The alterations occurring in hypophysectomized toads, or in those with out the anterior lobe can be prevented or corrected (partly or entirely) by mammalian anterior pituitary lobe or by the principal lobe of the toad, the posterior mammalian lobe and the neuro-intermediate toad lobe have a less effective action.† The metabolic changes which have been found are as follows: (1) The blood sugar is slightly lowered.^{25 26} (Fig. 2) (2) The glycogen decreases earliest, and to the greatest extent, in the liver.^{25 26} later in the heart²⁶ and finally, but to a lesser degree in the muscles.^{25 26} (Fig. 2) (3) The phosphocreatine (and also the total phosphorus) of the muscles is lowered, particularly during the second

Neuromotor and psychic changes in man

Pituitary cachexia or Simmonds' disease is seen in patients with serious destructive lesions of the pituitary.* The symptomatology has been reviewed by Granbner,²⁸ Calder,²⁹ and Silver,³⁰ who have gathered together and analyzed several dozen published cases. The principal symptoms noted and somewhat variously described by a number of authors include the following: a progressive wasting which may lead to extreme emaciation, loss of the hair and changes in the skin, marked muscular weakness, asthenia and even intense adynamia, mental weakness, apathy or indifference or mental changes varying from stupidity to intense excitement and sometimes alterations of personality, states of collapse, giddiness and fainting fits, an appearance of premature senility, loss of appetite, digestive upsets, sexual changes particularly amenorrhea, frigidity and impotence, lowered B. M. R. and lessening of the specific dynamic action of foods, lowering of body temperature and blood pressure, hypersensitivity to insulin,

*The asterisk is a smaller number with cerebral or tuber lesions (see Pend. Revi. w. 100 to 105).

sometimes convulsions and sleepiness, and even coma and death^{1 4 9 13 15 17 18 19, 20 23 29 35 39 43 54 55 69 71 72 75 82 88 94 102 104 105 111 113 115 116 121 etc}

In many cases of the polyglandular endocrine insufficiency of Claude and Gougeot the pituitary hypofunction no doubt plays the leading part

In patients in whom the pituitary has been removed the following symptoms have been observed: indolence, extreme psychic changes, sleepiness, immobility, lowered temperature, etc.¹⁵ Various cases suffering from pituitary insufficiency and even cases of myasthenia gravis¹⁰⁰ have been improved with whole or anterior pituitary lobe^{1 14 17 18 23 25 26 61 65 76 92 94 112 etc}. Falta³⁹ has noted apathy and mental symptoms in cases of dystrophia adiposogenitalis. In cases of pituitary infantilism there is a persistence of the infantile mentality.

Soon after the discovery of acromegaly, attention was drawn to the frequency with which it was accompanied by mental changes.^{10 16} Brunet found them in ten of the thirty-eight cases described in the thesis written by Souza Leite under the direction of Pierre Marie. Brunet differentiates those symptoms which are typical of the disease (weakening of the intellect and memory, apathy, somnolence, obtuseness) and those due to mental degeneration from hereditary or other causes (misanthropy, hypochondria, melancholia, suicidal mania). Mark,⁸¹ an English doctor, made an interesting study of his own symptoms noting in particular the asthenia, feeling of tiredness, loss of energy, etc. Atkinson⁶ has made a summary of all the literature on the subject.

Cushing²⁸ declared that a large number of the patients with pituitary disease show mental irregularities of one or another nature. From the etiologic point of view there are two types: (1) those in which there is involvement of the temporal or frontal lobes or other areas due to invasion by or pressure from the tumors, (2) those where there is increase, alteration or insufficiency of the secretion. Patients with pituitary overactivity suffer from inability to concentrate, indecision, and psychasthenic states. If the illness originates in childhood there is a low grade of intelligence. In cases of pituitary insufficiency there can be all stages of mental change from light psychoses to extreme mental alteration. Some patients with pituitary disease have epilepsy.

Many investigators attribute a leading rôle to the diencephalon since analogous symptoms occur in cases with lesions of the third ventricle or cerebral peduncles and, above all, in encephalitis lethargica. According to them there are lower and higher psychic centres,^{21 34 74} and centres for the affections, impulses, desires, and

nutritive or vegetative functions.⁷² Cases of tumor of the third ventricle or tumors causing pressure on the diencephalon according to Camauei¹⁹ are characterized by apathy, mental confusion, an indifferent or masklike face, loss of memory, anorexia, sluggish sexual impulses, incoherence and confused states, flight of ideas, etc.

A certain number of cases of pituitary tumor collected by Salmon¹⁰⁰ show sleepiness but the experimental⁴⁶ and clinical data^{20 36 73} indicate that this is due to the concomitant diencephalic lesions. The phantastic theory put forward by Zondek and Bier (1932) concerning the existence of a pituitary hypnotic hormone has no serious chemical basis.

Certain diencephalic lesions can give rise to epileptic convulsions⁸³ which have been observed in human beings,⁸⁰ and lead some investigators to believe there is an epileptogenic centre.¹⁰¹

Pituitary asthenia and the adrenals

Pituitary insufficiency always causes atrophy of the adrenal cortex* (particularly of the internal layers) in the rat and less frequently in the dog. It has been observed in human hypopituitarism but has not been proved to exist in the toad.

Because of this, some investigators think pituitary cachexia is due to the accompanying adrenal insufficiency. Evans, Meyer, Pencharz, and Simpson^{37 38} observed that certain anterior pituitary extracts (but not the gonadotropic one) prevented or corrected the adrenal cortical atrophy and simultaneously the asthenia in hypophysectomized rats, with the result that the muscular force, tone and turgidity were surprisingly improved. These authors failed to obtain equivalent results by the use of cortin, although others have done so, e.g., Atwell⁶ found that the asthenia and lowered temperature were improved and there was a partial recovery of spontaneous activity, without, however, any alteration in the atrophy of the adrenals. Perla⁹⁰ found that there was an increased resistance to the toxic action of histamine, Baird, Cloney and Albright⁸ found disappearance of the extreme sensitiveness to cold, and Kalk⁹³ was able, by using cortin, to improve a case of human pituitary cachexia which had been resistant to anterior pituitary extracts. Cortin also seems to diminish the high postoperative mortality in hypophysectomized chickens⁴⁷ but I have not found any benefit from its use in the asthenia of toads.

Injection of anterior pituitary extract does not prolong the life of adrenalectomized rats,³⁶ dogs or toads (Houssay and Leloir, unpublished).

Grollman and Firor⁴⁴ draw attention to the

*See our paper²² (with detailed bibliography) on the functional relations between the pituitary and the adrenals.

similarity between the symptoms of pituitary cachexia and chronic adrenal insufficiency. They were able to improve cases of the latter with anterior pituitary extract but not with adrenal cortical extract* thus giving rise to the supposition that the adrenal insufficiency causes some pituitary alteration leading to hypofunction which is manifested by stoppage of growth, reproductive incapacity and lowered temperature.

Certain cases of pituitary basophilism have shown asthenia, and extreme weakness. Cushig¹⁰ suggests that these symptoms have an adrenal origin.

GENERAL SUMMARY

In the advanced stages of confirmed pituitary insufficiency there is a neuromuscular asthenic syndrome which occurs constantly in tensely and characteristically in the toad, during certain stages in the rat, and in a less marked form and not so constantly in the dog. It is very well developed in human cases of pituitary cachexia.

The syndrome seems to result mainly from functional changes in the central nervous system, the peripheral motor changes playing only a secondary rôle. Evidence for this is given by (1) the experimental analysis carried out in the asthenic toad, (2) the early and marked alteration in the postural and phasic reflexes in these toads, while the motor nerve and muscular excitability is still normal, (3) the coexistence of convulsions of central nervous origin with the asthenia, (4) the association with mental alterations in human cachexia and the changes in behavior of other animals, (5) the lowered blood pressure and hypodynamic vascular reactions. (See our lecture on, Hypophysis and Blood Pressure.)

The functional changes seem to have a metabolic origin since they coincide with general nutritive changes (decrease of blood sugar and glycogen, increase of sensitivity to insulin, decrease of the endogenous nitrogenous catabolism, etc.).

Adrenal insufficiency which occurs frequently in cases of pituitary insufficiency probably increases the asthenia but it is not certain, nor even likely, that the asthenia has an exclusively adrenal origin. Cortin does not correct asthenia hypophysopriva as does the anterior pituitary extract. It is more probable that there is a direct metabolic action of the pituitary hormone. On the other hand the actions of the adrenals and pituitary on the carbohydrate metabolism have a certain similarity (the glyco-genetic action, etc.) and anterior pituitary extract has a diabetogenic activity in adrenalectomized toads.

Pituitary asthenia therefore appears to be due to general nutritive changes which principally affect the function of the central nervous system.

Committee of Arrangements*

THE ONE HUNDRED AND FIFTY-FIFTH ANNIVERSARY

Monday, Tuesday and Wednesday, June 8, 9, and 10, Hotel Kimball and
Municipal Auditorium, Springfield, Mass

EXTENSIVE preparations are being made to assure all the members of our State Medical Society and their families, one of the most enjoyable and instructive Annual Meetings ever held in the western part of Massachusetts

HOTEL KIMBALL

The beautiful city of Springfield, its doctors, nurses and hospitals, will welcome every individual member of the medical fraternity to the celebration of the Three Hundredth Anniversary of the founding of the City.

Your State Officers and the Committee of Ar

rangements have received splendid co-operation from the Editors of *The New England Journal of Medicine* and from the doctors of Springfield headed by Dr. Allen G. Rice.

An elaborate program is to be presented at the Section Meetings as well as at the Scientific Exhibits. A larger Commercial Exhibit will be presented than has ever been shown before. Fifty booths in this group will demonstrate the latest medicines, apparatus and aids to modern medical and surgical practice.

The new Springfield Auditorium makes an ideal building to house the Section Meetings as well as the Scientific and Commercial Exhibits.

Headquarters for our convention will be at the Hotel Kimball, Chestnut Street, Springfield and here the Cotting Luncheon, Annual Discourse, as well as the Annual Meeting and Dinner will be held.

A good-fellowship room will be maintained at the Hotel Kimball, for the benefit of our members and guests. Refreshments will be served after the Shattuck Lecture.

Let's all get together on June 8, 9, and 10 for a first-rate good time in Springfield.

GENERAL INFORMATION

A Bureau of Information will be maintained at the Registration Desk on the stage of the *Municipal Auditorium*. There will be a private telephone at the Bureau for the reception of calls for attending physicians. Physicians expecting to receive calls should leave proper information with the attendant.

Registration Fellows are requested to register at the Auditorium as soon as they arrive and to get their tickets for the Annual Dinner and for the Wednesday luncheon. The charge for the Annual Dinner will be \$1.00 to those who are not in arrears and the Wednesday luncheon will be without charge to those whose dues have been paid.

The Scientific Exhibits are all located in the Main Hall of the Auditorium. See page 1042 for list of Scientific Exhibits.

The Commercial Exhibits are all located in the

Main Hall of the Auditorium See page 1043 for list of Commercial Exhibitors

A special *Historical Medical Exhibit* has been prepared by the Local Committee of Arrangements, and will be found in Booth 71 in the Main Hall of the Auditorium.

The *Hobby Show* will be in Room C of the Auditorium

Section Meetings will be held in the Mahog any Room and the Lower Section Room of the Auditorium.

At the *Hotel Kimball* there will be held

- 1 The Supervising Censors' Meeting
- 2 The Council Meeting
- 3 The Annual Meeting of the Society
- 4 The Annual Dinner
- 5 The Cotting Luncheon
- 6 The Wednesday Luncheon
- 7 The Shattuck Lecture
- 8 The Annual Discourse

A *Good Fellowship Room* will be maintained by the Society on the second floor of the Hotel Kimball. The members are cordially invited to make use of this room.

Light refreshments will be served here after the Shattuck Lecture.

THE ANNUAL DINNER

Fellows wishing to sit together at the dinner please send their names to Dr W R Morrison, Chairman of the Committee of Arrangements, 8 Fenway, Boston, at the earliest possible moment, and proper reservations will be made

Tickets for the dinner should be obtained at the Registration Desk in the Auditorium

HOBBY EXHIBIT

HOBBYITES Opportunity hereby knocks at your door Send tangible evidence of your mechanism of escape to the Annual Hobby Show at the June Meeting of the Massachusetts Medical Society in Springfield It may prove helpful if not ornamental

Notice of your intentions should be sent to E P Bagg Jr, 207 Elm Street Holyoke Mass Exhibits should be sent to

Mr George M Blair Custodian Municipal Auditorium, Springfield, Mass Plainly marked for the Massachusetts Medical Society, not later than June 6

The Society will defray the cost of exhibition, including insurance, provided values are stated, but not the cost of transportation

TRANSPORTATION

Daily Bus will shuttle between Kimball Hotel and Auditorium beginning at eight thirty in the morning

Busses will leave Kimball Hotel at eight thirty for Wesson Memorial Mercy, Shrine, and Springfield Hospitals returning from these hospitals at noon

Monday Bus will leave Kimball Hotel at 3 45 P M for the Springfield Country Club for those who wish to play golf, returning in time for the evening meeting

Maps Small maps will be at the Registration Desk showing the locations of hotels, Auditorium, and hospitals.

Parking Spaces Reserved near Kimball Hotel and Auditorium

Get a wind shield sticker at the registration desk.

HISTORICAL EXHIBIT

Grouped about six illustrated panels, will be placed old instruments, cases saddle-bags, etc having to do with the progress and development of the practice of medicine Will those having any such in their possession kindly write to Dr George L Schadt, 44 Chestnut Street, Springfield Massachusetts All objects lent for this exhibition will be insured, guarded by a watchman, and exhibited under glass

This exhibit will be found in Booth 71.

GOLF

A Kickers Golf Tournament has been arranged by the Local Committee under the chairmanship of R A Rockford This tournament will be played over the beautiful course of the Springfield Country Club at four o'clock on Monday afternoon, June 8

It is hoped that all golfers regardless of their ability, will enter this tournament The more players, the more fun

A bus will leave the Hotel Kimball at 3-45 P M for the Country Club, for the convenience of those who wish to play They will return in time for the evening meeting at the hotel

Players will have to pay their own greens fees, and may at their own expense have dinner at the Club

The prizes, which have been donated by the Springfield Druggists' Association, will be awarded at this dinner

Gordon M Morrison of Boston has also collected some additional prizes that will be presented at the same time

THE COMMITTEE ON POSTGRADUATE INSTRUCTION

This committee plans to have a luncheon on Monday June 8 at 12 30 o'clock in Springfield during the meetings of the Massachusetts Medical Society The details of the luncheon will be announced

HOSPITALS OF SPRINGFIELD

THE SPRINGFIELD HOSPITAL, 759 Chestnut Street

Originally started as the City Hospital in 1869 on the Boston Road, this institution was incorporated as The Springfield Hospital in 1883 and established on its present site in buildings dedicated and opened for the reception of patients on May 4 1889. The original capacity of approximately fifty beds was increased according to the demands until 1932 when the new building accommodating 323 beds was opened.

In this modern building services are provided in medicine, surgery, cancer dermatology, diabetes, gynecology, psychology, neurology, ophthalmology, orthopedic surgery, otolaryngology, pediatrics, bronchoscopy, syphilis and urology.

returned from the Cuban war. In the course of years it was gradually expanded until it can now adequately accommodate 330 patients and fifty babies. The hospital is conducted by the Sisters of Providence, Roman Catholic. Services are provided in medicine, surgery, cancer, dermatology, orthopedics, otolaryngology, pediatrics, ophthalmology, diabetes, gynecology, neurology, obstetrics and urology. Special departments: out-patient, school of nursing (est 1900), dietetic, x-ray, clinical and pathological laboratories, physical therapy, electrocardiograph, cancer clinic and organized library. Patients are admitted without regard to creed, race, color or financial resources. St. Mary's Maternity Hospital (fifty beds) is under the same management as The Mercy Hospital. Approved for standardization.

THE SPRINGFIELD HOSPITAL

Special departments: out-patient school of nursing (est 1892), social service, dietetic, physiotherapy, basal metabolism, electrocardiograph, cancer clinic, organized library, x-ray, clinical and pathological laboratories. The services of the hospital are given without regard to race, creed, color or pocketbook. This is a private, charitable organization controlled by a board of trustees. The hospital is approved for standardization by the American College of Surgeons, approved for general internship by the American Medical Association and is a member of the American Hospital Association.

Endowment \$1,476,535.04—value of grounds, buildings and equipment \$2,802,423.60. Patients admitted during 1935—5462; average daily number of patients 215; Internes—9.

THE MERCY HOSPITAL, 233 Carew Street

This hospital was opened in 1896 with a capacity of thirty beds and just in time to be of great benefit in caring for the American soldiers who

by the American College of Surgeons. Approved for general internship by the American Medical Association.

Value of grounds, buildings and equipment \$917,000.00. Patients admitted during 1935—5028; average daily number of patients—200; Internes—4.

HEALTH DEPARTMENT HOSPITAL, 1414 State Street

The first hospital was opened in 1899 with a bed capacity of twenty-four. Accommodations were gradually increased until the new Isolation Hospital was opened in 1931 with a capacity of ninety-six beds. Since 1934 the bed capacity in this new building has been equally divided between tubercular patients and those with other communicable diseases. The City of Springfield now has a municipal hospital for communicable diseases which is second to none and the city government should be congratulated on the far-sightedness shown in providing this accommodation.

tion Approved for standardization by the American College of Surgeons
Patients admitted in 1934—791 average daily number of patients—48 Internes— (one at a time)

CITY HOSPITAL 1400 State Street

A municipal hospital opened by the City of Springfield in 1906 to provide services in chronic and incurable diseases. It is conducted primarily for the indigent of the City at public expense. In 1933 an arrangement was made where by the bedridden patients were cared for in n

Admissions during 1935 were 2748—average daily number of patients 78 Internes—3

Approved for standardization by the American College of Surgeons approved for Internship by the American Medical Association in 1935 and is a member of the American Hospital Association

WESSON MATERNITY HOSPITAL 120 High Street

A specialized hospital opened in 1903 as a result of the generosity of Daniel Baird Wesson this hospital provides services for maternity cases only Special departments outpatient ambulat

THE MERCY HOSPITAL

chronic ward at The Springfield Hospital. In 1934 it had a capacity of 108 beds
Five hundred and nineteen patients were admitted in 1935 and it had a daily average of sixty eight patients Internes—none

WESSON MEMORIAL HOSPITAL, 140 High Street

In 1900 the Hampden Homeopathic Hospital was presented by Daniel Baird Wesson to his attending physician Dr. John H. Carmichael. The bed capacity of this hospital was twenty
In 1906 again through the generosity of Daniel Baird Wesson the present building was erected as a memorial to his wife Cynthia Maria Hawes, and the name changed to the Wesson Memorial Hospital

This is a general nonsectarian hospital of 120 beds and provides services in medicine surgery cancer dermatology diabetes gynecology neurology ophthalmology orthopedics otolaryngology pediatrics and urology Special departments outpatient dietetic x-ray pathological laboratory physiotherapy and bronchoscopy

ing school of nursing (est. 1900) and postgraduate school of nursing

Bed capacity 62 bassinets 66. Patients admitted in 1935—1491 Average daily number of patients—49 Internes—2

Approved for standardization by American College of Surgeons and is a member of the American Hospital Association

SHRINERS HOSPITAL FOR CRIPPLED CHILDREN 518 Carew Street

A specialized hospital. Services are limited to the rehabilitation of crippled children whose families are unable to pay. The expense of running this hospital is provided by the Shriners

Special departments outpatient and x-ray and pathological laboratories. Was opened on February 21, 1925 with a capacity of fifty beds. Patients admitted during the year 1935—400. Approved for standardization by the American College of Surgeons and is a member of the American Hospital Association

MEETINGS OF THE COUNCIL

The Annual Meeting, Tuesday, June 9, 1936 at 10:30 o'clock, in the Ballroom, Hotel Kimball. *Note Change of Time*

Other stated meetings in John Ware Hall Boston Medical Library 8 Fenway at noon on the first Wednesdays of October and February

CENSORS' MEETINGS

The Censors for the several districts will meet for the examination of applicants for Fellowship on the first Thursdays of May and November

The Censors for the Suffolk District will examine applicants residing in that district and also applicants who are non residents of Massachusetts

Applicants for Fellowship should apply to the Secretary of the District Society of the district in which they reside (have a legal residence) at least two weeks before the date of a given examination, taking with them their diplomas

TREASURER'S NOTICE

Assessments, payable in advance should be paid to the District Treasurer, or, in the case of non residents, to the Treasurer

Assessments were due January 1st. For the convenience of Fellows who have not yet paid, such assessments will be received for the Treasurer at the Registration Desk in the Springfield Auditorium

SECRETARY'S NOTICE

All communications as to membership especially changes of residence and address should be sent to the Secretary who keeps a constant

ly corrected official list of the Fellows and their addresses

Fellows are requested to see that their names and addresses are entered correctly in the Annual Directory and when they move to notify the Secretary. The Directory will be sent only to paid up Fellows

THE JOURNAL

The New England Journal of Medicine the official weekly organ of the Society, will be sent only to Fellows who have paid their assessments and to such Retired Fellows as may apply for it. Address communications to the Managing Editor of the Journal, Dr. Walter P. Bowers, 8 Fenway Boston

Society Headquarters
8 Fenway, Boston

COMMERCIAL EXHIBITS

The Commercial Exhibition at the Annual Meeting in Springfield will be comprised of forty-seven different exhibiting companies. The Committee of Arrangements takes more than ordinary pride in this announcement as it is the largest number of commercial exhibitors to attend a meeting of the Society. This exhibit, together with the booths for Registration and Information and the many scientific exhibits, will occupy the main floor of the Municipal Auditorium where the meetings are to be held.

It is difficult to visualize the practice of medicine and its specialties being carried on without the aid of commercial drug biological and medical supply houses. Their importance to our profession is manifold their contribution to the success of our meeting is obvious. In each of the booths occupied by a commercial exhibitor are contained useful therapeutic or diagnostic agents—all of which are worthy of the inspection and consideration of the attending physicians. In some instances displays will consist of finished products ready for clinical use in others the processes of manufacture will be demonstrated to give the visiting physicians a better understanding of the intricate problems which have been overcome to provide standardized reliable and readily available materials.

The co-operation between commercial laboratories and academic centers has resulted in untold benefits to every living being. Only by means of commercial development have many of the discoveries of science become of practical value to the vast majority of physicians and through them to mankind at large.

Regardless of your principal interests or specialties you will find much to attract your fancy among the commercial exhibits. We urge each and every Fellow attending the Meeting to visit this important display.

COMMERCIAL EXHIBITS

Booth
No.

1—General Electric X-Ray Corporation, Chicago

Manufacturers of x-ray and electro-medical apparatus will display shock proof x-ray apparatus x-ray films and equipment including "Maximar" unit for x-ray therapy

2—Thayer McNeil Company, Boston

Will again exhibit their Plastics for men, women and children, including several smart new models in their modified Plastics for women. The latter footwear has proved extremely popular with those who desire a dressy shoe that will help prevent, rather than correct, foot troubles. In addition to the full Plastic with its flexible shank, the Saf-T-Arch shoe, with a rigid shank, will be shown.

Mr Percy Thayer will be in charge

3—W B Saunders Company, Philadelphia and London

These publishers will exhibit a complete line of their 300 or more books. Outstanding among these will be Christopher's new "Textbook of Surgery", the new "Mayo Clinic Volume", Berens' work on "The Eye and its Diseases", Levine's work on "Heart Disease", the Graduate Fortnight of the New York Academy of Medicine on "Respiratory Diseases", Hinman's "Urology", Rehfuess and Nelson's "Medical Treatment of Gallbladder Disease", Eusterman and Balfour's "Stomach and Duodenum", and many new editions and standard works of unusual clinical value.

Mr J W Schnepf will be in charge

7—Dentists and Surgeons Supply Company, Springfield, Mass

Will display wood furniture for physicians' offices, the Vim Sheftel Colorimeter and surgical instruments.

Representatives Messrs Libby, White and Clarke

8—Gerber Products Company, Fremont, Michigan

Gerber's new method of shaker cooking will be explained. There will be illustrations and charts of this new process and samples open for inspection.

Booklets and leaflets will be available, some suitable for distribution by physicians while others are for professional use only.

Mr Howard Signor will be in charge

9, 10—E F Mahady Company, Boston

This exhibit will include a showing of the latest Burdick Physical Therapy equipment, Mahady Catgut, Baxter's Intravenous Solutions in Vacoliter Dispensers, and other new items of interest to the profession.

Messrs Kammerer Hartnett, and Graves will be in attendance

11—Mellin's Food Company Boston

The selection of Mellin's Food as a milk modifier enables the physician to have at hand an effective means for making diet adjustments to meet the needs of the individual infant without sacrificing nutritional requirements.

12—Einst Bischoff Company, New York City

Will exhibit their pharmaceutical specialties which are distributed through the drug trade. Their many products fill a wide range of professional needs.

Representatives Dr H H Newcomb and Mr L N Hosbach

13—S M A Corporation, Cleveland, Ohio

Will detail the significant resemblances of S M A to breast milk Smaco Carotene (Pro-Vitamine A), both plain and combined with Columbia and Zucker vitamin D concentrate.

Mr R E Esty will be in charge

14—H G Fischer Company, Inc, Chicago, Illinois

Will demonstrate electro-therapeutic equipment. A feature will be the new Fischer Short Wave high frequency apparatus, also the new Fischer 60 88 Universal shock proof diagnostic x-ray.

Representatives Messrs Wilson and Smyrl

18—Lee De Forest Laboratories Represented by New England X-Ray Corporation, Boston

This exhibit will consist of Short Wave therapy apparatus. The New England X-Ray Corp will also show products of the Standard X-Ray Co of Chicago, the largest exclusive manufacturers of x-ray equipment in the country.

19—Bard-Parker Company, Inc Danbury, Connecticut

Will feature the new Rib Back blade, an outstanding advance over the old flat detachable blade. A complete line of stainless steel Renewable Edge scissors. BP Germicide and instrument sterilizing containers will also be shown.

20—Mead Johnson and Company, Evansville, Indiana

Will feature in their display the new 'Percomorph' group of products. Mead's Oleum Percomorphum, 50 per cent in liquid and in capsule form, and Mead's Cod Liver Oil Fortified with Percomorph Liver Oil.

21 22—Davies, Rose and Company, Ltd, Boston

Will feature the well known Pli Digitalis (Davies, Rose) and Trethylene, a purified tri-chlorethylene for inhalation, and other therapeutic preparations.

Representatives Messrs Fleming, Purinton and Moulton

23—The C V Mosby Company, St Louis Mo

Will exhibit their complete line of medical publications among which will be many new books of laboratory methods, clinical medicine surgery, and various specialties. A few of the titles are Clendenen's "Methods of Treatment", Crossen's "Diseases of Women", Hansel's "Allergy of the Nose and Paranasal Sinuses", Hertzler's "Thyroid Gland", and Marriott's "Infant Nutrition".

Mr W Dobson will be in charge

24—The Arlington Chemical Company, Yonkers, N Y

Will have a display and demonstration of pollens and proteins with a free diagnostic pollen outfit for any particular botanical area—each set containing sufficient material for testing one hay fever patient. A group of their pharmaceuticals will also be exhibited.

Dr J H Frazer will be in attendance

25—M & R Dietetic Laboratories Inc., Columbus, Ohio

Will display Simlac, a completely modified milk for infants deprived of breast milk. Splintrate a spinach concentrate in both powder and tablet form will also be displayed. Mr J J Krancer will be in charge.

26—Crosbie Macdonald Boston

Crosbie-Macdonald who for over twenty five years have been serving members of the Massachusetts Medical Society in their insurance needs will be ready to explain the various forms of insurance. Representatives Messrs. Crosbie and Macdonald.

27—The E L Patch Company Boston

Will exhibit the leading medicinal specialties in the Patch line. The E L Patch Company is an old New England Pharmaceutical House, having served the Medical Profession for nearly fifty years. Their exhibit will be of interest and educational value to all physicians.

28—Middlewest Instrument Company, Chicago Illinois.

In this exhibit demonstrations and metabolism tests with the Jones Motor Basal Metabolism will be featured. This unit contains no water and requires no calculation in the determination of the basal metabolic rate. Representative Mr Leon Reiner.

29—Winthrop Chemical Company, Inc. New York City

Will exhibit among other preparations the new Winthrop products Driedol (Crystalline Vitamin D) in Propylene Glycol, the new non-oily antirachitic Devegan antienkorreptic specific Erypal Hypnotic Eripal Soluble in travenous anesthetic and Cyclobis bismuth antisyphilitic. Representatives Messrs McCormack and Lebar.

30—E R Squibb and Sons New York City

Will present the complete line of Squibb vitamin glandular arsenical and biological products and specialties as well as a number of interesting new items. Squibb representatives will be on hand to furnish information. Mr Percy S Braund will be in charge.

31—Tailby Nason Company, Boston

The Giant Cod and photographs of the Lofoten Fisheries in Norway will be an interesting part of the exhibit of Nason's Palatable Cod Liver Oil.

32—Kellogg Company Battle Creek Michigan

While enjoying a cup of Kellogg's Kaffee Hag Coffee you can see the display of other Kellogg products All Bran, Pep Bran, Flakes, Wheat Krahmbles, Corn Flakes, Rice Krispies, Whole Wheat Biscuit, Wheat Krispies and Whole Wheat Flakes. Miss Regina Gabriel will be in attendance.

33—Coca Cola Company Atlanta, Georgia

It is planned to serve Coca Cola complimentary from this booth the Coca Cola Company

recognizing that "The Pause That Refreshes" will be enjoyed by guests and visitors at the meeting.

34—Lea and Febiger, Philadelphia

Will have on display Hawes and Stone's Treatment of Pulmonary Tuberculosis, Graham Singer and Ballou's "Surgical Diseases of the Chest", Duncan's "Diabetes and Obesity" together with other new editions of well known medical publications. Representative Mr Walfred Larson.

35—The De Vilbiss Company Toledo, Ohio

Manufacturers of medicinal atomizers, will have on display a complete line of atomizers and vaporizers for home and professional use. A prominent feature will be the recently developed De Vilbiss Nasal Guard which prevents any excess pressure in the nasal passages during prescribed self treatment. Representative Mr E. Manning.

36—Surgeons' and Physicians' Supply Company, Boston

Will show the new Compress Short Wave Diathermy Apparatus, the McKesson Acumeter a new instrument for measuring the acuity of hearing and the McKesson metabolism outfit. Surgical instruments with many new and novel items will also be shown.

37—Nestle's Milk Products Inc. New York City

Will display Lactogen, Hyvac and Nestle's Food. A copy of an attractive new book on Infant Nutrition will be available to every interested physician who visits this booth. Representatives Messrs Goggin and Burrows.

38—Petrolagar Laboratories, Inc. Chicago

Will distribute samples and information on the five types of Petrolagar. Two of those Petrolagar Plain and Petrolagar Unsweetened are entirely without added medication. The other three, Petrolagar with Phenolphthalein, Petrolagar with Milk of Magnesia and Petrolagar with Milk Cascara are supplied to meet the indicated requirements. Representatives Messrs Aklin Tarplin and Gray.

39—Pomeroy Company Inc. New York City

Will show Pomeroy Frame Trusses, Artificial Limbs, Orthopedic Appliances, Sacro-Iliac and Lumbo-Sacral Supports, Foot Plates, Elastic Stockings and a variety of supporting belts. Representatives Messrs Lockwood and Bates.

40—Billhuber Knoll Corporation Jersey City New Jersey

Will exhibit their newer preparations Theocain for relieving dyspnea and edema in heart disease. Dilaudid hydrochloride a powerful analgesic for pain relief in surgery and obstetrics, cancer and terminal tuberculosis as well as a cough sedative. Bromural a non-barbiturate sedative and hypnotic and Metrazol a cardiorespiratory stimulant. Representatives Messrs Moore and Parker.

41—Horlick's Malted Corporation, Racine, Wisconsin

Will demonstrate the advantages of Horlick's Malted Milk in the liquid diet, notably in cases of tuberculosis and other wasting diseases, pneumonia, peptic ulcers and acidosis. It is a dependable food in infant feeding.

42—Lepel High Frequency Laboratories, Inc., New York City

Will exhibit their Ultra Short Wave Machine which combines five valuable modalities in the one unit. They will also exhibit their Quartz Mercury Ultraviolet Lamps. All these units are accepted by the Council on Physical Therapy of the American Medical Association.

43—H J Heinz Company, Pittsburgh

Will display their Tomato Juice, Breakfast Cereals and Strained Foods prepared especially for infant and convalescent feeding. Their revised edition of Nutritional Charts contains Vitamin, Mineral and Food Composition Charts and new sections on daily requirements and food allergy.

Miss Meredith Moulton will be in attendance.

47—Daylight Fluoroscope Corporation, Cambridge Mass

The Daylight Fluoroscope is a portable x ray proof fluoroscope which can be used in the operating room without the necessity of a dark room or in the ward or home. Can be used with any type of x ray apparatus.

The observer never looks in the path of the direct ray, but is protected against both direct and secondary rays.

Particular fields of usefulness—fractures and foreign bodies, especially of extremities.

48—Sandoz Chemical Company, New York City

Will display many of their more recently developed products, among which are Cal glucon, Gynergen, Digilanid, Scillaren and Bellergal.

49—The Medical Protective Company, Wheaton, Illinois

Will have representatives thoroughly trained in professional underwriting to discuss medical insurance problems. The most exacting requirements of adequate liability protection are those of the professional liability field. The Medical Protective Company have special facilities for this work.

50—Philip Morris & Co Ltd Inc, New York City

Will demonstrate the method by which it was found that Philip Morris cigarettes, in which diethylene glycol is used as the hygroscopic agent, are less irritating than cigarettes in which glycerine is employed.

51—Lederle Laboratories, Inc, New York City

Pollen Antigens Lederle, will be featured in this display which will also include highly refined Globulin Modified Antitoxins 1 cc Solution Liver Extract Immune Globulin (Human) for measles and other specialties.

Representatives Messrs Folsom and Caso

52—Libby, McNeill and Libby, Chicago, Illinois

Will present a graphical demonstration by means of photomicrographs of homogenization an outstanding advance in the science of infant feeding and special adult diets. By this process the food cells are "exploded" to release more nourishment for easy digestion while all coarse fibers are reduced to tiny particles.

Representative Mr Kelly C Brown

53—McNeil Laboratories, Philadelphia

Will show their American Medical Association Council accepted products and other specialties, including Digitalis Duo-test Lubricant, Rosebud Vaginal Tampons, Umbilical Dressings and "Individuals." Founded in 1879 McNeil Laboratories are well known among members of the medical profession from coast to coast.

54—The Macmillan Company, Publishers New York City

Will have on display among their new books Irving's "Textbook of Obstetrics", Kappers Huber Crosby's "Comparative Anatomy of the Nervous System" Johnson's "The True Physician" Houston's "The Art of Treatment" Cabot and Dicks' "The Art of Ministering to the Sick", and many other important publications.

Representative Mr J S Crossman

58, 59—Smith, Kline and French Laboratories Philadelphia

Will demonstrate by means of samples and literature their Benzadrine Inhaler, a potent vasoconstrictor which reduces congestion in the nasal passages promptly and without irritation, thus providing an effective and pleasant medication for head colds, sinusitis and hay fever.

Representatives Messrs Wallace and Hayward, Jr

60—Campbell X-Ray Company, Boston

Will exhibit new models of x ray apparatus also of short wave diathermy and electrosurgical appliances.

Table A

Sterisol Ampoule Corporation Long Island City, N Y

Manufacturers of prepared Dextrose and Saline solutions in PYREX containers hermetically sealed. These PYREX containers are available in 250 cc, 500 cc and 1000 cc sizes. Each container is a dispensing apparatus in itself. A complete range of Dextrose and Saline solutions as ordinarily administered is available.

Table F

The Cheney Chemical Company, Cleveland Ohio

Are desirous of drawing attention of the Medical Profession to the outstanding advantages of their products. Quantitative accuracy and the highest grade in quality are assured. Care is taken to safeguard the interests of

the physician while manufacturing products at as low a cost as possible. The doctors' satisfaction is our interest and we cordially invite all physicians to attend our booth.

MEETING OF DIPLOMATES OF THE NATIONAL BOARD

There will be a luncheon of the Massachusetts Diplomates, of the National Board of Medical Examiners, on Tuesday, June 9 from 12 to 2 P.M. at the Hotel Highland Hillman Street Springfield, Mass.

Diplomates will be present from every Medical District in Massachusetts. It is hoped that all Diplomates, attending the Annual Meeting of the Massachusetts Medical Society, will make a special effort to attend.

Details of this meeting will be announced.

MASSACHUSETTS MEDICO LEGAL SOCIETY

There will be a meeting of the Massachusetts Medico Legal Society in the Hotel Kimball Springfield, Mass., on Tuesday June 9 from 2 to 4 P.M.

TUFTS MEDICAL ALUMNI LUNCHEON

The annual luncheon of the Tufts Medical School Alumni Association will be held Monday, June 8 at 12 30 P.M. at Hotel Highland, Springfield. Graduates of the School attending the annual meeting of the Massachusetts Medical Society on this date are cordially invited to be present. The speakers will be Dean A. Warren Stearns, Dr. Abraham Myerson, and Mr. Oscar J. Mareil of the graduating class. The chairman of the committee on arrangements is Dr. Francis P. Boyd of 10 Chestnut Street, Springfield.

NEW ENGLAND ALUMNI—DINNER MEETING

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE
COLLEGE OF PHYSICIANS AND SURGEONS
BALTIMORE MEDICAL COLLEGE, BALTIMORE

Annual dinner at Hotel Highland, Springfield, Tuesday, June 9 at 12 30.

Dr. M. W. Harrington (B. M. C. 1901)

Dr. M. F. Hosmer (P. & S. 1914)

Dr. A. H. Riordan (U. of M. 1915)

Springfield Committee.

VITAMIN D AND TRICHINOSIS PATIENTS

Doses of vitamin D may be a means of preventing death and providing relief in trichinosis. If further experiments by Drs. Franklin D. Barker and Wayne W. Wantland, Northwestern University zoologists, prove successful.

The larvae of the worms make their way from the digestive tract to the muscles. As it does with all foreign substances that enter the muscles the body encloses these parasitic worm larvae with a coating of calcium as a protective measure. It takes from ten to fifteen months to do this. In the meantime, according to Dr. Wantland "It seems quite probable that the more general symptoms of trichinosis—muscular pains, fever, etc.—are in part at least, due to toxic products formed by the breaking down of large amounts of muscle tissue together with waste products of the larvae. Thus a continuous inoculation of the infected host with toxins occurs."

Vitamin D in the form of irradiated ergosterol definitely hastens the calcification of the trichina cysts in the muscle fibers during the critical stage of trichinosis in rabbits. It is hoped to accomplish the same results with the use of the vitamin in higher animals and eventually in man.

Making use of the property of vitamin D to stimulate calcium absorption from the intestine and calcium deposition in the body as is done in rickets, calcification of cysts containing the parasitic larvae has been brought about in from five to six weeks.

Dr. Barker and Dr. Wantland are now trying to determine whether the calcified cysts in the muscle fibers have any deleterious effect on higher animals.

There is a possibility that the particles in the tissue may cause a decrease in efficiency.

It is pointed out that it is significant that the majority of deaths from trichinosis occur from four to six weeks after infection during that period immediately preceding or during the earlier stages of cyst formation. It would seem that if cyst formation and subsequent calcification could be hastened this would shorten the critical period in trichinosis and more quickly terminate the disease. The treatment of trichinized rabbits with irradiated ergosterol apparently has a definite therapeutic value. It still remains to be tested in human cases of trichinosis.—*Science* May 1 1936.

RED MEN THRIVE

The erstwhile vanishing Indian now has a birth rate that is probably the highest in the world. The figure of 48 per 1,000 cited by Dr. Clark Wissler of Yale would be more than three times the urban birth rate for the whole United States. The death rate for the Indians has been declining since 1890, whereas the births are as numerous as they were at the beginning of the nineteenth century, almost 150 years ago. By now says Dr. Wissler the tribal existence has adjusted itself to the shock of reservation life.—*New York Times* May 4 1936.

THE LIABILITY TO INSANITY

The probabilities of going insane are three times greater if a man is a bachelor than if he is married and if he be divorced his chances are greater still.—*Bulletin* New York State Medical Society.

CASE RECORDS of the MASSACHUSETTS GENERAL HOSPITAL

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 22211

PRESENTATION OF CASE

A twenty-nine year old white American businessman was admitted complaining of shortness of breath and swelling of the abdomen.

The patient was perfectly well until a year and a half before admission, at which time he contracted "flu". His illness was associated with a temperature of 105° and sharp bilateral pleuritic pain which radiated anteriorly and posteriorly and was greatly aggravated by inspiratory movements. There was no sore throat, joint pain or cough. He remained in bed for three weeks but for the succeeding two months had considerable dyspnea with exertion. This gradually subsided and he remained well until two months prior to entry, when he again noted shortness of breath. The dyspnea increased and was excited eventually by such slight activity as walking a short distance during which he would be compelled to stop and rest for a few minutes. At this time he began also to have chilly sensations in the afternoon and consulted a physician who advised bed rest. He did not follow these instructions and four weeks ago his abdomen began to increase in size. He became progressively weaker and noted that when bending over his neck seemed to "fill up". He was admitted to a hospital where he remained for one week and was said to have had fever at that time. While there the abdominal swelling disappeared but after he returned home it promptly recurred. He reentered the hospital and soon developed sore throat and fever. The dyspnea was unchanged but he noted a "pulling" sensation beneath his sternum with deep inspiration. For two days before entry he coughed up a small amount of bloody sputum. His average weight was 145 pounds and at the time of his admission was 155 pounds.

Physical examination showed a pallid dyspneic man lying flat in bed. There was distention of the neck and hand veins, which persisted to a less degree when the patient sat upright. Venous pressure in the hands was found to be 20 to 25 centimeters of water. The retinal veins pulsated markedly with some relationship

to respiratory movements. The pharynx was injected and the tonsils were swollen. Small discrete cervical nodes were noted. The heart was said to be enlarged to the left and the right border of dullness extended 5 centimeters to the right of the midsternal line. The apex impulse was palpated and shifted with change in position of the patient. Other characteristics were not recorded. The sounds were distant and of poor quality. A friction rub was audible along the left border of the sternum. The blood pressure was 105/85 and a definite paradoxical pulse was observed on the sphygmomanometer. A pleural friction rub was heard over the right chest anteriorly and posteriorly. At the right base posteriorly there was dullness to flatness up to the sixth rib. In this region the breath sounds, tactile fremitus, and vocal resonance were diminished. The liver edge extended three fingerbreadths beneath the costal margin and there was a questionably enlarged spleen. The abdomen was distended and both shifting flank dullness and a fluid wave were elicited.

The temperature was 101°, the pulse 120. The respirations were 25.

Examination of the urine was negative. The blood showed a red cell count of 4,900,000 with a hemoglobin of 80 per cent. The white cell count was 9,400, 71 per cent polymorphonuclears. The sputum was mucoid, chocolate colored odorless, and negative for tubercle bacilli and amebae. Detailed examination demonstrated the presence of many bacteria of different types, large numbers of red blood cells, and many large macrophages with ingested red blood cells and blood pigment. Stool examinations were negative. A Hinton test was negative. The nonprotein nitrogen of the blood was 31 milligrams and the plasma protein was 5.6 grams. A tuberculin test was negative. An electrocardiogram showed a diphasic T₁ with late inversion of T₂ and T₃. There was a tendency toward low voltage. Q₄ was present and T₄ was upright. Seven hundred cubic centimeters of amber-colored fluid was removed by a right chest tap done shortly after entry. This had a specific gravity of 1.010, contained 30,000 red blood cells and 4,900 white blood cells, of which 91 per cent were polymorphonuclears. No tumor cells or bacteria were found. Culture showed no growth. A blood culture was negative.

An x-ray examination showed normal position and motion of the left diaphragm and a clear left lower lung field. The right lower lung field was dull and the outline of the diaphragm was obliterated at its lateral portion. The upper border of dullness was well defined and projected laterally and slightly downward from the hilus. There were several small areas of increased radiance in the lateral portion of this dullness and a large area of radiance close to the heart. The heart was slightly displaced

to the right and appeared somewhat enlarged. The remainder of the right lung field was less radiant than the left and there was a thickened lateral pleura extending up to the apex. Films taken after the thoracentesis showed very little sign of change. Two days later the amount of fluid had increased. A film taken with a Bucky diaphragm showed some apparent narrowing of the right lower lobe bronchus. Films of the skeletal system were negative.

The patient's temperature fluctuated between 98° and 103° and his pulse between 80 and 120. Venous pressure determinations showed a pressure of 11 millimeters of water on the dorsum of the foot and 23 millimeters in the right antecubital fossa. Subsequent thoracenteses were done but no additional findings were made. On the fourth hospital day an abdominal paracentesis was performed and only 20 cubic centimeters of pale yellow fluid removed. This had a specific gravity of 1.014 and contained 280 polymorphonuclears, 196 lymphocytes and 298 red blood cells per cubic millimeter. No tubercle bacilli, other bacteria, or tumor cells were found. Two days later a pericardial tap produced 110 cubic centimeters of cloudy reddish brown fluid with a specific gravity of 1.014. This fluid contained 69,000 red blood cells and 3 white blood cells per cubic millimeter. Examination for organisms and tumor cells was negative. The patient became progressively worse. His color became ashen gray and his respirations deep and labored. Repeated chest taps produced no relief nor did another pericardial tap. Pericardial fluid at this time was straw colored but showed no other change in characteristics. The paradoxical pulse became more pronounced and the neck veins remained distended though to a slightly less degree. On the ninth hospital day the patient lapsed into unconsciousness, developed marked grayish cyanosis, became pulseless and died within a very short time.

COMMENTS ON THE RECORD

DR. RICHARD C. CABOT: The shortness of breath is the presenting symptom and the chief symptom.

I find it rather hard looking back, to believe that he had no cough. But that is the statement.

'Small discrete cervical nodes were noted.' That makes one think of the possibility of malignant disease. There are no larger nodes elsewhere. We may as well say here that nothing else in the history suggests neoplasm.

You will notice that this cardiac examination is not what we would like. Who said that this heart was enlarged and why was he not more positive about it? We do not know.

A friction rub was audible along the left

border of the sternum." We do not know whether it was pericardial or pleural, presumably the former.

The blood is negative.

"A tuberculin test was negative." That seems to be of some importance.

Dr. White has been telling me what this electrocardiograph means. Apparently I do not have to say anything about it.

DR. PAUL D. WHITE: The T₄ is abnormal.

DR. CABOT: May we see the x-rays?

X-RAY INTERPRETATION

DR. AUREY O. HAMPTON: He had two examinations, one on the twenty-third and one on the twenty-fourth, one before and one after chest tap. This is the first film. It shows the area of dullness described at the right base. The upper margin is sharp as though it represented the interlobar pleura between the middle and upper lobes. This pleura should run horizontally when the film is taken in the usual position. It appears to be depressed and the lung is reduced in size. If the middle lobe was collapsed the right border of the heart should be obscured but here we do see a small portion of it. Of course the middle lobe does not ordinarily obscure the costophrenic angle so that I cannot say it is the middle lobe. It is hard for me to explain this line on any other basis though. His heart is shifted slightly toward the right. He is a little rotated and his heart does not appear particularly large. The blood vessel markings are prominent throughout the chest. The pulmonary conus is enlarged. I do not see anything else to remark about. This is a poor lateral view apparently; the patient was lying on a truck and it does not help us much. Apparently the dullness is more posterior than anterior. Again here is the middle lobe and it does not appear to be collapsed. Here is the fissure we were talking about, and here there must be some air in the middle lobe or we would not see these fissures. So we will have to place the dullness in the lower lobe where they found the physical signs. This is a film with the patient lying on his side after a tap. I suppose in an effort to show shift of fluid and there is this line along the axillary line which we had not seen before. There must be some shift in fluid. Of course you already know he had fluid.

DR. CABOT: One report says that there is apparent narrowing of the right lower lobe bronchus. That is something I imagine.

DR. HAMPTON: I did not have the Bucky film that is mentioned.

DR. CABOT: The films of the bones were negative.

You remember when he went to a previous hospital the ascites cleared up very quickly. It seems to have done the same here.

DIFFERENTIAL DIAGNOSIS

I suppose we have to call this a cardiac death, or a cardiac and pulmonary death, the cardiac being the main thing. What causes have we to consider here? We certainly have to consider pericardial adhesions in spite of the fact that the apex beat moves and in spite of the fact that the heart is apparently not very large. Many cases of pretty marked pericarditis have shown a movable apex beat. I do not think we have any good evidence of cirrhosis of the liver, although we would like to know more about his habits. Nothing is said as to whether he had that which apparently leads pretty often to cirrhosis of the liver. But I do not think we have good evidence of cirrhosis and I do not think that that diagnosis could explain more than a small portion of the case. The striking symptom is dyspnea and the striking lesions are those shown by the x-ray in the lower part of the right lung. I believe on the whole that whatever heart trouble he had was secondary to that rather than to pericardial adhesions, if those exist. I imagine he has some mediastinitis, too, although I have no proof of that. There are a number of points here often associated with pericarditis and with mediastinitis, such as paradoxical pulse and distended neck veins. But those can come from other causes, which make the respiration largely thoracic.

I do not believe he has malignant disease. There are a good many points in the history to make us think of that but it seems to me the x-ray and other evidence, his age, the absence of significant pressure signs, and the absence of pain make it wrong to consider malignant disease seriously. I believe the trouble is in his heart and lungs and only to a minor extent anywhere else.

In the paragraph about the x-ray, they mention small areas of increased radiance, I imagine these are what you get after tapping. If he had not been tapped I should be very much puzzled to explain the areas.

DR AUBREY O HAMPTON. It was a question of a patchy consolidation in the lower lung, one which probably left portions of the lung aerated. The middle lobe was fully aerated giving a shadow next to the heart a little like cavity because of the horizontal diaphragm below it.

DR CABOT. What has he in the right lung? That is the most important point. I think he has a chronic pneumonitis following pneumonia with a chronic pleurisy. That very possibly is present in both lungs but is probably more extensive on the right side. The chronic pneumonitis may have been such as to compress or obstruct a bronchus. There may be bronchiectasis with it but the striking primary thing I should suppose was the pneumonitis itself affect-

ing the bronchi and the parenchyma of the lung and indirectly affecting the heart. I should like to know more than we do about the left lung. X-ray and clinical examinations do not give evidence of damage there. If we are to make the lungs in part or largely responsible for the weakness of the heart, we would expect trouble on the other side too. That is the difficulty with that explanation.

Pericardial fluid was found. Therefore there were not complete pericardial adhesions. On the other hand the amount of fluid was rather small. The specific gravity of all the fluids, whether in the chest, pericardium or peritoneum, is low and so corresponds with a dropical fluid rather than with an inflammatory or neoplastic type of fluid.

He had fever at the end. Some acute infection is suggested. It might be that the sore throat and what was found in the pharynx and tonsils might be enough to account for it, or bronchopneumonia. Other than those I have no idea what was the acute disturbance on top of the chronic, but I believe he did die of both acute and chronic trouble.

I do not believe he had what is called polyserositis, a clinical syndrome with which I have never been very well satisfied. In polyserositis the symptoms are not primarily those of dyspnea, not primarily cardiac, as they are in this case. It seems to me that the prominence of the symptoms of failing compensation work against that diagnosis. He has, of course, fluid in at least three cavities and we have reason to believe that in at least one, possibly two inflammation has gone on. But the low gravity of the fluid and the predominance of the circulatory symptoms make it right to say that an inflammatory process in the serous cavities (polyserositis) was not the primary trouble here.

We must balance how much the pericardium and how much the lung troubles, respectively, are to blame for failure of the heart. I am assuming that he died of heart failure, with respiratory trouble too, but I am not at all sure how to balance the evidence or the conclusions between the pericardium and the lungs. I believe that each of these contributed something. I expect to see some pericardial adhesions. I do not expect to see complete pericardial adhesions. I do not believe that the pericardial adhesions were extensive enough to cause the main part of the cardiac failure. The lungs probably caused some of his dyspnea but I suppose both elements were in it.

There is no evidence of any valvular lesion. I suppose the heart is somewhat hypertrophied and dilated, although the x-ray does not give much support for that. I predict it will be found hypertrophied and dilated but not much

I see no reason to ocuse any other organs in the body, the kidneys or any other organ

I might say a bit more about the liver. The dullness and other respiratory signs in the back might be accounted for by an enlarged liver or trouble in the lung or by pleural fluid. Whether his liver had any more disease than passive congestion I doubt. I do not believe we have any good reason to suppose that the changes associated with Pick's disease are in this liver. I do not believe he had cirrhosis. He got rid of the abdominal fluid too easily. I should say. No one had to work to get fluid out of the abdomen. It went out twice easily. I do not suppose, therefore, that it was connected with disease of the liver.

DR. DONALD KING. I am glad Dr. Cabot came to this discussion without being prejudiced by the case which Dr. Mallory showed two weeks ago. We had a case, Dr. Cabot, of carcinoma of the right upper lobe with extensive metastasis to the pericardium. The pericardium contained a large amount of bloody fluid with resulting cardiac tamponade. A few days after this case was demonstrated here the present case was admitted to the hospital with the signs of cardiac tamponade and evidence of a process in the lungs, and the first thought of everyone was again of pulmonary carcinoma with metastasis. I think in the present case the service committed themselves definitely on a diagnosis of malignancy. Did they not, Dr. Mallory?

DR. THAC B. MALLORY. Yes. It was the final report.

DR. KING. None of us even guessed the final diagnosis.

DR. MALLORY. Are there any other suggestions?

DR. HAMPTON. I should like to ask Dr. King what he thought about the right lower lobe. Did he think it was collapsed?

DR. KING. We advised exploratory punctures to see if there was pus there. I thought it was infection of some sort, as Dr. Cabot did. We thought it might be malignant disease.

DR. WHITE. This case resembles very much a man who has recently been under our care, a young Canadian, who showed at autopsy tuberculosis of the pericardium and left pleura. He went through somewhat this same clinical course showing reddish and finally chocolate-colored pericardial fluid and eventually died of military tuberculosis. Dr. Tinsler Harrison of Nashville just whispered to me that if it were not for the tuberculin skin test he would feel quite sure that that would be the diagnosis here too, namely, tuberculosis of the pericardium and pleura. The signs of engorgement of the neck veins, the enlarged liver and the paradoxical pulse are in accord with constrictive pericardial involvement, acute or

chronic, or possibly of some lesion causing mediastinal pressure.

CLINICAL DIAGNOSIS

Carcinoma of the right lower bronchus with metastases to the pericardium and secondary atelectasis of the right lower lobe of the lung.

DR. RICHARD C. CABOT'S DIAGNOSES

Chronic pneumonia
Pericardial adhesions.
General passive congestion

ANATOMICAL DIAGNOSES

Pulmonary embolism, multiple bilateral
Pulmonary infarcts multiple, bilateral
Thrombophlebitis, left posttibial, popliteal and femoral veins
Pericarditis adhesive, localized
Pericardial effusion, slight
Hydrothorax, right
Ascites
Edema.
Chronic passive congestion liver, spleen and kidneys

PATHOLOGIC DISCUSSION

DR. MALLORY. Clinical imaginations at various times ran far afield on this man. We were even asked to do a sputum examination for *echinococcus scolices* on one occasion. The autopsy showed two entirely different lesions. There was a slight degree of adhesive pericarditis which was limited to a small area of the heart but it was the area which we have reason to believe is most important in other words, the base of the right auricle where the great vessels enter it. So a significant part of the symptomatology may have come from that.

A PHYSICIAN. Was that very old?

DR. MALLORY. It was evidently a very old process. I am inclined to think however that the major part of the symptomatology has nothing to do with this finding.

We found throughout the lung multiple areas of infarction varying from a very big infarct making up half of the right lower lobe, down to multiple small infarcts about a centimeter in diameter scattered throughout both right and left lungs. The microscopic sections of the lung showed all ages of pulmonary emboli. There are perfectly fresh ones and very old chronic, partially and completely organized ones. The immediate cause of death was massive pulmonary embolism. The source of these emboli was a thrombosis of the deep veins to the right leg. I think multiple successive pulmonary emboli with gradual organization and obliteration of one after another of the pulmonary arteries probably accounted for the right-sided heart

failure rather than the somewhat minimal amount of pericarditis, but I do not know

A PHYSICIAN Was this larger thrombus well organized?

DR MALLORY No, that was a fresh one. He had one episode about a year ago and I think some of the older lesions are consistent with that period. The majority are more recent, occurring undoubtedly during the last illness, and the final one was immediately fatal.

A PHYSICIAN What did the liver show?

DR MALLORY The liver was enlarged and showed marked passive congestion, but was otherwise negative. The heart was small, 250 grams. It must also be admitted that the right ventricle was not hypertrophied, a point distinctly against my theory of the relative significance of this man's pericardial and pulmonary lesions.

DR WHITE I would just like to call attention in passing to the electrocardiogram. A while ago we were studying the so-called acute cor pulmonale with dilatation of the right ventricle associated with pulmonary embolism. We found electrocardiographic changes that have proved to be characteristic of that condition. The electrocardiogram of the present case fills the bill perfectly, but I am afraid that we were so attracted by other ideas that we did not even think of the significance of this electrocardiogram.

CASE 22212

PRESENTATION OF CASE

A fifty-nine year old American building inspector was admitted complaining of difficulty in breathing.

About ten days before entry the patient developed malaise, chilly sensations, and a feeling of fullness in his chest. There was a slight cough but he was unable to expectorate. Later he developed generalized aching and had severe night sweats. A few days before entry he began to expectorate blood-streaked sputum. On the day prior to admission he had sharp pain in the right posterior chest and shoulder and also some pain in the right upper quadrant. Deep inspiration and cough caused intense exacerbation of the discomfort. During his illness the patient consumed about two quarts of whiskey as a therapeutic measure, but he did not drink liquor to any great extent ordinarily.

The patient had suffered from gout affecting both great toes for about twenty years and there was a brief acute flare-up during his current illness. Two years ago a physician told him he had pernicious anemia and advised him to eat liver. He did not follow these instructions.

Physical examination showed an obese mid-

dle-aged man sitting up in bed with a slightly increased respiratory rate and faintly cyanotic lips. Throughout the examination he was annoyed by a frequent, dry, irritative, nonproductive cough. Oral hygiene was poor and the tongue was coated and dry. The throat was injected and the tonsils large and cryptic. Patchy dullness to percussion was elicited over the right chest posteriorly and fine moist rales were heard at the left base, over the right lower lobe posteriorly, and the lower portion of the right chest anteriorly. Breath sounds in these areas varied from bronchovesicular to bronchial in character. The apex impulse was 9.5 centimeters to the left of the midsternal line but the heart border could not be percussed. The sounds were of poor quality, regular, and no murmurs were heard. The blood pressure was 154/90. The abdomen was distended and tympanitic but was otherwise negative.

The temperature was 102°, the pulse 130. The respirations were 30.

Examination of the urine was negative. The blood showed a red cell count of 4,800,000, with a hemoglobin of 85 per cent. The white cell count was 13,700, 85 per cent polymorphonuclears. Stool examinations were negative. The sputum contained type I pneumococci. A blood culture showed no growth. Uric acid was 3.9 milligrams per cent. A Hinton test was negative.

A portable x-ray film showed what appeared to be a high diaphragm bilaterally. The heart shadow was not distinctly seen. Hazy dullness was seen along the right costophrenic angle.

The patient's temperature fluctuated between 100° and 103° but after one week gradually returned to normal. Thereafter his condition gradually improved until the morning of the fourteenth hospital day, when he suddenly experienced rapid palpitation associated with nonradiating epigastric pain. Shortly afterward he had vertigo, profuse perspiration, blurring of vision and became semiconscious. An examination showed absent pulsations in the left brachial and radial arteries. The blood pressure was unchanged and the pulse 100. Later he vomited twice. Two and a half hours later examination of the heart was negative. The right carotid pulse was barely palpable although the left was normal. The left brachial, antecubital, and radial pulsations were not palpable, and this arm and hand were distinctly cooler than the right. The femoral pulsations were normal. There was a supranuclear paresis of the left side of the face and slight nystagmus of the right eye when turned toward the right. The reflexes were normal except for a questionable left Babinski sign. Later in the day the patient, except for severe right frontoparietal headache, was generally improved. The temperature in both arms was now approximately

equal and a faint pulsation was palpable in the lower portion of the right common carotid. The blood pressure on the right was 124/66. A faint pulsation was felt in the left axillary and brachial arteries but not distally. Blood pressure taken at the upper portion of the arm was 80/70. The mercury column oscillated at about 75 millimeters at the upper forearm but no sounds were heard. Examination of the urine was negative, but the white cell count of the blood, which had returned to normal rose to 13,400.

Portable x-ray films showed hozy homogeneous dullness occupying the lower third of the right lung field. This dullness ended in a sharp line above. This, however, was not in the same position in two films taken. The entire right lung field was less radiant than the left. The supracardiac shadow was wide but there was no definite thickening of the left wall of the arch. The ascending aorta was prominent and the heart was not grossly enlarged.

There was gradual improvement although the pulsation in the left arm did not return and the temperature began to show daily rises to 100° to 102°. Five days after the acute episode the patient was suddenly seized with a severe burning pain beneath the upper half of the sternum and a feeling of suffocation. He became intensely cyanotic and for about thirty seconds a clicking sound was heard with the stethoscope in the right supraclavicular fossa. The pulse was 120 and the blood pressure 130/70 on the right side. The pain in the chest disappeared rapidly following the administration of oxygen. Six hours later he had a similar attack associated with a burning sensation in the midabdomen. This was relieved somewhat by morphin. The blood pressure was 110/60 and the heart sounds appeared somewhat fainter than previously. Pulsation was still absent in the left arm but the carotid pulsation was much improved. An electrocardiogram showed upright T₁ and T₂, a small slurred Q₃. Q R-S₄ was widened but Q₄ was present and T₄ present though shallow. There were pain and tenderness over the left chest and marked tenderness over the left side of the abdomen and mid-portion of the lower abdomen. No definite change in the peripheral pulsations was noted. The patient remained in an oxygen tent and two days later suddenly became drowsy. Examination showed that the left facial weakness had progressed to well-defined paralysis and the tongue protruded to the left. The left arm was cooler and considerably weaker than the right but the leg was negative and there were no reflex changes. The pupils were small but equal and reacted normally to light. The cough, which had disappeared, now returned and was associated with mucoid expectoration with flecks of bright red blood. Repeated urine

examinations were negative but the white blood count rose to 16,500. Another x-ray showed that the dullness on the right side of the chest had almost disappeared but there was a new area of dullness on the left side at the costophrenic angle, and there appeared to be some fluid at the left base. The patient's condition continued poor, his abdomen became distended, and on the twenty-fourth hospital day he suddenly gasped a few times and died.

DIFFERENTIAL DIAGNOSIS

DR. HOWARD B. SPRAGUE Will you demonstrate the x-rays, Dr. Hampton?

DR. AUBREY O. HAMPTON We had three examinations. The first one was taken on the first of the month and the last on the twenty-third of the month. That film we thought was underexposed at the base and apparently unsatisfactory. There is nothing very exciting except this area of dullness at the right base.

This is the second examination, thirteen days later, and we see this triangular area of dullness here at the right base. It is more rectangular in shape in this other film taken the same day. I think due to shift in the patient. We had a very nice area of calcification in the arch of the aorta so that we could estimate the thickness of the left wall. We did not see anything else to remark about in this film. I think the shape of that lesion in the lung was quite similar to an infarct.

In this next examination the area of dullness at the right base has practically disappeared but he has a new one on the left side. It is in all appearances similar to the first one. There was at no time any change in the heart or mediastinum that we could see.

DR. SPRAGUE I can only hope that those who had the privilege of seeing the patient were as confused about the mechanism in this case as I. The only thing I am sure he had was gout and that only because they say he had it. I suspect however that the gout had something to do with his final taking off.

The story starts with what appears to be an acute respiratory infection with fever, cough and some blood-streaked sputum. We will allow that diagnosis to pass for the moment.

We know nothing about his past history aside from the gout except that some doctor two years before told him he had pernicious anemia and advised him to take liver. It may be that the patient at that time had some sort of appearance which suggested to the doctor that he had anemia. Perhaps he had some sort of cryptic hemorrhage from which he had recovered by the time he entered the hospital here because from the blood picture that we have we cannot make a diagnosis of pernicious anemia.

The patient apparently recovered to a considerable degree from his acute early pulmo-

BRAIN TUMORS LATE SURGICAL RESULTS

THE leading article* in this month's issue of the *Yale Journal of Biology and Medicine* calls attention to one of the uses to which the newly established registry for brain tumors at Yale, mentioned in these columns on December 13, 1934 has been put. Mr. Hugh Cairns, F.R.C.S., cerebral surgeon to the London Hospital came from London last autumn to study the end-results of the tumor cases that came under his supervision while acting as Dr. Cushing's resident at the Peter Bent Brigham Hospital nine years ago. This gives an indication of the purposes to which the collection may be put and emphasizes how the registry will become increasingly valuable for future studies of similar kind.

The principal disadvantage from which it was feared the Registry might suffer by its transfer from Boston to New Haven was its unavoidable separation from the voluminous and detailed clinical records which remain the property of

the Brigham Hospital. This disadvantage has been overcome by the recent reproduction, now completed, of the *circa* 50,000 pages of records that deal with this group of histologically verified tumors. Permission was given for this by the Brigham Hospital Board and through the co-operation of the Sterling Library at Yale the work was carried out with Leica camera and cinema-film methods, it having been one of the largest orders of the sort that has so far been completed. This puts in the hands of those, who will hereafter study the gross and histological preparations, the clinical records of the cases from which they have come, together with the subsequent correspondence and accounts of examinations which continue to be added to the case records as the years progress.

There is much still to be learned about brain tumors, many of which have not as yet even been satisfactorily classified, and only by continued study can the life history of one after another of the many varieties come, in the course of years, to be so fully worked out that the expectation for life and the relative freedom of the patient from incapacitation after operation of a given tumor can be known at the time it is first brought to view. Not until the life history of every kind of tumor is understood by the person who attempts surgically to deal with them can the lowest operative mortality and at the same time the longest survival period be obtained—a survival with the least impairment of the afflicted individual's intellectual and physical capacity to earn his livelihood.

Mr. Cairns' paper represents a new approach to the study of surgical end-results which is particularly important in the case of cerebral lesions. Surgeons heretofore have been satisfied to work out the operative mortality percentages with the survival periods for tumors of special kinds, but to try to determine after a given period what the survivors had been good for, and to what degree the spared life had been worth living is something altogether new in the field. Such a study would be possible only when records are of the best and when the relation of patients and doctors has been on an unusually intimate basis and patients are sufficiently grateful to allow the doctor to keep in touch with them up to the end.

In his prefatory note to Mr. Cairns' paper Dr. Cushing refers to certain matters which might be regarded as controversial. One of them no doubt was the question of how far outside discrimination and selection of cases might affect a surgeon's mortality percentages and survival periods. Dr. Cushing would probably be the first to acknowledge that his known interest in pituitary disorders led patients with adenomas to frequent his clinic, doubtless on the family doctor's advice, but beyond this it is difficult to believe that there was any discrimination

*Cairns H. W. B. The ultimate results of operation for intracranial tumors: a study of a series of cases after a nine-year interval. *Yale J Biol & Med* 8:421 (May) 1936

made in the type of cases recommended to the Brigham clinic for diagnosis and treatment. Certainly those who worked there know that no discrimination was made between favorable and unfavorable cases after the patients once arrived. It was most unusual for the neurologists, ophthalmologists or physicians who referred patients to do more than make a tentative localizing diagnosis except naturally enough in the case of acoustic tumors, in which the localizing diagnosis usually indicated the nature of the tumor as well.

It should be remembered also that before 1920 no attempt was made to distinguish between different types of gliomas either before or after operation. Until tumors were classified and the life history of some of them worked out, there was no possibility of discriminating before operation between favorable and unfavorable cases. It was felt that every case of intracranial tumor called for an operation and some still believe in following this rule today even in the case of the highly malignant cerebral glioblastoma multiforme and the cerebellar medulloblastoma.

The illuminating "longest known survival" figures which Dr. Eisenhardt has added to Mr. Cairns' Tables showing a four year survival for a glioblastoma and a seven year + survival for a medulloblastoma lead one to feel that in view of the surgeon's inability to make an absolutely correct preoperative pathological diagnosis he is scarcely justified in refusing operation because a tumor is presumably malignant and its surgical exposure is known to have a high percentage of early fatalities.

Mr. Cairns frankly admits his having mistaken a meningioma for a glioblastoma, which shows the risk of refusing to operate upon a presumptive tumor of this sort. The risk of similarly mistaking a benign cerebellar tumor for a medulloblastoma would seem to be too great to justify the preliminary radiation which some have advocated particularly in view of the fact that the survival period of a surgically treated astrocytoma for example may exceed twenty five years.

\$3 000 000 FOR THE MEMORIAL HOSPITAL OF NEW YORK

ANNOUNCEMENT has recently been made of this gift by the General Education Board founded by John D. Rockefeller of \$3 000 000 to the Memorial Hospital for the Treatment of Cancer and Allied Diseases. This munificent gift will allow the oldest cancer institute in the United States to build a new modern hospital and laboratory building on a new site adjacent to the Rockefeller Institute and the New York Hospital-Cornell Medical Center. It will also make available large funds for research. This

hospital has a long and honorable history and especially in the last twenty five years, under the leadership of James Ewing has become one of the great cancer institutes of the world. With this change of location to the proximity of the older institutions with which it has long been associated we may expect it to go on to a future of even greater triumphs than in the past.

Cancer research has been aided by many new gifts in the last few years and the results of this support are appearing almost daily. The treatment of cancer patients is improving by leaps and bounds all over the world and at last in some communities such as Massachusetts, the death records have begun to show this improvement. Even more striking however, is the accumulation of important new scientific knowledge of the nature of cancer and of the processes that lead to it. In New England we have many earnest groups of skilled workers devoting their time to this disease. We take this opportunity to salute Dr. Ewing and his colleagues on their being the recipients of this gift and to congratulate the General Education Board on the selection of the institute to which they have given it.

THE NOISE MENACE

CIVILIZATION may eventually decide that it *can get along without noise, and will then find that it can get along much better without it than with it.* At least it is encouraging to know that earnest efforts are being made in the direction of noise abatement even if a long course of public education will be necessary before any spectacular progress is made.

In New York a symposium on the effect of noise in health and disease was held recently at the Academy of Medicine under the joint auspices of the Medical Society of the County of New York and the City's Noise Abatement Commission. To know that a medical society might be interested in noise abatement is not surprising, to learn that politicians are in favor of less noise is news, and is encouraging.

Experiments at Bellevue Hospital were reported by Dr. Foster Kennedy of Cornell who had demonstrated that the noise resulting from the explosion of a paper bag raised the brain pressure to four times normal for seven seconds and that thirty seconds elapsed before the pressure returned completely to normal. Trephined patients were used for these experiments, the pressure being measured directly from the brain surface. The undoubted effect of constant noise, according to Dr. Kennedy, is disturbance of the blood vessel apparatus, and the increase in the degenerative processes in the heart and arteries.

Further experiments have shown that a difference of 19 per cent in energy expenditure

Hicks' version, followed by spontaneous delivery offers the best prognosis for the mother while if less than two fingers the insertion of a Vorhees' bag, followed by J. Braxton Hicks' version and delivery as above has given excellent results. Removal of the bag at two or three fingers' dilatation is preferable to waiting for its spontaneous expulsion as the latter is apt to be followed by an immediate hemorrhage. At tempt at extraction before full dilatation is a dangerous procedure.

It is significant that the morbidity in placenta praevia is appreciably higher than in normal pregnancy and that mortality from sepsis is as much to be feared as deaths from hemorrhage hence strict asepsis with the more frequent employment of hysterectomy especially in potentially infected multiparae, is an important consideration.

THIRD ANNUAL POSTGRADUATE MEDICAL EXTENSION COURSE

The following sessions have been arranged by the Committee for the week beginning May 24

Berkshire

Thursday May 28 at 4 30 P.M. at the House of Mercy Hospital Pittsfield Subject: Pediatrics (Surgical)—Abdominal Disease in Childhood. Instructor: P. J. Mahoney, M.D. Melvin H. Walker, Jr., Chairman.

Middlesex East

Wednesday May 27 at 4 00 P.M. at the Melrose Hospital Melrose Subject: Pediatrics—Abdominal Disease in Childhood. Medical and Surgical Aspects. Instructors: P. H. Sylvester and H. W. Hudson, Jr. Joseph H. Fay, Chairman.

Norfolk

Friday May 29 at 8 30 P.M. at the Norwood Hospital Norwood Subject: Ophthalmology and Otolaryngology—(a) The Major Hazards in Diagnosis of Diseases of the Eye, Ear, Nose and Throat as Seen in General Practice. (b) Special Treatment in Acute Medical and Traumatic Diseases of the Eye. Emergencies Arising in the Treatment of the Ear, Nose and Throat. Instructors: P. A. Chandler and C. T. Porter. H. B. C. Riemer, Chairman.

Worcester (Milford Section)

Wednesday May 27 at 8 30 P.M. at the Milford Hospital Milford Subject: Syphilis and Gonorrhea—Syphilis: Modern Treatment. The Use of Neosalvarsan, Tryparsamide, Bismuth, Mercury, Potassium Iodide, etc., in Office Practice. Gonorrhea: Treatment of Complications as Seen in General Practice. Instructors: A. W. Cheever and N. A. Nelson. Joseph I. Ashkins, Sub-Chairman.

REPORT ON THE ACTIVITIES OF THE PUBLIC RELATIONS COMMITTEE OF THE MASSACHUSETTS MEDICAL SOCIETY SINCE THE LAST COUNCIL MEETING

SECTION FOR SCHOOL PHYSICIANS

At the last Council meeting a petition for the establishment of a section for school physicians was referred to this committee for recommendations. The committee carefully considered sections already in existence, pediatrics, etc., and also considered needs for other sections and recommends that no action be taken at this time.

THE WASHINGTON PLAN

Under the sponsorship of the Massachusetts Medical Society, the Massachusetts Dental Society and the Boston Hospital Council, Mr. Ross Garrett, coordinator of the Washington (D. C.) Plan for Medical Care, addressed a special meeting to which Councilors were invited held at the Medical Library, February 18, 1936. The Public Relations Committee is sufficiently impressed with the value of this plan to feel that it is worth while in the near future to send two representatives to Washington to make first hand studies with the view to determine if this plan with some modifications can be used to good advantage in some sections of Massachusetts.

PROPAGANDA ON COMPULSORY SICKNESS INSURANCE

The Subcommittee on Social Legislation and Insurance (Dr. M. A. Tighe) is continuing public education regarding Compulsory Sickness Insurance. Further radio broadcasts will be continued in the fall.

SURVEY ON ADEQUACY OF MEDICAL CARE

The Subcommittee on the Adequacy of Medical Care (Dr. E. L. Hunt) has been making family studies principally in Worcester County but also in other sections. The studies are still being continued and final conclusions and recommendations will be presented at a later meeting. The Public Relations Committee believes however that the following recommendations should be adopted at this time:

Recommendations of the Subcommittee on Adequacy of Medical Care

The results of our studies set forth in accompanying reports have revealed inadequacies of various types. By far the greatest obstacles which lie between the population in general and the best in medical care are the results of causes deeply rooted in human nature itself in our social structure in the inadequacy of our laws governing the licensure of physicians in medical education even in medical science itself. In lack of intelligence and initiative on the part of the people who need the care in overlapping and competing agencies of medical service in parasitic cults and commercialized medical products.

Other obstacles are more superficial and more readily adjustable by comprehensive planning and

more diligent effort. Of these, uneven distribution of medical facilities and practitioners, lack of information and understanding of their health needs by the people, and the economic barrier are susceptible of improvement by organized effort and better planning.

In order to initiate such effort in harmony with our pledge to find remedies for such inadequacies as our studies should uncover (Council vote April 4, 1935) we recommend

I. That each district society be urged to form within its area, Health Councils composed of carefully chosen representatives of the Welfare Agencies, Hospital Boards, health and welfare departments, and nursing and dental societies. The functions of these Councils to be

- 1 Education of the public in the needs and possibilities of medical service, preventive as well as curative, and in the ways available for securing it
- 2 Making provision for suitable clinics or district visiting services where need is found (rural and factory village areas)
- 3 Securing co-operation in its program from industrial, fraternal, social and health organizations
- 4 Establishing welfare department responsibility for and intelligent administration of medical care for the indigent and near-indigent in each town and city by
 - a Employing the licensed physicians of the community at reasonable pro rata fees
 - b Subsidizing licensed practitioners to locate where there are no physicians in residence
- 5 Influencing established hospitals to broaden their function so as to serve as health centers in co-operation with local health departments and as welfare centers in co-operation with local welfare departments
- 6 Promulgating, locally organizing and thereafter serving as an advisory body in the administration of any programs of voluntary insurance for hospitalization and medical care which may receive the approval of the State Society

II That a State Health Council of similar constitution be developed whose functions shall be to co-ordinate the work of the local Councils, advise as to methods, study legal relations and devise enabling statutes when necessary to simplify procedures and increase efficiency in carrying out the primary purpose of promoting better health by bringing adequate medical care to the people and relieving economic distresses which are detrimental thereto

PREPAID HOSPITAL INSURANCE

The Public Relations Committee held a joint meeting with the committee of the Boston Hospital Council on April 1 to discuss Prepaid Hospital Insurance. Dr. Faxon explained the proposed program and definitely stated that the Plan would not be initiated without the endorsement of the Massachusetts Medical Society. The discussion was free and frank and criticisms by our committee were accepted and embodied in the revision of the Plan. The revised Plan has the unanimous endorsement of the Public Relations Committee and its adoption by the Council in principle is recommended. The matter was then referred to the Subcommittee on Hospital Relations (Dr. J. Harper Blaisdell) for study and modification. The result of the mutual conference by Dr. Blaisdell's committee and the committee from the Boston Hospital Council is appended below for your careful consideration.

FREE CHOICE OF PHYSICIANS UNDER WORKMEN'S COMPENSATION ACT

The Subcommittee on Hospital Relations also obtained a legal opinion on the subject of free choice of physician under the Workmen's Compensation Act which is appended below. The committee herewith asks authorization to employ counsel at the expense of the Massachusetts Medical Society to carry a test case to the Supreme Court if and when a suitable test case arises. The committee earnestly requests attention of all Fellows to this matter so that a test case will adequately cover the points in doubt.

PREPAYMENT HOSPITALIZATION PLANS

Prepayment Hospitalization Plans essentially provide a mechanism by which a group of people may insure against hospital costs. This mechanism is called a Hospital Service Corporation. It is a non profit corporation, set up under State laws. It makes contracts with subscribers agreeing to pay within specified limitations, their hospital bills. In order to fulfill these contracts it arranges with hospitals to provide service when needed by subscribers, paying these hospitals for all service rendered, at specified rates.

Certain essential principles must be understood and adhered to

1 Such plans are primarily intended to enable subscribers to budget hospital bills, rather than to provide revenue for hospitals

2 At least a majority of the hospitals of a community must be included in the plan so as to provide a free choice of hospitals, such as now exists

3 It must be nonprofit and controlled by persons more interested in the quality of service rendered than the low cost of such service. Representative groups in the community should sponsor and control hospital service plans rather than private investors who are primarily concerned with private gain

4 It must not interfere in the existing relationship of patient, doctor and hospital

5 It must follow sound actuarial principles as to subscription rates, scope of benefits, and payments to hospitals

Prepayment plans are founded upon the fact that although sickness requiring hospitalization in a group of 1,000 persons cannot be predicted as applying to any individual in the group, nor if hospitalized the length of such hospitalization, the total number of persons who will require hospitalization

and the total number of days of hospitalization for the group can be accurately estimated. If then the total cost of hospitalization is equally divided among the group the amount paid by each subscriber will be small. Roughly speaking, 1,000 persons will require 1,000 hospital days which can be provided at a cost of approximately \$10.80 per year per subscriber. Similar use of this principle of insurance has been successfully used in Fire, Life and other forms of Insurance.

Present actuarial information limits subscribers to employed persons, employed because employment presupposes a certain degree of health and ability to meet such financial obligations as are contracted for.

Cooperative study by a Committee representing the Hospital Council of Boston and the Subcommittee on Hospitals of the Committee on Public Relations of the Massachusetts Medical Society has resulted in a plan having these essentials:

There shall be incorporated the Associated Hospital Service Corporation of Boston with a majority of Directors chosen from Trustees of Hospitals in the Metropolitan area, the remainder to be representatives of the Massachusetts Medical Society, the Community Federation, the Council of Social Agencies, the Chamber of Commerce and similar organizations. It shall be a nonprofit organization and no member of the corporation shall receive a salary.

The Hospital Service Corporation shall be empowered to make contracts with groups of employed subscribers for the provision of hospital care within certain limitations which will be clearly stated in the contract. The anticipated cost per year to each subscriber would be \$10.80. No geographical limitations other than State boundary will be set, *but in order to maintain existing relationships between patients, doctors and hospitals subscriptions can only be issued in communities where a majority of the hospitals in the community have entered into agreements with the Service Corporation for the provision of hospital care.*

The Hospital Service Corporation may also enter into contracts with any hospital authorized under the laws of Massachusetts for the provision of hospital care to subscribers at a fixed rate of payment for each day of service rendered. The anticipated payment for each hospital day is \$6.00. Hospital care shall be that type of care usually designated as semiprivate and all professional fees shall remain a matter of arrangement between patient and physician exactly as they do at present for such cases. Admission of patient shall be subject to the usual rules and regulations of the individual hospital and shall be only upon recommendation of a physician, excepting in case of emergency.

The general principle of Prepayment for Hospitalization was endorsed in 1933 by the American Hospital Association, subject to the limitations set forth above. At present there are over sixty communities in the United States with group hospital

zation plans which have enrolled over 300,000 subscribers and involve several hundred hospitals and which in some instances have been operative for five years.

Only the general outlines have been given here since it was felt that the inclusion of the details of contract with subscribers and the contracts with hospitals would only lead to a confusing discussion of these details rather than a consideration of the general principles involved that these details could safely be left to be worked out by the committees representing the Massachusetts Medical Society and the Boston Hospital Council.

WORKMEN'S COMPENSATION ACT (FREE CHOICE OF PHYSICIAN)

Your Committee has procured an opinion from counsel as to the right of a physician on the staff of a public or charitable hospital to obtain payment from the insurer under Section 30 of Chapter 152 of the General Laws (The Workmen's Compensation Act) for services rendered an industrial employee who has been brought to the hospital for treatment.

This Section 30 so far as material provides that during the first two weeks after the injury and in unusual cases or cases requiring specialized surgical treatment in the discretion of the department for a longer period the insurer is to furnish adequate and reasonable medical and hospital services that the employee may select his own physician and the reasonable cost of the services of a physician so selected or of a physician other than the one provided by the insurer and called in case of emergency or for other justifiable cause shall be paid by the insurer subject to the approval of the department.

The Industrial Accident Board has laid down the rule that an industrial case coming into the hospital as a hospital case, cannot be made into a private case in which the attending physician may collect from the insurance company for his services as in a private case.

ALLEN CASE

The first case decided by the Supreme Judicial Court passing upon the right of a physician to payment for his services under Section 30 was Allen's case 265 Mass. 490 decided in 1929.

In this case the fingers of the employee were jammed. He consulted a doctor who bandaged the hand and sent him to the hospital. At the hospital, a nurse asked him if he had a doctor and he said he knew no doctor at the hospital. Then the nurse suggested the name of Dr. Spellman and he said that Dr. Spellman would be all right.

The doctor was denied payment for his services on the ground that there was no selection by the employee within the meaning of the statute and no emergency existed. The Court further held that physicians as well as nurses are generally expected to be in attendance at a public hospital. A pa-

tient who has been taken to such an institution if he has no physician of his own to treat him, naturally expects that he will receive treatment from some one on the staff. When an employee under the compensation act goes to such a hospital and does not select a physician the payment to the hospital of its charges includes the expenses of nurses and physicians and the insurer is not required to pay the physician who is a member of the staff for his services.

ZOMHRIC CASE

In 1935 the Supreme Court handed down its decision in Zomhrics case 1935 A. S. 877.

In this case the employee's hair was caught in a revolving shaft and her scalp and the back of her neck were torn off. She was taken to the hospital and Dr. Blood, a member of the staff who was on call but not on duty was called to the hospital to treat her at about 7 A.M. She was of age. At noon of the same day Dr. Blood talked with the girl's father informing him that he could get any physician that he wished to treat her. The father told Dr. Blood to continue to treat her. A week after the accident Dr. Blood notified the insurer of the case and length of treatment necessary. The insurer answered the letter but did not expressly authorize him to continue. The girl never actually selected Dr. Blood but she acquiesced in his treating her for several months.

The Board approved the bill of Dr. Blood finding justifiable cause existed for his treatment of the employee as a private patient. Upon appeal by the insurer Dr. Blood was granted recovery on the grounds (1) that an emergency existed and (2) that there had been a selection by the father ratified and adopted by the employee the exact amount of such selection being immaterial. The Court reports it as sufficient that the treatment continued as that of a private patient although it did not begin as such.

The general principles laid down in these cases appear to be that a staff physician is entitled to reasonable compensation for his services from the insurer when he treats an employee in the hospital (1) in an emergency (2) for other justifiable cause or (3) after selection by the employer.

The difficulty in obtaining such compensation however arises in view of the present attitude of the Board from the fact that the Board must pass on these questions in the first instance, and that an appeal from an adverse finding of the Board to the Courts may be taken only on questions of law since the Board's finding of facts is final and conclusive. It should further be noted that the physician is protected by the statute only for the first two weeks after the accident, except in unusual cases or cases requiring specialized or surgical treatment the existence of which must be found by the Board as a fact.

As to the right of the staff physician to obtain compensation for his services must depend upon the

facts of each case, it is impossible to lay down any procedure that will absolutely assure him of compensation. However, your Committee makes the following suggestions that should prove of assistance to the employee in choosing his own physician, if he desires, and to the staff physician in procuring compensation for his services, if he is selected by the employee to attend him.

1 All industrial accident employees should be treated in private or semiprivate rooms or wards. This is in accordance with our previous recommendation as set forth in the report of the Public Relations Committee of the Massachusetts Medical Society presented at the Council Meeting, June 5, 1934.

2 As soon as the condition of the employee warrants his being questioned, the name of his regular family physician, if any, should be ascertained. If he has such a physician who is on the staff or courtesy staff of the hospital, his physician should be notified immediately and called in to treat the employee. In cases where surgical or unusual treatment may be required, the employee may make his selection with the assistance of his family physician.

If the employee has no regular family physician, he should be advised of his right of selection under the law, *including the right to select a staff physician, if he desires*, as soon as he is completely able to understand his situation, with mind unclouded by pain, drugs, or the effects of the accident, and should be told that such selection need not be made until he feels disposed to make it. Any question of the employee's capacity to make the selection may invalidate it, and hence the employee should be encouraged to defer the selection until his condition clearly warrants his making it.

We suggest that some one in authority in the hospital, other than the physician or nurse in attendance, should handle this matter. The utmost good faith should be exercised by all who come in contact with the employee. Under the decisions, no suggestions should be made to him by any one in the hospital as to the physician to be selected. The employee can be told the names of all the physicians on the staff from whom his selection may be made if he desires to select one, but the choice must be left entirely to him. The likelihood may well be that he will select the physician who has been treating him. If the patient is a minor, the selection may be made by the parent or guardian.

3 A written record should be kept for evidential purposes of the conversation of the parties at the time of instructing the employee of his right of selection and at the time such selection is made. The logical place for making such a record would be in the patient's hospital record. Although it would be most desirable to have a record of the entire conversation or conversations, it would be impractical,

if not impossible, to make such a record in many cases. Such a record will be very important in the event of a case arising before the Board in which testimony on this subject may need to be given. Therefore, in all cases in which the entire conversation cannot be recorded, a record should be kept which will be sufficient to enable the party making it to refresh his recollection for purposes of testifying in any proceeding. Although it is impossible to lay down any definite rule as to the extent of the record to be made in each case, it should contain at least the following:

- "a. A brief statement of the employee's physical and mental condition
- b. Employee stated Dr _____ was his regular family physician
- c. Dr _____ called in to treat him"

In cases where the employee has no such physician or the physician is not on the staff or courtesy staff of the hospital, the record should contain the following:

- "a. A brief statement of the employee's physical and mental condition
- b. The employee stated that he had no regular family physician or the physician was not on the staff or the courtesy staff of the hospital as the case might be
- c. Informed employee of his right of selection which he might exercise if he desired
- d. Employee expressed a desire to select a physician
- e. Informed employee that he could select any one of the following physicians (list names)
- f. Employee selected Dr _____ to treat him"

All such records should be dated and signed by the party making them.

Your Committee is desirous of doing everything possible to assist the members of the Society in this situation. However, it would be impractical, if not impossible, for the Society to arrange for representation by counsel at all hearings before the Board in which this question is involved.

Your Committee's part in the matter must be limited to furnishing you with assistance in bringing before the courts those cases in which an appeal from an adverse decision of the Board seems warranted. In order to take an appeal under the law, a copy of the record must be procured from the Board and entered in the Superior Court *within ten days* after notice of the filing of the Board's decision.

Therefore, if you have a case which comes within the foregoing suggestions we wish that, in the event of an adverse decision, you would mail promptly the copy of the decision to Dr J. Harper Blaisdell, Chairman of the Sub Committee on Hospitalization, 45 Bay State Road, Boston, Mass.

At the Springfield meeting of the State Society in June, the officers of the Boston Medical Library will gladly welcome all who are already interested in the work of the Library and any who are so conscious of the truth expressed by the following quotation that they are inspired to perfect themselves by further study

For never yet hath any one attained to such perfection but that time and place and use have brought addition to his knowledge or made correction or admonished him that he was ignorant of much which he had thought he knew or led him to reject what he had once esteemed of highest price"

One or more of the Library Committee will be in attendance prepared to explain such services as the Library is in position to render. The Booth allotted is No. 6 in the Springfield Municipal Auditorium.

"American Book Prices Current." N. Y. 1936

The above selections have been made by the Library Committee after consultation with representatives of various Societies of specialists and from the recent offerings of publishers who have submitted their new books for inspection by the Committee at fortnightly intervals.

There follow a few abstracts offered by individuals engaged in preparing the various Progress reports which appear from time to time in *The New England Journal of Medicine*. It is impossible of course to do more than single out a few each quarter and the effort has been to select the few that do appear because of their outstanding practical value to general practitioners.

ALLERGY

Perhaps nothing has given rise to more confusion than the word allergy. No two men seem to use it in quite the same way. To one man it seems to mean a sensitivity to some certain substance. To

From Progress in Diseases of the Skin

another it seems to mean every disturbance in sensitivity of any sort whatever. To many others it seems to mean nothing definite but only that if they use the word, even without sense, they are keeping up with the times.

Sulzberger and Goodman¹ think that the confusion which naturally has arisen from such loose use would be eliminated if writers would adhere strictly to the definition of allergy made by von Pirquet and Schick in 1906 to the effect that it denotes an altered state of reactivity in an individual (human or animal). A little farther on in the same paper they give the application wide scope saying that "all the allergic reactions mentioned above can occur in all organs, in any organ, in any part of an organ and in any system," which means that allergy includes about everything, if not indeed everything, which only a few years ago was explained on the ground of intoxication, auto-intoxication, sensitivity, hypersensitivity and susceptibility. Such cases would now, in modern terminology, be called allergic or allergy.

One is enabled to understand this point of view better by reading an earlier article by Sulzberger, Wise and Wolf.²

Unfortunately, the position taken by Sulzberger and his collaborators does not clear up everything as Grow and Herman's paper³ proves.

Grow and Herman report that out of 150 so-called normal individuals 55.5 per cent reacted positively to 1 or more of 13 test extracts used. 4 reacted to all the extracts and 1 control was positive.

These figures suggest that Sulzberger and Goodman's criteria of allergy are far more accurate. According to Grow and Herman—family history, personal history and intracutaneous tests are as common in normal individuals as in "allergic." Indeed, the latter conclude, without confirmation by the history and the clinical manifestations, they are but aids to diagnosis and even positive tests are not necessarily proof of allergic disease.

ANESTHESIA*

The January number of *Annals of Surgery*, volume 103, contains five articles of particular interest to anesthesiologists.

These are the following:

- 1 Page 13 The Surgical Risk, Rodman J S and Leaman, W G, Philadelphia.
- 2 Page 24 The Renal Phase of Surgical Risk, Rowntree L G, Philadelphia.
- 3 Page 29 Pantocaine in Spinal Anesthesia, Bull, D C and Esselstyn, C B, New York.

4 Page 38 Carbon Dioxide Absorption Technique in Anesthesia, Waters, R. M., Madison.

5 Page 46 Preanesthesia Narcosis with Paraldehyde, Henderson, J, New York.

- 1 Rodman evaluates chiefly the cardiac risk. "We have advanced considerably since the days when a stethoscope to the chest in the anesthetizing room was considered sufficient to determine the risk of the patient from the cardiac standpoint. The features then of a complete heart study before operation consist of an inquiry into the patient's symptoms to determine myocardial function, a survey of the patient's past medical history to search out diseases which are known to affect the heart, a record of all the physical signs elicited and, if possible, fluoroscopic and electrocardiographic examinations to complete the picture." We often speak of the stress and strain of the operation on the heart, yet this is hardly greater than the work the heart does during the normal activities of any day. The symptoms that are commonly recorded as cardiac arise, in many instances, from other causes. When we see the skillful anesthetist take patients through long operations with no change in the heart rate, mechanism of the heart beat and with little or no change in the blood pressure and no visible venous engorgement, we realize the importance of choosing the anesthetist and the part the anesthetist has in making the burden borne by the heart indeed a light one.
- A heart which carries its daily burden well without excessive dyspnea or chest pain is equivalent to the normal organ."

- 4 Waters describes the historical basis for the foundation of modern anesthesia, with special note of progress as he has seen it.

"In the year 1916, the following conditions obtained in regard to inhalation anesthesia:

- 1 A completely open technic was known to result in a cold dry atmosphere being inhaled, resulting in irritation of membranes and resultant hyperactive breathing.
- 2 A semiclosed technic was as a rule less damaging to the patient but required much clinical judgment in its use. Respiratory movements were excessive due to retained carbon dioxide. Cost of gas anesthesia, though less than with completely open technic, was for many cases prohibitive.
- 3 With all inhalation anesthesia, sweating was the rule, reduction of body temperature usual, annoyingly hyperactive breathing frequent, and operating teams were constantly exposed to high concentrations of agents used." The advantages of the carbon dioxide absorption technic are demonstrated.

*From *Progress in Anesthesia*

5 Henderson's usual dose of paraldehyde is .15 cc. per pound of body weight given in a vehicle of starch solution, 2 table-spoonfuls to the pint but rarely exceeding 5 ounces in total volume. This is given 1½ hours preoperatively by rectum. One-half hour preoperatively 1/6 gr morphia and 1/150 gr atropine or scopolamine is given hypodermically. Either nitrous oxide or ethylene is the usual inhalation anesthetic. In his series there have been emnesia marked lessening of the amounts of gases used, comfort, and safety. Paraldehyde is cheap, requires no special preparation and is easily administered by the nurses. He states that the smell is not objectionable.

BOOK REVIEWS

Prospective purchasers of medical books are not infrequently the victims of high pressure salesmanship on the part of agents who visit at inopportune times. Many books are bought under such circumstances that are really not the best for the individual's needs. *The New England Journal of Medicine* presents in its 'Book Review' department a means of checking up on the worth while books. Attention is called below to reviews of a few of the more recent publications about which some may desire information and reference to this department in *The New England Journal of Medicine* will simplify the process of securing for one's own library the texts one should possess.

The Theory and Practice of Anaesthesia by M. D. Nosworthy published in London and reviewed quite fully in *The New England Journal of Medicine* (March 5 1936 p 500) and a review of five recent articles in the *Annals of Surgery* given above will be found a very practical help to practitioners and students as well as to professional anesthetists.

A biographical sketch of one of America's foremost obstetricians John Whitridge Williams former Professor of Obstetrics at the Johns Hopkins University Hospital and Medical School is well recommended in a review on p 500 of *The New England Journal of Medicine*'s issue of March 5 1936.

Dr. James Peter Warhase's volume on "The Doctor and the Public," reviewed in the issue of February 10 1936 of *The New England Journal of Medicine* on p 400 cites the study of the present day social aspects of physicians' relations with the public. Also under date of February 20 p 400 appears an appreciation of the recently published small volume of the "Diagnosis and Treatment of Pulmonary Tuberculosis" by Drs. John B. Hawes and Moses J. Stone.

Volume III of the Forty-Fifth Series of the International Clinics, edited by Louis Hamman, is one of its significant articles are appraised in a review appearing on p 400 of *The New England Journal of Medicine* for February 20 1936.

RULES GOVERNING THE USE OF THE LIBRARY

Hours: During the months of October to June inclusive the Library will be open daily except Satur-

days. Sundays and Holidays from 9 30 A.M. to 6 P.M. Saturdays the Library will close at 5 P.M. From October 15 to May 31 the Library will be open Monday and Wednesday evenings from 6 to 10 o'clock. During July, August and September the Library will close daily at 5 P.M., except Saturdays, when it will close at 12 noon.

Most books and periodicals may be borrowed for periods varying from three to fourteen days.

MISCELLANY

THE PRESIDENT ELECT AND THE VICE-PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION

At the Annual Meeting in Kansas City Dr. John H. J. Upham of 244 N. Parkview Avenue, Columbus, Ohio, whose office is at 527 East State Street, was elected President Elect of the American Medical Association and Dr. Charles Gordon Heyd of New York City was elected Vice-President.

Dr. Upham was born in 1871 and graduated from the University of Pennsylvania Medical School in 1894. He is Chairman of the Board of Trustees of the American Medical Association and Dean and Professor of Medicine of the Ohio State University College of Medicine.

Dr. Heyd was born in 1884 and received his M.D. degree from the University of Buffalo School of Medicine in 1909. He is Professor of Clinical Surgery at Columbia University and Director of Surgery and Attending Surgeon at the New York Postgraduate Hospital and Dispensary. He holds the position of consulting surgeon to several other hospitals.

His office is at 115 East 53rd Street, New York City.

APPROVED PROPHYLACTIC REMEDY FOR USE IN THE EYES OF INFANTS AT BIRTH

The Massachusetts Department of Public Health in accordance with the provisions of Chapter 115 of the Acts of 1936 approves the following "prophylactic remedy" for the treatment of the eyes of infants at birth. A one per cent filtered solution of silver nitrate U.S.P. in distilled water stored in ampoules for single use; the ampoules to be protected against penetration of light and provided that if the ampoule must be broken it shall not be made of glass or other shatterable material which might cause injury to the eye and further provided that the ampoule or its container shall bear an expiration date which shall not be later than six months after the date of preparation of the solution and that no solution shall be used after said date of expiration.

Under the provisions of Chapter 115 of the Acts of 1936 no prophylactic remedy may be used after June 4 1936 for the treatment of the eyes of infants at birth which is not furnished or approved by the Department of Public Health.

The Department recommends the following pro-

cedure for the protection of an infant's eyes against infection at birth

- 1 Every pregnant woman, concerning whom there is the least suspicion of gonococcal infection, should be so treated for the infection, both during pregnancy and at delivery, that the birth canal may be as free as possible from the gonococcus during the birth of the baby
- 2 The following order of procedure is recommended for the use of the prophylactic in the baby's eyes
 - a Clean the skin of the four eyelids with cotton pledgets moistened in boric acid solution, using separate pledgets for each eye
 - b Thoroughly irrigate the conjunctival sac of each eye with boric acid solution, using a sterile soft rubber ear syringe
 - c Retract the eyelids, digitally, and instill one drop of a one per cent solution of silver nitrate into each eye, preferably near the outer canthus, and allow the solution to remain in contact with the conjunctiva for at least two minutes
 - d Irrigate the conjunctival sac of each eye with sterile normal salt solution to prevent chemical conjunctivitis
 - e Secure the services of an ophthalmologist upon the first appearance of suppurative conjunctivitis and insist upon a bacteriological report on the conjunctival secretions
- 3 Precautions
Since corneal abrasions promote ulceration in the presence of the gonococcus, great care must be taken to avoid contact between the cornea and the finger manipulating the eyelids, the irrigating syringe or the eye dropper, if the above recommended procedure is carried out

HENRY D CHADWICK, M D,
Commissioner of Public Health

May 12, 1936

THE AWARD TO DR E R BALDWIN

On May 6, 1936, Dr E R Baldwin of Saranac Lake, New York, was awarded the Dr George M Kober Medal by the Association of American Physicians, at its annual meeting, in recognition of his research work in tuberculosis

This award is given annually in honor of the late Dr Kober, former professor of medicine and Dean at George Washington University

CONNECTICUT NEWS ITEMS

Dr R. L. Leak, Superintendent of the State Hospital for the Insane at Middletown, recently appeared before the State Board of Finance and Control asking for some relief of the overcrowding existing in his institution. The hospital now has 600 ward employees, sixteen of whom are physicians, one physician to 170 patients. Through Dr Leak the trustees

asked for two more physicians as well as additional ward attendants. The board immediately authorized the trustees to add one senior physician and twenty five ward attendants. It is recognized that this project by no means solves the problem of over crowding at the hospital but it is, nevertheless, a step in the right direction

Dr Robert V Boyce, president of the Hartford Board of Health, was named acting health officer of the city at a special meeting of the commission on May 1, 1936. At the same time the board gave Dr Thomas F O'Brien, who has been acting health officer, an indefinite leave of absence with pay because of illness. Dr Boyce's basic salary was set at \$5,000, an increase of \$1,000 over that of his predecessor

The Litchfield County Medical Association held its annual meeting at the Charlotte Hungerford Hospital, Torrington, Tuesday afternoon, April 28, 1936

The following officers were elected

President Maurice J Reidy, M D, Winsted
Vice-President Howard Allen, M D, Woodbury
Secretary-Treasurer W Bradford Walker, M D, Cornwall
Councillor Harry B Hanchett, M D, Torrington
Censor Roy Sanderson, M D, Winsted
Chairman, Committee on Public Policy and Legislation Sanford H Wadhams, M D, Torrington
Chairman, Committee on Medical Ethics and Department Harry B Hanchett, M D, Torrington
Chairman, Medical Economics Committee Timothy M Ryan, M D, Torrington

As guest speakers the Association listened to Walter Dannreuther, M D, New York Post-Graduate Hospital, and to Walter R Steiner, M D Douglas J Roberts, M D, and Wilmar M Allen M D, of Hartford

Dr Albert W Buck Superintendent of the New Haven Hospital and President of the Connecticut Association of General Hospitals, appeared recently before the Commission to Study the Pauper Laws. He informed the Commission that the general hospitals of Connecticut are contributing thousands of dollars a year in the care of state patients for which they are never fully reimbursed by the State. Dr Buck characterized relief cases as a serious financial problem

The State now pays each general hospital a flat yearly appropriation and in addition four dollars per week for each state case. Hospitals caring for a large number of state patients find this compensation far below the actual cost of the care of these patients. The four dollar weekly rate was established thirty years ago when the average cost of hospital care was six dollars per week. Now the average cost is thirty five dollars per week per patient.

It was brought out in the discussion that the Hartford Hospital has lost \$160,000 in the last five years in caring for the state cases and St Francis

Hospital \$43 000 in the last year. The Assistant Superintendent of the Hartford Hospital informed the Commission that the flat appropriations are given out on a political basis and some hospitals with very little charity work receive the same grants as hospitals with a large number of these patients. He also stated that the last adjustment of the grants was made in 1921 and since then the amount of care given state cases has increased materially. The whole amount of free service given by the hospitals in Hartford has risen 160 per cent in three years. At the same time the private gifts to hospitals have dropped to one-fourth the amount in 1929.

Another fact of interest was revealed at this hearing, viz. that old age assistance ceases the moment the beneficiary enters a hospital. That person then becomes a town or city charge.

Specimens of marihuana, also known as Indian hemp and as hashish are being grown in the laboratories of the State Health Department in New Haven. It is planned in about a month to distribute these to fifty police stations throughout Connecticut so that marihuana may be recognized when growing and ordered by the police to be instantly uprooted. This weed grows wild in Connecticut and has been found within the limits of Hartford. Fearing the perversion of youth by its usage the Narcotics Division of the State Department of Health is concentrating every effort to stamp it out. It is easily obtained and commonly used by drying the leaves and smoking them in cigarettes.

It is a known fact that marihuana sometimes gives man the lust to kill unreasonably and without motive. Many cases of assault, rape, robbery and murder are traced to the use of this weed.

The police have found traffic in marihuana cigarettes going on in Hartford, the product being imported from New York. They also are of the opinion that the weed is being grown in the city, the exact location not yet having been discovered.

Dr James A. Greenway, Director of the Department of University Health at Yale since its establishment in 1916, will retire in June. He will be succeeded by his assistant, Dr Orville F. Rogers. The department is considered a pioneer in its field. Twenty years ago when it was established 497 students applied for advice and assistance. Last year the department recorded 34 100 consultations.

Dr Greenway graduated from Yale in 1900. He received his medical degree from the College of Physicians and Surgeons of Columbia University and served as associate attending physician at the New York Hospital and as attending physician at the Seton Hospital before returning to Yale. During the World War he was a major in the U S Army Medical Corps. Dr Rogers has been associated with the University Health Department since its organization and has been assistant director since 1921. He is a graduate of Harvard.

Connecticut will have membership on two of the four committees appointed by Secretary Perkins of the Federal Labor Department in a concentrated drive being carried on against silicosis. Warren A. Cook of the Connecticut Department of Health has been appointed chairman of the committee on the prevention of silicosis through engineering control and Dr Stanley H. Osborn, State Commissioner of Health has been appointed a member of the committee on regulatory and administrative phases of the silicosis problem. Such valuable members of these committees should be of real aid in handling this problem of preventive medicine.

The diphtheria situation in Hartford has shown a striking change. In 1883 with a population of 43 000 there were 234 child deaths from diphtheria. In 1935 but one child died of this disease. In 1884 there were 122 child deaths from diphtheria and from that year to 1889 between twenty five and fifty died each year from this cause. In 1889 occurred an epidemic when 118 lives were lost.

This year Hartford is carrying on its annual campaign to inoculate preschool children. Clinics for the purpose are being set up throughout the city.

The Connecticut Public Health Association held its annual meeting May 6 1936 in Hartford. More than seventy five city and state officials attended. Dr Stanley H. Osborn, State Commissioner of Health, was among the speakers. He stated that federal funds allocated to Connecticut for various phases of health work are used exclusively where it is known they will be effective. Money sent into the state from the Public Health Service and the Children's Bureau at Washington is distributed locally wherever it is requested and in such places that the town set up complies with the federal requirements. The State has about \$40 000 waiting to be allocated to towns that ask for it. Most of the money is being spent in rural areas and no effort is being made by the State Department of Health to push the program where it is not wanted.

The subject of Public Health and the Social Security Act" was discussed at the morning session by Dr C O Applewhite, surgeon, regional consultant, U S Public Health Service; Dr Doris Murray, regional consultant, U S Children's Bureau; Dr B O Horning, director local health administrator, State Department of Health; and Dr Joseph I. Linde, Chairman, public health advisory committee, Connecticut State Medical Society.

Following luncheon and a business meeting, Elizabeth Taylor, R.N., director Bureau of Public Health Nursing, State Department of Health, spoke on "What the Community Expects of the Public Health Nurse." Dr B B Robbins, health officer of Bristol and president of the Association, spoke briefly on current problems confronting health officers. Dr Louis J. Dumont, health officer of New Britain, led the discussion.

AN HONOR TO DR FAXON

A merited tribute was paid to Dr William O Faxon of Stoughton at a dinner at the Hotel Lenox, Boston May 1, in celebration of his sixty years of practice. Although Dr Faxon has seen eighty-two birthdays, he is still active and has served Norfolk County as medical examiner for forty-two years.

In addition to the social features of the occasion, a silver platter bearing the engraved names of those who were privileged to participate in this celebration was presented to Dr Faxon.

Dr Faxon's son, Dr N W Faxon, is the Director of the Massachusetts General Hospital and is known as an able administrator of hospital problems.

TWO FORTUNATE HOSPITALS

Under the terms of the will of Ozro M Field of Beverly filed in the probate court the residuum of his estate above one hundred thousand dollars is to be distributed, after the death of his widow, equally to the Palmer Memorial Unit of the New England Deaconess Hospital, Boston, and the Beverly Hospital, Beverly.

The report gives no inventory of the estate, but the testator was characterized as wealthy.

Both hospitals are worthy of the confidence shown by Mr Field and will administer the trust wisely. Very many hospitals should be remembered by persons who are making wills.

THE AWARD OF THE TRUDEAU MEDAL

The Trudeau Medal of the National Tuberculosis Association has been awarded to Dr Edward W Archibald, professor of surgery at McGill University and consulting surgeon at the Royal Victoria Hospital—*Science*, May 8, 1936.

THE PRESIDENT OF THE NATIONAL TUBERCULOSIS ASSOCIATION

Dr Esmond R Long, director of the Henry Phipps Institute of the University of Pennsylvania, was elected president of the National Tuberculosis Association at the New Orleans meeting, succeeding Dr James J Waring, of Denver. Dr Hugh S Cumming, Surgeon-General of the United States, retired, was elected an honorary member—*Science*, May 8, 1936.

AN INVITATION TO DR J G FITZGERALD

Dr J G FitzGerald, dean of the Faculty of Medicine and director of the School of Hygiene and of the Connaught Laboratories of the University of Toronto, has been invited by the Rockefeller Foundation to make a study of the methods at present employed in the teaching of preventive medicine to undergraduates in medical schools. It is anticipated that the study will occupy a period of one year from September 15. Dr Charles Edward Smith, of the Stanford University Medical School, San Fran-

cisco, will assist in the undertaking. Uni-
medical schools in the United States and C
the British Isles and in European countries
visited in the course of the survey. Dr Fitz
will resign as dean of the Faculty of Medicine
the University of Toronto on June 30. He
given leave of absence by the governors of the
versity for the necessary period and will, it
pected, return to the university in September
as director of the School of Hygiene and
Connaught Laboratories—*Science*, May 8, 1936.

NEARLY 700,000 BENEFIT FROM SOCIAL SECURITY PUBLIC ASSISTANCE PLANS IN THIRTY-ONE STATES AND THE DISTRICT OF COLUMBIA*

COST WILL BE \$32,033,934 DURING CURRENT YEAR

A total of 690,277 persons are expected to aid during the quarter ending June 30, under public assistance plans so far approved by the Security Board, as was announced May 4. The figure is based on estimates submitted by the States having approved plans, and therefore represents grants in aid from the Social Security Board.

Included in the total number of persons to be aided are 528,694 needy aged, 18,750 needy blind, and 142,878 dependent children.

To date, the Social Security Board has approved public assistance plans in thirty-one States and the District of Columbia. The Board has approved twenty-nine State plans for old age assistance, eighteen State plans for aid to the blind, and thirteen State plans for aid to dependent children. The total monthly expenditure, exclusive of administrative costs, for these three forms of public assistance in all States having approved plans is estimated to be \$10,509,466.05, of which \$8,638,752.42 is for aid to the needy aged, \$478,845.04 is for aid to the blind, and \$1,391,868.59 is for aid to dependent children.

For the three months' period ending June 30, the estimated cost of public assistance in all States having approved plans including payments matched by the Federal Government and cost of administering aid to dependent children totals \$32,033,934.80. This amount includes \$25,926,258.00 for aid to the aged, \$1,413,765.14 for aid to the blind, and \$4,693,911.38 for aid to dependent children.

Based on the States' estimates, the Federal Government's share of the above expenditures for the three months' period will be \$14,536,810 of which \$11,686,100 will go to the States for assistance to their needy aged, \$704,707 for assistance to their needy blind, and \$1,526,384 for assistance to their dependent children.

Under the terms of the Social Security Act, Federal funds are granted to States having approved public assistance plans which conform with the requirements of the Federal act so that the States may provide more adequately for their needy dependent children. The Federal allotments to the States are based on the following basis:

*Report of the Social Security Board, Washington, D. C.

of any amount (not in excess of \$30 a month to an individual) which the State grants to needy persons sixty-five years of age or over and to needy blind, provided these aged or blind persons are not inmates of public institutions. The Federal Government also adds 5 per cent to its half in making its contribution to the States.

Federal grants for aid to dependent children represent one-third of the States administrative expenses and benefit payments under its plan for this form of assistance exclusive of amounts in excess of \$18 per month for the first dependent child in a family and \$12 per month for each additional child.

In addition to State plans already approved the Social Security Board now has under consideration seven State plans for old-age assistance three State plans for aid to the blind and eight State plans for aid to dependent children.

California, Florida, Illinois Montana Colorado New Jersey and Hawaii have submitted plans for old-age assistance Connecticut, Delaware Massachusetts Michigan Minnesota, Rhode Island Colorado, and New Jersey have submitted plans for aid to dependent children and Massachusetts Minnesota, and Colorado have submitted plans for aid to the blind.

To be approved by the Social Security Board a State plan for any of these forms of public assistance must provide for cash payments to needy persons in all parts of the State there must be a single State agency to administer the plan or to supervise the administration if the plan is directly administered by the counties the State agency must have power to hear appeals from any decision denying assistance to an applicant.

Thirty-six States are now sharing in the benefits of those provisions of the Social Security Act which are administered by the Social Security Board and public-assistance plans of four additional States are now being considered for approval by the Board according to an announcement made by Frank Bane Executive Director of the Board.

FEDERAL JUDGES FINE CARELESS CRAB PACKERS

Shipments of germladen crabmeat by three Chesapeake Bay packers brought them into Federal court at Baltimore recently for violating the Food and Drugs Act, the Food and Drug Administration reports.

The actions are the outcome of the campaign begun by federal and state authorities in 1932 to clean up dirty conditions in the crab packing houses in the Chesapeake Bay region so as to guarantee the production of crabmeat free from danger to the consumer. Crabmeat which after cooking is picked from the shells and packed by hand and then refrigerated without sterilization was found to be contaminated with several types of bacteria.—U S Department of Agriculture

CARDIOVASCULAR RENAL DISEASE

Diseases of the heart, arteries and kidneys are of such importance in the national health picture that a special exhibit of charts on cardiovascularrenal diseases was prepared by the Metropolitan Life Insurance Company for exhibition at the Annual Meeting of the American Medical Association in Kansas City Mo., from May 11 to 15.

These diseases present an outstanding problem to the medical profession. The death rate from cardiovascularrenal diseases has not decreased since 1900. During the same period there have been marked declines in mortality from acute diseases of childhood and of early adult life. The cardiovascularrenal diseases stand first in the mortality list today and are responsible for more than a half million deaths annually. After age forty five the death rate from these conditions is four times that from cancer and nearly twenty times that from tuberculosis or diabetes.

Mortality from these diseases is shown in a curve that indicates the age of the victims—slowly rising at first but then more rapidly after age forty five where the progressive degeneration of the heart, kidneys and arteries is reflected in the mortality.

The exhibit stressed the fact that, at the present rate of mortality nearly fifty out of an initial group of 100 children born today in the United States will eventually die from some disease of the heart, kidneys, arteries or cerebral hemorrhage. This is five times the number that will die from cancer and ten times the eventual number of deaths from tuberculosis.

In the agricultural regions of the country relatively low death rates are reported from cardiovascularrenal diseases while the highest mortality is registered among residents on the eastern seaboard.

The exhibit showed that this group of diseases has had an upward trend since 1900 when the crude death rate alone is considered. The aging of the population explains a large part of this apparent increase, as the population over age forty five has increased 100 per cent since the turn of the century while below that age the increase has amounted to only 60 per cent. When death rates for these diseases are standardized they show about the same mortality that prevailed twenty five years ago. In no age period between forty five and seventy five is there evidence of any rise in mortality from these conditions.

At the present time every other death occurring past middle life is from cardiovascularrenal conditions. This compares with one death in three from these causes in 1900 among persons forty five years of age or older.

By 1950 it is expected that 1,200,000 deaths will occur annually from these diseases. This is twice the annual deaths at present from cardiovascularrenal diseases. The rise will attend the increasing proportion of aged persons in the population.

Men are subject to higher mortality from cardiovascularrenal diseases than are women according

to the exhibit This is especially true in the period from fifty to sixty-five years, where the rate for men is 25 to 30 per cent higher than that for women

These diseases take their greatest toll among unskilled workers, with professional men showing high mortality rates Agricultural workers make the best showing, their mortality being only half that of unskilled laborers Among Negroes, between ages forty-five and sixty-five, these death rates are nearly double that for white persons

The exhibit showed that the highest mortality from these diseases occur in the winter months During spring and autumn, the death rates are low, but noticeably higher than the minimum mortality which prevails in summer

CORRESPONDENCE

POOR JOHNNY REB'

May 14, 1936

Editor, *New England Journal of Medicine*,

The following is from "Scraps of Paper" by Marietta Minnigrode Andrews, New York E P Dutton, 1929

"One of my father's stories was that toward the end of the struggle a Confederate soldier, a veritable scare-crow in his rags and tatters, emaciated, unshaven, hungry and foot-sore, and faint from dysentery, accosted a Federal cavalryman, spic and span, as follows

"'Oh my, oh my! You look like you wuz sich a happy man' You got on sich a nice new niform* you got sich nice boots on, you ridin' sich a nice hoss, an' you look like yer bowers wuz so reglar'"

Yours truly,

WM PEARCE COUES, M D

*new niform is correct

RECENT DEATHS

EDWARDS—ARTHUR ROBIN EDWARDS, M D, a retired physician of 416 Marlborough Street, Boston, died May 17, 1936, at his home

Dr Edwards had lived in Boston since 1924 He was a native of Chicago and graduated from Northwestern University in 1888, from the Chicago Medical School in 1891 and was Dean of the Northwestern University Medical School for several years also serving as Professor of the Principles and Practice of Medicine

Dr Edwards was a Fellow of the American Medical Association during his active years, an honorary member of Phi Beta Kappa and a member of the Association of Principles and Practice of Medicine

His widow, Mrs Susannah T (Harrison) Edwards, a son, Arthur Edwards, of Boston, and two sisters, Miss Grace Edwards and Miss Alice Edwards, of La Jolla, California, survive him

SPALDING—HARRY OSGOOD SPALDING, M D, a retired physician of 152 Main Street, Hingham, Massachusetts, died May 10, 1936, following a brief illness

Dr Spalding was born in Hingham, Massachusetts, the son of Dr Henry E Spalding and Mrs Anne O (Frye) Spalding, and after a preliminary education at Phillips Andover Academy and graduation from Williams College in 1894, he entered the Boston University School of Medicine and graduated there from in 1897

Dr Spalding served an internship at the Massachusetts Memorial Hospitals and later was associated with the Norwich Hospital at Norwich, Connecticut, for several years

He subsequently served six years as Superintendent of the Westboro State Hospital and after retiring from this position spent several years as Superintendent of the Wiswall Sanatorium in Wellesley

Dr Spalding was a Fellow of the Massachusetts Medical Society and the American Medical Association, and a member of the American Psychiatric and the New England Psychiatric Societies

Two sisters, Mrs Francis H Lincoln and Mrs Charles E Clapp, both of Hingham, survive him

NOTICE

LAWRENCE CANCER CLINIC

Lawrence, Mass,

May 20, 1936

To the Physicians of the North Half of Essex County

Dear Doctor

The regular Lawrence Cancer Clinic, to be held at Lawrence General Hospital, 1 Garden Street, Lawrence, upon Tuesday, June 2, at 10 00 A.M., will be a Demonstration Clinic, with Channing C Simons, M D, of Boston, Associate in Surgery in the Graduate Courses in Medicine at Harvard University Medical School, Surgeon-in-Chief to Collis P Huntington Memorial Hospital, member of the Cancer Commission of Harvard University, Boston, and Visiting Surgeon to the Massachusetts General Hospital, present as consultant You are invited to accompany any of your patients whom you desire shall have this service, or to send them with a note, and a report will be returned to you The service is gratis Your attendance at the Clinic is always welcome.

This clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society

REPORTS AND NOTICES OF MEETINGS

ESSEX SOUTH DISTRICT MEDICAL SOCIETY

A stated meeting of the Essex South District Medical Society was held April 1, 1936, at the Essex

Sanatorium, Middleton Mass. An interesting and instructive clinic was held by the physicians associated with the institution.

A very significant statement was made and proved that 36 per cent of pulmonary tuberculosis cases will not be diagnosed if examination is limited to the use of the stethoscope without the essential aid of the x-ray film.

Following an excellent dinner the meeting was continued at 7 P.M., in order to listen to the guest speaker Dr. Richard H. Overholt of the Lahey Clinic, Boston.

He presented the subject of "Chest Surgery" in a most interesting and encouraging manner. The temporary forms of lung collapse by means of pneumothorax and phrenic nerve paralysis and the permanent forms by means of thoracoplasty and paraffin pack were carefully explained and illustrated by lantern slides.

The latest developments in the treatment of empyema, emphysema, bronchiectasis and cancer of the lung were instructively presented.

Very remarkable and encouraging were the results shown by the reports of surgical treatment of lung cancer.

NATHANIEL POPE BREXID, M.D., Reporter

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

ANNUAL MEETING

The annual meeting of the Middlesex South District Medical Society was held at the Hotel Continental, Cambridge on Wednesday May 6, 1936. Two hundred and twelve members were present at the meeting and luncheon.

The meeting was called to order and presided over by Dr. Sumner H. Remick.

Dr. Edward Mellins, Treasurer read the following report:

Report of Edward Mellins, Treasurer

In account with

The Middlesex South District Medical Society

April 1935—April 1936

April 15, 1936

We have this day examined the accounts of Edward Mellins, Treasurer of Middlesex South District Medical Society and find them correct.

GEORGE H. HOOPER,
ALVAN C. CUMMINGS,
ARTHUR N. MAKEJEHNIK
Auditing Committee

Dr. Alexander A. Levi, Secretary then read a summary of the meetings held during the past year. In addition, he reported a meeting held by the Councilors of this District at the Middlesex County Sanatorium and expressed the belief that this meeting was the first of its kind ever held in the district. He further reported that the "Hospital Resolutions" which had been adopted by the Society at the October 1934 meeting had been accepted in full by twelve hospitals that the Marlborough Hospital had reported "no action" and that no reply had been received from the Trustees of the Cambridge Hospital. A motion was passed that this matter be returned to the Councilors and officers for further consideration.

Dr. John F. Casey then reported on progress made by the Committee on Immunization. Dr. Enos H. Bigelow made a statement of appreciation of this report and added "The town from which I come has hundreds of children who remain untreated" and hoped that such a splendid group of men will accomplish it.

The names of Fellows who had passed away during the past year were then read by the Secretary. The list is as follows:

Henry S. Rowen, April 29, 1935; Frank L. Newton, May 30, 1935; William D. Swan, June 25, 1935; Arthur H. Ring, June 25, 1935; Frederick E. Withee, June 29, 1935; John J. Murphy, July 8, 1935; Thomas B. McQuaid, September 19, 1935; William H. Clancy, September 21, 1935; Charles S. Cahill, December 10, 1935; Felice Bongiorno, February 20, 1936; Frank E. Bateman, April 5, 1936.

Dr. Sidney C. Dalrymple, the Chairman of the Nominating Committee next presented the nominations for 1936 to the assembly. The ballot was accepted by unanimous vote, the Secretary being instructed to cast one vote to such effect. The list of names of the officers elected (or appointed) for the Society year 1936 is as follows:

President: Sumner H. Remick, Waltham
Vice-President: Fred R. Jovett, Cambridge
Secretary: Alexander A. Levi, Cambridge
Treasurer: Edward Mellins, Newton
Orator: Carl H. Ernlund
Commissioner of Trials: Edward P. Suckney, Arlington

5 Censors: Supervisor 1. Thomas E. Reilly, Marlborough 2. Fritz W. Gay, Malden 3. Michael J. Shannhnessy, Framlingham 4. Charles H. Dalton, Somerville 5. Joseph C. Merriam, Framlingham
Councilors: Charles F. Atwood, Arlington; Elmer

W Barron, Malden, Carl E Barstow, Arlington, Charles F K Bean, West Medford, Enos H Bigelow, Framingham, George F H Bowers, Newton Highlands, Charles O Chase, Watertown, Frank R. Clark, Newtonville, Brainard F Conley, Malden, Alvah C Cummings, Newton, Dana F Cummings, Natick, Hilbert F Day, Cambridge, John E Dodd, Framingham, David C Dow, Cambridge, Augustus W Dudley, Cambridge, H Quimby Gallupe, Newton, Wilfred G Grandison, Charlestown, Fred A Higginbotham, Watertown, Norman M Hunter Hudson, Charles M Hutchinson, Cambridge, Arthur M Jackson, Everett, Alexander A. Levi, Cambridge, Franklin P Lowry, Newton, Frederick L MacDonald, Waltham, Raymond A. McCarthy, Waltham, Lee W McGuire, Malden, John A McLean, West Somerville, Edward Mellus, Newton, Charles E Mongan, Somerville, Frank L Morse, Somerville, John P Nelligan, Cambridge, Edward J O'Brien, Jr, Brighton Dwight O'Hara, Waltham, Charles T Porter, Waltham, William D Reid, Newton, Thomas E Reilly, Marlborough, Sumner H Remick, Waltham, Elliott S A Robinson, Newton, Edward J Sawyer, Newton, Monroe J Schlesinger, Brighton, Edgar F Sewall, Somerville, David W Sherwood, Newtonville, Frederick G Smith, Somerville, Horace P Stevens, Cambridge, Hartley W Thayer, Newtonville, Fresenius Van Nüys, Weston, Ralph H Wells, Lexington, Michael W White, Somerville, Ross K. Whiton, Concord, W Stewart Whittemore, Cambridge, Alfred Worcester, Waltham

Councilor for Nominating Committee Principal, Augustus W Dudley, Cambridge, Alternate, Fresenius Van Nüys, Weston

Signed, ALEXANDER A. LEVI, *Secretary*

Luncheon was then served Following it, the meeting was resumed

Dr Edmund H Stevens was introduced to, and honored by prolonged applause by, the members since this annual meeting was the sixty fifth which he had attended

Dr Charles E Mongan was introduced as the next speaker He said in part that "the first movement to bring about laws effecting the practice of medicine was begun twenty years ago in this District We have succeeded in having a law on the statutes to protect the proper standards of medical practice We found the legislators receptive and willing to listen

"If organized medicine is going to maintain its standards you must take an interest in your legislators You must become politically minded You must have a keen interest in what concerns you most—your Government

"The practical phase is this Five thousand physicians in this State are organized in such a way as never before Your word, your profession must stand for something' I appeal to you—let us maintain what we have gained It behooves us to study these questions

"The Compulsory Health Insurance bill will soon be presented by the authorities in Washington. It

will be a question with you, whether you want it in Massachusetts There is no other state which provides such good care for the sick. One hundred and thirty six million dollars is the capital investment in hospitals in Massachusetts No other state has this In 1933 over 700,000 patients were treated in hospitals of whom 300,000 were treated for nothing Can this capital investment be modified for conformity with compulsory Health Insurance? This is your question. If taxes are too high, philanthropy will decline and many hospitals will be unable to exist. Therefore the change will be greater in Massachusetts than elsewhere To settle this question properly will require work by a large body of intelligent people who will soon be called upon for an answer"

Dr James M Baty, Assistant Professor in the Department of Pediatrics, Tufts College Medical School, delivered the annual oration The title of his paper was "Anemia in Infants and Children" The following is a summary

The average values for the normal blood findings were given, pointing out the wide variations Classification of the causes of anemia in infants and children was presented

An analysis of 1,500 records at the Boston Floating Hospital showed that 514 patients, or 34 per cent, had a definite anemia The incidence of anemia was greater in the infants, the highest incidence being between one and two years of age

The most common causes of anemia in infants and children are infection, dietary deficiency and prematurity In 92 per cent of the above group of 514 anemic patients, the anemia apparently resulted from one or more of these three conditions

The findings and treatment of these conditions were discussed

Summary

1 A careful history, physical examination and examination of the blood are necessary for the accurate diagnosis and adequate treatment of anemia

2 The most important etiological factors in the development of anemia in infants and children are infection, diet and prematurity

3 The treatment of anemia is an important adjunct in the care of the patient, particularly during convalescence from chronic infections The administration of iron usually is sufficient

4 Transfusion is necessary only in rare instances, but at such times is a life-saving procedure

The meeting was adjourned at 1 30 P M

ALEXANDER A. LEVI, M D, *Secretary*

FITCHBURG CANCER CLINIC

The Fitchburg Cancer Clinic Committee held one of its periodic consultation clinics on May 12, 1938 at the Burbank Hospital

Dr Joe V Meigs, Boston, visiting surgeon to the Massachusetts General, Huntington Memorial, and Pondville Hospitals, officiated as consultant.

Approximately 25 doctors attended

The number of patients examined were.....	7
Diagnoses established	
Recurrent cancer of pelvis.....	1
Recurrent cancer of cervix.....	1
Postoperative cancer of cervix no recurrence	1
Possible malignancy of breast.....	1
Postoperative cancer of skin of face no recurrence	1
Defered for dilatation and curettage also amputation of cervix.....	1
Defered for biopsy of growth from neck.....	1
Luncheon was served at the close of the clinic

WOMAN'S AUXILIARY TO THE AMERICAN
MEDICAL ASSOCIATION

The Annual Convention of the Woman's Auxiliary to the American Medical Association was held at Kansas City Missouri May 11-15 1936

PROGRAM

Greetings

Mrs. Herbert L. Mantz, Chairman of Arrangements

Dr. James S. McLester, President, American Medical Association.

Mrs. Walter W. Seymour, Second Vice-President, General Federation of Women's Clubs

From the National Auxiliary Special Articles

Mrs. Rogers N. Herbert, President.

Mrs. Arthur B. McGlothlin, Past President

Mrs. James F. Percy, Past President.

From State Auxiliaries in Western District

News edited by Mrs. James F. Percy

Hypocia in the West, Mrs. Mark Albert Glaser

President Mrs. Rogers N. Herbert, Nashville Tennessee

President Elect Mrs. Robert E. Fitzgerald, Wausau, Wisconsin

Presidents of State Auxiliaries in Western District

Arizona—Mrs. M. O. Comer

California—Mrs. Thomas J. Clark

Colorado—Mrs. C. A. Ringis

Idaho—Mrs. J. H. Crampton

Nebraska—Mrs. R. O. Schofield

New Mexico—Mrs. J. Lopez Garduno

Oregon—Mrs. W. F. Patrick

Utah—Mrs. Leslie J. Paul

Washington—Mrs. J. B. Blair

Wyoming—Mrs. Walter Gray

OFFICERS OF THE AMERICAN SOCIETY
FOR EXPERIMENTAL PATHOLOGY

At the meeting of the American Society for Experimental Pathology held in Washington recently the following officers were elected: President Alphonse R. Dochez, Presbyterian Hospital, New York; Vice-President, C. Phillip Miller, University of Chicago; Secretary Treasurer, Shields Warren, Palmer Memorial Hospital, Boston; Connellors, Morton McCutcheon, University of Pennsylvania Medical School; Ernest W. Goodpasture, Vanderbilt University Medical School. The next meeting of the society will be held at Memphis, Tenn. from April 21 to 24 1937—*Science* May 8 1936

THE FIRST INTERNATIONAL CONFERENCE
ON FEVER THERAPY

The first International Conference on Fever Therapy is to be held at Columbia University, New York City from September 29 to October 3. The subjects to be discussed will include physiologic and pathologic changes as well as the treatment of gonorrhea, gonorrheal and nonspecific arthritis, syphilis, neurologic conditions such as multiple sclerosis, chorea, paresis, tuberculous diseases, etc. The meeting will be held under the chairmanship of Baron Henri de Rothschild of Paris, France—*Science* May 8 1936

AMERICAN ASSOCIATION FOR THE STUDY
OF GOITER

ANNUAL MEETING

The Annual Meeting of the American Association for the Study of Goiter will be held in Chicago Illinois June 8, 9 and 10 1936 at the Drake Hotel. The Scientific Sessions are open to members of the medical profession in good standing. Registration fee \$3.00

CLOVER HILL HOSPITAL

Lawrence, Mass.

The last of the 1936-1937 series of monthly medical lectures at the Clover Hill Hospital will be held in the reception room of the hospital at 161 Berkeley Street, Lawrence, on Thursday evening May 23 1936 at 9 P.M.

Speaker, Albert Warren Stearns, M.D., Dean of Tufts College Medical School, Boston, Mass.

Subject, "Situational Factor in Psychoneurosis."

Following the discussion luncheon will be served. All physicians of Lawrence and vicinity are cordially invited to attend.

N. F. DeCiccarelli, M.D., Chairman

THE MEDICAL LIBRARY ASSOCIATION

The Thirty-Eighth Annual Meeting of the Medical Library Association will be held in St. Paul, Minn. June 22 and 23 1936 and in Rochester, Minn. June 24. Sessions will be held at the Ramsey County Medical Society, New Lowry Medical

Arts Building St Paul and at the Mayo Clinic, Rochester

The program will include addresses, discussions, and demonstrations on library procedure, medical history and literature

Thus Association consists of about 175 of the medical libraries of this country and Canada, together with their librarians and a group of supporting members who are physicians interested in the advancement of medical libraries

The officers of the Association are as follows President Dr W W Francis, Montreal Vice-President Dr A H Sanford, Rochester, Minn, Secretary Miss Janet Doe, New York, Treasurer, Miss Mary Louise Marshall, New Orleans Chairman of Executive Committee Miss Marjorie J Dairach, Detroit

All interested in the development of medical libraries and a wider knowledge of medical literature are invited to attend

BROCKTON MEDICAL SOCIETY

The annual meeting of the Brockton Medical Society will be held on Thursday, May 28 1936 at 7 30 P M, at the Commercial Club, Brockton Massachusetts

PROGRAM

1 Business Meeting

Election of Officers

2 Scientific Program

'The Problems in Medical Economics Today' Morris Fishbein, M D, Chicago, Illinois Editor, Journal of the American Medical Association

3 Buffet Lunch

We are very fortunate in having the opportunity to listen to such an able and well informed authority on what is going on in the world today in matters which are of vital interest to every one of us I hope that every member of the Society will make an effort to be present.

FRED F WEINER, M D., *President*

MILDRED RYAN, M D, *Secretary*,

57 West Elm Street,

Brockton, Massachusetts

THIRD INTERNATIONAL CONGRESS ON MALARIA

The Congress will be held in Madrid from October 12 to 18, 1936 The scientific meetings and the official excursions will take place in the meantime

Various itineraries will be studied in order to allow the Members to visit, during the Congress, the most typical and beautiful towns of Spain, traveling comfortably and at moderate prices

Membership fees—The Members of the Congress will be classified in three categories

1 *Protective Associations*—(Universities, Institutes, Academies, Schools, etc) These Members

shall pay a Membership fee of 250 Ptas (minimum) The Association may appoint three official representatives They will enjoy the same rights as the active Members and receive a copy of every publication of the Congress A fourth copy will be addressed to the Protective Association

2 *Active Members*—As the former members they have the right to vote and send communications to the Congress They may also attend the trips and official receptions They will receive a copy of the publications of the Congress without charge *Membership fee* 50 Ptas (by postal order or check)

3 *Associate Members (Relatives)*—These Members are not allowed either to attend the scientific meetings or to receive the publications of the Congress Notwithstanding, they can attend the entertainments and excursions that will be organized in honor of guests *Membership fee* 25 Ptas (by postal order or check)

Every application must be accompanied by two small photographs for the Member's personal card This card is essential for all matters concerning the Congress as well as for the railway or transport reductions that may be obtained by the Organization

Reports and communications—A duplicate typewritten copy must be sent together with a brief summary for the Press, *no longer than twenty lines* The writers will kindly indicate if films are necessary for the presentation of their work.

Reports must be sent before July 1 Communications will be received until August 15

Subsequently, the Members will receive further information concerning the decisions taken by the Committee

All correspondence shall be addressed to *Dr Manuel G Ferradas, Secretary, Instituto Nacional de Sanidad, Calle de Recoletos, 19, hotel, Madrid (Spain)*

MASSACHUSETTS SOCIETY OF EXAMINING PHYSICIANS

ANNUAL MEETING

Copley Plaza Hotel, Boston, Wednesday, May 27

Dinner at 6 30 P M \$2 50 per Plate

Election of Officers

Papers

1 A Prepayment Plan for Hospitalization Nathaniel W Faxon, M D, Director, Massachusetts General Hospital

Discussion opened by Charles E Mongan, M D, President, Massachusetts Medical Society

2 The Diagnosis and Treatment of Direct Inguinal Hernia in Relation to Industrial Surgery Edward M Hodgkins, M D, Assistant Professor of Surgery, Tufts College Medical School

Discussion opened by William A. Bishop, M.D

- 3 End Results of Epiphyseal Fractures Alex
ander Attkin M.D., Boston City Hospital.
Discussion opened by F J Cotton MD
GEORGE H. R. GOSMAN MD President
WM PEARCE COUES, M.D., Secretary

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at 4 30 P.M., May 25 1936 in the Amphitheatre of the Children's Hospital Boston, Mass. Program 1 An Identical Twin Presenting a Bicuspid Pulmonic Valve. Dr Harry Dietrick. 2 Two Cases of Idiopathic Hypertrophy of the Heart with Recovery Dr Mark I Makler 3 Arachnoidocystitis. Dr Hyman Green. 4 A Case for Diagnosis. Dr Henry F Keever 5 Behavior Difficulties in Children Who Have Attended Heart Clinics. Dr Bronson Crothers 6 Some Cases of Transposition of the Great Vessels Dr Paul W Emerson. 7 A Definite Clinical Syndrome Associated with Enlargement of the Heart in Infants and Young Children. Dr M. A. Kugel (Mt Sinai Hospital, New York)

All members of the New England Heart Association and interested physicians are cordially invited to attend

JAMES M FAULKNER, M.D. Secretary

SOCIETY MEETINGS CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY MAY 25 1936

Monday May 25—

BOOK REVIEWS

Russell A. Hibbs. Pioneer in Orthopedic Surgery 1859-1932. George M Goodwin. 136 pp New York Columbia University Press \$2 00

"Russell A. Hibbs Pioneer in Orthopedic Surgery is a most interesting memorial to a very vivid personality. There were strong farmer ancestors on his father's side who occupied positions of trust in Kentucky communities. On his mother's side there was a touch of medicine for his grand father was both a physician and a bishop in the Methodist Church. Russell Hibbs was the youngest child of ten children and was brought up on a farm

He was graduated from Vanderbilt University in 1888, and received his medical education at the University of Louisville, graduating in 1890 after two terms of six months each. He practiced for a few months in his native town of Birdsville, Kentucky, then settled in Texas for two years, where he was a saddlebag doctor, making his calls on horseback. In 1893 he had saved enough money to make a journey to New York and applied for a position as intern at the Polyclinic Hospital under Dr. John Wyeth. His pay was \$4.00 a week with lodging thrown in. Three dollars a week went for food and one dollar for washing, but he was allowed the privilege of attending without fee postgraduate courses. His interest in orthopedic surgery was excited and the post of superintendent and resident intern at the newly established and struggling New York Orthopaedic Dispensary Hospital becoming vacant, he obtained the position on the approval of the surgeon in chief, Dr. Newton M. Shaffer. This post he filled for four years and then an unfortunate dispute arose with Dr. Shaffer concerning the policy of the dispensary and Hibbs being supported by the trustees, Dr. Shaffer resigned. There followed an appointment as surgeon in chief in December 1900 and within four years of this appointment Hibbs had secured about \$450,000 for the erection and endowment of a country branch of the dispensary at White Plains, for the rising young orthopedic surgeon had become convinced that much of the city dispensary work was futile without a convalescent home outside the city where these long chronic cases could be properly cared for. By 1924 the bed capacity had grown from fifty to one hundred and sixty-five beds and the endowment to a million and a half dollars.

Hibbs was largely instrumental in the establishment of the New Jersey Orthopedic Dispensary and Hospital at Orange.

In 1916, after ceaseless efforts of persuasion, the trustees of the New York Orthopaedic Dispensary and Hospital recognized the need of a more adequate building. The present building on East 59th Street was erected, and after a struggle a sufficient endowment for this hospital was secured and in 1925 a clinic for private patients was opened.

These more or less administrative accomplishments did not prevent Hibbs from doing important original research and the book states fully his various important contributions to the surgery of bone and joint diseases outlined in such a way that the lay reader may understand their significance.

Hibbs will be remembered as the great advocate of what he termed "fusion operations" designed to provide complete immobilization of tuberculous joints without the use of external apparatus. He reached the conclusion that this was the treatment par excellence whenever the patient's condition warranted it as a means of preventing its spread to other regions, affording the most permanent form of cure and the saving of great social and economic wastage which the standard methods then in vogue

entailed because of the length of time required to bring about even partially successful relief.

Hibbs was appointed professor of orthopaedic surgery in Columbia University in 1919 and he was elected a member of the American Orthopaedic Association in 1921. He fought for the principle of salaries for the hospital staff and won, so that the New York Dispensary and Hospital was almost unique in this respect at the time the change in policy was made. In 1929, by the will of Mrs. John I. Kane, a million dollars was left to the hospital for scholarships for continuing training and research, which scholarships are awarded to promising young surgeons. Dr. Hibbs was almost entirely responsible for this bequest and this was his last contribution to orthopedic surgery. He died in 1932 from the results of a coronary occlusion.

There is an interesting short description of Hibbs as a sportsman by Dr. Samuel W. Lambert and a feeling tribute by Dr. Karl Vogel. The book also contains appendices or original papers: (1) The Lengthening of the Tendo Achilles (illustrated), (2) An Operation for Stiffening the Knee Joint (illustrated), (3) An Operation for Progressive Spinal Deformities (illustrated) and (4) A Preliminary Report of Twenty Cases of Hip Joint Tuberculosis Treated by an Operation Devised to Eliminate Motion by Fusing the Joints (illustrated) and a chronological bibliography from 1923 to 1931.

This modest volume of some 130 pages will interest a wider audience than orthopedic surgeons. We hope that laymen and women as well as the medical profession will make up this audience, for a well told story of early struggle and eventual success (when success is deserved) is always worth reading.

The Kidney in Health and Disease Edited by Hilding Berglund, Grace Medes and others. 754 pp. Philadelphia: Lea & Febiger. \$10.00.

This is a large volume of nearly eight hundred pages, comprising the work of forty-one contributors. The work is really the outgrowth of the symposium on the structure and function of the kidney in health and disease which took place in Minneapolis in 1930. The book is divided into six sections beginning with the "Anatomy and Physiology of the Kidney" and ending with the "Clinical Aspects of Bright's Disease." Each chapter in the book is carefully and thoroughly outlined and is followed by a complete bibliography.

The book is hardly intended for the general practitioner. Its greatest usefulness will be as a reference work for students and physicians who are especially interested in nephritis and allied problems. In this respect the convenient arrangement of chapters and the obvious effort of each contributor to state clearly the general principles involved, adds greatly to the practical value of the work. The book is really a comprehensive and authoritative exposition of present knowledge in a single field of medical science and for this reason alone, is decidedly worth while.

The New England Journal of Medicine

NUMBER 22

PROTAMINE INSULIN

BY ELLIOTT I. JOSLIN, M.D.† HOWARD F. ROOT, M.D.† ALEXANDER MARBLE, M.D.†
PRISCILLA WHITE, M.D.† ALLEN P. JOSLIN, M.D.† AND
GEORGE W. LANCY, M.D.†

INTRODUCTION Eleven year old B. W. showed 10 per cent of urinary sugar upon the morning follow up the discovery of his diabetes and began the use of protamine insulin forthwith (Figure 1). Thirty units were given before breakfast on the first day 50 units on the second, third and fourth and upon the fifth day the urine was sugar free although the patient had received in the previous twenty four hours 210 grams of carbohydrate and 1000 calories. He had no reactions and eleven days later while at home was sugar free with a normal blood sugar. By that time his insulin had been reduced to 24 units before breakfast. It is true he was a fresh case and a child but contrast this experience with the inauguration of treatment with former methods.

Mrs. S., a nurse thirty-six years old so crippled with rheumatoid arthritis that exercise was impossible in the treatment of her diabetes of one year's duration weighed eighty four pounds in July 1935. To control her diabetes she required insulin in enormous amounts given in four to six doses daily for six months. At one time she took as high as 530 units a day. Since January she has shown improvement, her weight has risen to 117½ pounds and the insulin was decreased to 240 units administered before meals and on retiring. Upon January 23 she began protamine insulin and now in April her diabetes is equally well controlled with insulin once daily 120 units of the old and 120 units of the new (Figure 2).

Her parents told me (E. P. J.) that since her severe reaction ten years ago they had not dared to let her sleep alone. This last autumn the week after entrance to a college in Boston while at lunch with her mother at a restaurant she had a reaction so violent that it was necessary to call an ambulance and remove her to a hospital. Immediately she began protamine insulin and is now taking 40-60 units.* Her mother says: "Since R. commenced protamine insulin she has had no reactions. She sleeps alone. You cannot tell Dr. Joslin what protamine insulin means to her father and me."

DESCRIPTION OF PATIENTS. All told, we have given protamine insulin since last August to more than 100 diabetics but only the cases studied before April 1 are summarized in this report. Of these ninety one patients, forty six were males. All began it in the hospital. Their ages ranged between four and seventy

six years thirteen being children fifteen years old or less, and the duration of the diabetes a few days to twenty-eight years. Sixty six patients continue to take it, and the great majority of these are using it in their homes. No patient who began it has died developed diabetic coma or acidosis, or, as a matter of fact, *de novo* any complication common to diabetes such as lesions of the legs or carbuncles. This is not particularly strange, because the patients were selected for intelligence and reliability. One patient of eight years' duration with reactions of considerable intensity in the past has developed what at first we thought was neuritis but probably is proving to be multiple sclerosis. However it is our impression that the sixty-six patients now taking protamine insulin alone or in conjunction with old insulin live far more comfortably more safely than before and with less inconvenience to themselves or their families and that they can take a somewhat wider range of carbohydrate in the diet without showing an increase in glycosuria. We are convinced as previously reported^{1,2} that protamine insulin represents a great advance in diabetic therapy.

TABLE 1
NINETY-ONE DIABETICS TREATED WITH PROTAMINE INSULIN

Age by Decades	Number of Cases	Average Duration of Diabetes Yrs.
0-9	6	2.9
10-19	40	6.7
20-29	7	11.3
30-39	8	8.6
40-49	13	10.0
50-59	8	6.2
60-69	6	12.5
70-79	3	14.0

In an estimation of the value of protamine insulin one is forced at the moment to depend upon immediate results such as prolongation of the action of insulin and freedom from reactions, but beneficial as these are we consider them to be insignificant in comparison with the better control of the diabetes which it makes practical. Formerly a diabetic could maintain a reasonably normal blood sugar for one half

Joslin, Elliott I. — Medical Director George F. Baker (Cline New England Deaconess Hospital, Root, Howard F. Marble, Alexander and White, Priscilla — Physician to the New England Deaconess Hospital, Joslin, Allen P., and Lancy George W. also see these for records and addresses of a short note "This Week Issue" page 1187

two-thirds or three-quarters of the twenty-four hours, but consider what this signified if applied to the course of his diabetes throughout twenty years—the average duration of diabetes with onset in 1936. It would mean that for one-half to one-quarter of this period, namely ten to five years he would be living with an abnormal blood sugar with all its implications. And it is this long range view of the diabetic problem which is ultimately the more important.

THE HAGEDORN ERA Whereas the Banting Era made possible the conquest of coma, the Hagedorn Era makes possible the approximation of the physiological processes of the diabetic so nearly to normal that arteriosclerosis should cease to be his distinctive enemy. Protamine insulin has broken the spell of content which the original insulin induced. Now we know improvement in insulin is possible. These are the chief reasons that for ourselves we think it only fair and a just due to the Copenhagen investigator to name this present era the Hagedorn Era.¹

We will next present the technique we have employed in the administration of protamine insulin: the dosage, the diets, the untoward effects such as reactions, hypoglycemic or allergic, the apparent lack of control of the disease in the inauguration of treatment and the reasons why having begun protamine insulin certain patients omitted it. Finally, we will state as best we can the indications for its use and the suggestions we have for its employment with new diabetics and for the transfer to new insulin of diabetics already under treatment with old insulin.

GENERAL TECHNIQUE The diabetic patient can be treated entirely with protamine insulin or with combinations of old and protamine insulin. With fresh cases of diabetes we have been greatly impressed with the effectiveness of the use of protamine insulin exclusively and believe that it is desirable to follow this up intensively. When both old and protamine insulin are employed our most consistent results have been secured by following the original suggestion of Hagedorn² of giving old insulin in the morning and protamine insulin before the evening meal. The cases we started upon this plan nine months ago have done remarkably well and so well that they furnish a standard for comparison with other methods.

A small number of patients have been given both old and new insulin before breakfast and old and new insulin before the evening meal and a group of these have found this method so satisfactory that we hesitate to change them to other types of treatment. Knowing in advance the results obtained by Campbell, Best and Wilder^{4, 5} with simple doses of old and protamine insulin given separately before breakfast, we

have tested this method more especially in the last few weeks and it has worked well.

DETAILS OF ADMINISTRATION The present protamine insulin compound in use in this country is obtained, as in Copenhagen, by mixing two solutions which come in separate bottles. In the first is a solution containing standard insulin of U-50 strength. In the smaller bottle accompanying the larger one in the same package is a solution containing protamine derived from fish sperm. When 1 cc. of the protamine solution is injected into the bottle containing the U-50 insulin, a cloudy, milky mixture is formed which is really a suspension of the finely divided and almost insoluble protamine insulin compound. This compound has its point of minimum solubility at pH 7.3, or at about the reaction of blood serum. This cloudy suspension is injected.

The effectiveness of the new protamine insulin depends upon the fact that the compound at the reaction of body tissue is very slowly assimilated. Therefore, when it is injected into human tissue, there is formed a depot which is slowly and gradually drawn upon by the body during the ensuing ten to twenty-four hours. The duration of the action apparently varies. In one normal nurse we found that the blood sugar was still falling at the end of ten hours after the injection. Other observations show that if a rather large amount is deposited that the blood sugar lowering action is still demonstrable for a full twenty-four hours or longer after the injection.

EFFECTS UPON THE BLOOD, URINE AND TISSUES Local tissue changes, due to allergy, have not been observed at the Deaconess Hospital although one such case has been reported elsewhere and another in one of our discharged cases. No abscesses followed its use, and so far as we know no new areas of fatty atrophy have occurred. It has been stated that when this substance is injected into animals and the tissues are subjected to pathologic study, there is no evidence of the substance acting as a foreign body and attracting to it collections of leukocytes. There is no positive chemotaxis. The typical effects are shown in figures 1 and 3. In figure 1 on the second day of treatment, the blood sugar fell so much during the night that a normal level was reached twenty-four hours after the dose of 50 units. On the fifth day of treatment, the morning rise in the blood sugar came under control. In figure 3 another boy's record shows control of former wide oscillations in blood sugar within a narrow range. In such severe juvenile cases there is apt to be an elevation of blood sugar during the night which sometimes develops into mild acidosis. This is prevented by this treatment.

The administration of protamine insulin is

cause the dose may have been increased so markedly as a result of heavy glycosuria that at the end of that period unnecessarily large amounts are being employed. Especially is one apt to obtain reactions at this time if old insulin and protamine insulin are combined before breakfast. It is so unusual for us doctors to expect our patients to have normal blood sugars early in the morning that a reaction may be precipitated if the patient receives quick-acting old insulin a half hour or more before his morning meal. Therefore, we have recently made it a rule that no patient taking old and new insulin should have it injected more than thirty minutes before taking food. It is because of

figure 2. The smallest dose was 5 units in a three year old girl with incipient diabetes of recent onset.

DIETS Protamine insulin works successfully even if the carbohydrate in the diet varies from 100 to 275 grams. The ideal carbohydrate would be such a value that would allow the patient to learn it readily and easily, adhere to it, and then take a quantity of protein normal for his age and size, and fat sufficient to maintain a proper weight. Undoubtedly, the individual patient can adjust the distribution of carbohydrate advantageously in various ways according to his method of living. It is our

FIG. 3—Case 11906. A aged eleven was uncontrolled with 57 units of ordinary insulin in three doses in December 1935. The above chart shows improved control of the blood sugar with ordinary insulin 22 units and protamine insulin 62 units taken simultaneously.

the days required to adjust the diabetic to the new insulin and the possibility of reactions at the end of a few days, that we believe the general distribution of the protamine insulin should proceed slowly. However, the general control of the diabetes which it allows may counterbalance this temporary danger if doctors and patients can be taught to wait five days more or less for it to exert its complete effect.

In changing from old to new insulin it is probable that in the controlled case approximately the same number of units will be employed. For the first few days following the shift the glycosuria will increase, but eventually it will disappear and in a considerable number of patients the reports have come back that the patient needs less rather than more total units than before the protamine insulin was started. By no means can this statement be made unequivocally.

The largest single dose has been 120 units, given in the fasting state simultaneously with 120 units of the ordinary insulin as shown in

impression that an increase of 20 grams from the patient's customary amount for a single day produces fewer alterations in glycosuria than would take place when under treatment with old insulin. The diets used in eighty-eight cases included carbohydrate less than 150 grams in twenty-three cases, between 150 and 200 grams in forty-one cases, 200 to 250 grams in twenty-two cases and above 250 grams in only two cases.

PROTAMINE INSULIN THERAPY Until within a week we have believed it to be unwise to begin the use of protamine insulin on patients outside the hospital. The average period of hospital stay has been fourteen days for eighty-eight cases treated at the George F. Baker Clinic, excluding three cases with exceptionally long stays in the hospital because of complications and a group of children living in the Prendergast Preventorium. Perhaps the chief reason for insisting upon hospital observation was our desire to study effects of treatment by means of frequent blood sugar determinations and the

fact that in many patients there is a latent period of from two to five or six days during which time there is apparently little effect from the protamine insulin. During this time, one is tempted to increase the dose to a dangerously high point, as already mentioned. If this is done then there is a sudden change on the fourth or fifth day after the beginning of treatment and a fall of blood sugar which is so rapid and may be so great that serious and persistent hypoglycemia may result. The frequency of hypoglycemia during this period of adjustment may be seen from the fact that there were 149 blood sugar determinations among a total of 1772 of 0.05 (50 milligrams) per cent or lower four of which were 0.02 (20 milligrams) per cent. The change in character of treatment brought about by protamine insulin is well shown because the total number of insulin injections in this group of patients was reduced from 274 to 189, or 25 per cent. This reduction does not appear so large as one might expect because it contains a good many of the early cases in whom the reduction in number of doses was often only from four to three and also cases in whom the number of injections was not reduced at all, the end sought being the better control of the diabetes. In our more recent cases, however, a reduction of four injections a day to two injections given at the same time before breakfast has become almost the rule and therefore a much greater change in the character of treatment is wrought. In eleven patients the number of injections was reduced from four to three, in fifteen cases from four to two, and in one case from four to one. An increased number of injections was necessary in thirteen cases entering the hospital with uncontrolled diabetes. Since April 1 the reduction in number of injections has reached a much greater per cent.

DURATION OF TREATMENT Up to April 1 1936 the use of protamine insulin had been discontinued in twenty five cases leaving sixty six patients who had used it continuously for periods shown in table 2.

TABLE 2
DURATION OF TREATMENT WITH PROTAMINE INSULIN

Protamine insulin may be and has been omitted with safety and regular insulin substituted

far it. This has taken place especially under conditions such as resulted from the floods in New England which prevented shipments. Usually a reduction in the number of units by approximately a fourth suffices to avoid the possibility of reactions. Certain patients were able to give up all insulin because of such improvement that their urine was sugar free without insulin. Others who began protamine insulin in September and October, 1935 were discontinued because of a deliberate intention to restrict its use to hospital patients at first. A small number of patients preferred to return to their customary doses of old insulin believing that to be equally effective in their own case.

HYPOLYCEMIC ATTACKS Attacks of hypoglycemia are by no means impossible when the patient is taking protamine insulin. With administration in excessive dosage a low blood sugar level can be produced just as with regular insulin. However, the action of the new preparation is so gradual that with proper care the danger of insulin reactions is largely avoided. This has been the greatest immediate benefit that the use of protamine insulin has conferred.

When hypoglycemia arises from a single excessive dose, the effect is seen naturally eight to twenty four hours from the time of injection. Thus a patient who is given an excessive dose in the evening before supper may wake up the next morning with a reaction. This is more apt to occur if the protamine insulin is given twice daily, as for example in the morning before breakfast and in the evening before supper. Then a 'pyramid' effect may be seen if the doses have been too large. Early in our experience with the new insulin this occurred with one small boy, aged four and a half years, in whom we were attempting to control glycosuria solely by the use of protamine insulin in a morning and an evening dose. In an effort to control hyperglycemia in the late forenoon, the before breakfast dose of protamine insulin was made unwisely large. Then another dose of protamine insulin was given before supper. The result was a series of hypoglycemic attacks in the early morning hours.

A word of caution should be spoken to those who adapt the system of giving regular insulin before breakfast and protamine insulin before supper. Because of the prolonged effect of the latter the patient will awaken in the morning with a lower blood sugar level than under the old régime. Hence the action of the dose of regular insulin taken before breakfast will be more effective and unless this fact is recognized and the dosage reduced a reaction in the late forenoon may result. Furthermore the older insulin should be given within thirty to fifteen

minutes before breakfast to aid in the prevention of a reaction although it must be said that even if given immediately before or after breakfast a reaction may not be averted or even ended if already begun.

With most patients hypoglycemic attacks due to protamine insulin are apt to come on more slowly thereby giving more time for intervention before marked symptoms arise. It has been supposed that patients when using the protamine insulin seem to tolerate lower levels of blood sugar for longer periods without the usual symptoms of hypoglycemia. Our own experience does not bear out this impression. Best⁶ has shown that in dogs receiving protamine insulin such asymptomatic hypoglycemia may exist for eighteen to thirty hours without apparent damage to the animal and has assumed that this was so, because the tendency to lower blood sugar levels was exerted so mildly and so gradually that the bodily secretion of epinephrine was able to exert the proper counter-effect.

It is characteristic of marked hypoglycemia (in patients) due to protamine insulin that a series of reactions is apt to occur. For example, relief may be secured following the administration of carbohydrate in small amounts but some minutes later the hypoglycemic symptoms may reappear and so on. This type of action is to be expected when the blood-sugar-lowering effect is due to the gradual and continued release of insulin from a bodily depot.

Mention has been made (Editorial, *Annals of Internal Medicine*⁶) of the greater frequency of rather severe headache during hypoglycemia with the new insulin than with the old. We have not noticed any marked difference with our series of cases between old and new insulin. In fact, Mrs. St. C. experienced very severe headaches lasting even for three days when she had a reaction resulting from the old insulin.

DURATION OF EFFECT OF PROTAMINE INSULIN

In Hagedorn's original paper and in Klarup's monograph from his clinic, it is stated that the effect of the slowly-acting insulin could be demonstrated at least twelve to fourteen hours after the injection. Subsequent experience has shown that this is a very conservative estimate. With the preparations in use at the present time an effect at least twenty-four hours distant from the time of administration is demonstrable. This is borne out by our daily experience in those patients to whom we are now giving insulin at only one time of day, viz., a dose of the regular and a dose of the protamine insulin (in different areas) before breakfast. With Wilder's case at the Mayo Clinic this prolonged action was forcefully illustrated. On the first test day the patient was given 35 units of regular insulin and her breakfast. No more insulin or food was allowed during the next twenty-four

hours. On the following morning the patient was in definite acidosis, was vomiting and had a blood sugar of 425 milligrams per cent and a plasma CO₂ combining power of 28 volumes per cent. Repeated doses of regular insulin were required to bring the patient out of acidosis. Three days later the test was repeated except that an equivalent dose of protamine insulin was given before breakfast in place of regular insulin. Although the patient exhibited much glycosuria during the day, this cleared up during the night and on the following morning a single specimen of urine contained only a trace of sugar and the blood sugar was 270 milligrams per cent. The patient was clinically in good condition.

Scott and Fisher⁷ have found that in animals the addition of a zinc salt to preparations of insulin further prolongs and makes more gradual the blood-sugar-lowering effect. These investigators suggest that zinc or other metals may play a part in the union between insulin and protamine, but very likely its effect may be simply to stabilize the product and make the precipitate less likely to adhere to the wall of the vial.

Beecher and Kiogh⁸ have made microscopic observations upon the absorption of insulin and protamine insulin.

DOES PROTAMINE INSULIN DETERIORATE AFTER FOUR OR FIVE DAYS? It is difficult to get clear-cut proof of the durability of protamine insulin solution or, on the contrary, of its deterioration because patients who come into the hospital are under active treatment, and both the diet and insulin dose are apt to be changed. In order to test this point, the protamine insulin was mixed, and a single bottle was used daily for the same patient for periods from three to ten days in length. In two cases on the fourth and fifth days there occurred a marked increase in sugar in the urine and a rise in the blood sugar curve. However, both were new cases so far as use of protamine insulin was concerned and might have reacted differently if the test had been carried out after a period of previous treatment with protamine insulin. The daily records of another case sometimes clearly indicated that the insulin deteriorated at the end of three, four, or five days. On the other hand, at other periods, no such evidence of deterioration appeared in his tests.

In a considerable group of patients outside the hospital who sent in daily charts no constant change in their urine tests occurred at the end of four or five days. Therefore we do not feel certain that loss of potency actually took place. We understand that stabilizing substances are now being tried and a future gain in stability of the protamine insulin mixture is probable.

THE INDICATIONS FOR USE OF PROTAMINE INSULIN 1 A trial should be made with diabetes of recent onset because it is probable that such patients can be controlled with a single daily dose of protamine insulin from the beginning of treatment. Indeed it is our impression that we will never learn what protamine insulin can do until we use it as a remedy *en generis* and observe patients treated with it exclusively over a period of years.

2 High fasting blood sugar values are a definite indication because of the great advantage to a diabetic in beginning his day with the nearly normal metabolism indicated by a normal blood sugar.

3 Multiplicity of dosage can be avoided by the use of protamine insulin and the consequent gain in simplicity and convenience of treatment improves the end result.

4 Sensitivity to insulin as indicated by frequency of reactions constitutes the fourth major indication.

5 Hepatomegaly is an indication because of the efficacy of protamine insulin in reducing the size of the liver reported by Hansen.

6 Lipodystrophy may be favorably affected by the reduced number of injections and lessened acidity of the preparation.

7 Finally it may prove to be of especial value in mild diabetes in patients with hyperlipemia, cardiac cases in whom hypoglycemia should be avoided and for the same reason where there are occupational hazards.

CONCLUSION With protamine insulin the fundamentals of treatment of diabetes are not changed but the ideals of treatment are more nearly achieved. Diabetes today is a disease to be respected and neglect to do so spells disaster. Diet and exercise are as essential as ever. The patient must not overeat but it seems likely that having determined the insulin dosage for a given quantity of carbohydrate, the protein can be determined by adjustment to the age and size of the patient, the fat regulated by body weight and even the carbohydrate can vary ten to twenty per cent up or down with comparative impunity.

The simplicity of administration of insulin in one or two doses instead of two three, or four doses will appeal so generally to patients that the probability is strong that the number of diabetics taking insulin will increase. As a result the percentage of deaths from coma should fall at an accelerated pace.

The original hope that protamine insulin would be safer, because of the lessened number and severity of insulin reactions which it engenders has been confirmed.

Thus for those diabetics characterized by high fasting blood sugar values by the need of three or four doses of insulin or by sudden and serious insulin reactions have been those selected for trial with protamine insulin and recently we have begun to employ it with fresh cases. Knowing that it helps severe diabetes there is no doubt that it will help the milder cases and we are confident that soon the great majority of patients will adopt it.

Best of all is the hint that the more complete control of the disease which the new insulin makes possible may so raise the standard of bodily health that the diabetic will be less subject to and will resist more successfully the various so-called diabetic complications infections, vascular degeneration and abnormal neurologic and ophthalmologic manifestations.

HYPOPHYSIS AND BLOOD PRESSURE

BY BERNARDO A HOUSSAY, M D †

IN 1894 Oliver and Schafer¹¹³ discovered that pituitary extracts raised the blood pressure, Howell⁷⁸ showed that this action was due to the posterior lobe, and in 1928 Kamm⁸⁵ and his collaborators separated the vasopressor and the oxytocic principles*. It came to be believed early that the pituitary played an important part in the regulation of the arterial pressure¹⁰⁶ Azam¹⁰ and Dehille,⁴⁴ a pupil of Renon, attributed the lowered blood pressure, accelerated pulse, etc., of acute infections to an insufficiency of the pituitary, since treatment with the extract corrected these symptoms, Renon even postulated a syndrome of hyperpituitarism with hypertension and bradycardia. But in spite of many theories there were few facts to support them, and in 1932 Dale⁴¹ concluded that it was not possible to say what part the vasopressor principle in the posterior lobe played in the maintenance of normal blood pressure. Nevertheless numerous experimental and clinical observations indicate that there may be a relation between the pituitary and the blood pressure level. We will describe and discuss these observations in this paper.

ARTERIAL BLOOD PRESSURE IN EXPERIMENTAL
PITUITARY INSUFFICIENCY

Amphibians—The toad's pituitary contains substances which raise the blood pressure of the dog,⁷² the cat⁶⁴ and the toad¹¹⁴. The neuro-intermediate lobe is more active than the principal lobe in this respect¹¹⁴. The vascular system of the batrachians is sensitive to the vasopressor substance in the mammalian pituitary,^{1 14 55 74 93 113 114 118} etc. but Hogben and Schlapp⁶⁹ had to use such large quantities to produce effects, that it was not possible to consider them physiological.

A few hours after complete extirpation of the pituitary in the toad the capillaries and arterioles of the skin become dilated^{9 94}. Injection or perfusion of pituitrin, even in doses of 1 1,000,000 re-establishes the capillary tone and larger doses produce a contraction of the arterioles as well. From these facts Krogh⁹³ deduced that the pituitary, by means of a hormone, had a continuous action on the tone of the capillaries ‡.

*Extensive bibliographies on the vasopressor activity of pituitary extracts will be found in Houssay⁷⁴ Gelling⁸⁷ Trendelenburg¹⁴⁶. My own work on the subject will be found in my book⁷⁴.

†Houssay Bernardo A—Professor of Physiology Faculty of Medical Sciences University of Buenos Aires 1919—For record and address of author see This Week's Issue page 946 issue of May 7.

‡Krogh also brings evidence for the presence of the hormone in the blood of mammals. Thus in ox serum there is a substance which constricts the capillaries. It is dialyzable insoluble in alcohol and ether soluble in methyl alcohol and thermostable.

The removal of the principal lobe produces a similar but transitory alteration,^{9 94} since the normal tone is soon recovered,⁹⁴ though in some cases the recuperation may not be complete.⁹ In the toad when the nutritional disturbances and asthenia are marked, usually about one month after the lobectomy, the vasodilatation again becomes pronounced. Infundibulotuberal lesions produce only a moderate and passing dilatation.⁹ The dilated capillaries are unstable,⁹⁴ but react well to thermal stimuli.⁹ According to Nogaki,¹¹¹ however, the contractile capacity of the vascular system is reduced in the hypophysectomized frog.

Blount²⁸ produced a state of hyperpituitarism in the larvae of *Amblystoma*, by grafting two extrahypophyseal anlagen. In these animals he observed vasoconstriction, bradycardia, hypertrophy of the ventricle, and sometimes edema. The basal membrane of the glomeruli of the kidney was thickened, the glomeruli were diminished in size and in some the capillaries became obstructed, these lesions are similar to those seen in human hypertension.²³

Orias has done important work in our Institute, showing that the intermedio-neural lobe plays a considerable rôle in the maintenance of normal blood pressure in the toad *Bufo arenarum* (Hensell). Removal of the principal lobe alone did not alter the blood pressure until the nutritional disturbances and neuromuscular asthenia appeared, when it was found somewhat lower (30 mm Hg) than in the controls which had only been craniotomized (39 mm Hg) (Fig 1). When the whole pituitary was removed, i.e., the neuro-intermediate together with the principal lobe, the blood pressure began to fall within a few hours after the operation. At times there was a transitory reaction in about twenty-four hours, but afterwards the decrease continued and an average blood pressure of 24 mm Hg was found one week after operation and of 17 mm one month later. The injection of extracts of either lobe raised the blood pressure but the neuro-intermediate was the more active. The fall in blood pressure could be prevented by daily implantation of one lobe, either glandular or neuro-intermediate. Neubach (unpublished data) showed that intravenous injection of 3 cc arterial blood from a normal toad produced a significantly greater increase in the blood pressure of hypophysectomized toads than did the same quantity of blood from hypophysectomized toads.

Several facts indicate that the vasopressor and melanophore dilating activities are due to different substances. The following evidence

may be so interpreted namely that after removal of the pituitary the skin blanches before the blood pressure drops that there are certain differences in the pharmacological and chemical characteristics of the two hormones^{4 46 47 54 56} etc. and, of even more significance that Dietel^{48 49} has isolated a melanophore dilating substance which, far from having a pressor effect dilates

the capillaries and decreases the blood pressure. He believes it may also have a part in regulating the blood pressure

Animals—Braun Menendez^{4 22 4} measured the blood pressure in twenty-five hypophysectomized dogs in our Institute. Only three of the operated animals had a normal blood pressure and the average value (108 mm Hg), was lower than that found in twenty-one normal controls (127 mm Hg). Lesions of the tuber did not modify the blood pressure, the average

FIG. 2

tomized dogs in our Institute. Only three of the operated animals had a normal blood pressure and the average value (108 mm Hg), was lower than that found in twenty-one normal controls (127 mm Hg). Lesions of the tuber did not modify the blood pressure, the average

being 124 mm Hg in thirteen experiments nor did the removal of the posterior lobe produce a significant decrease, the average being 120 mm Hg in four dogs (Fig. 2). It must be noted that in these experiments the extirpations were not complete, since the *pars tuberalis* remained in the hypophysectomized animals, and in those whose posterior lobe alone was removed, fragments of the *pars intermedia* were left behind.⁴

Braun Menendez^{22 20} was able to demonstrate that the vasomotor reactions were less adequate in the hypophysectomized than in normal dogs. When dogs were bled from the carotid to the extent of 15 per cent of the body weight the blood pressure fell 30 to 40 mm Hg. In six experiments on normal animals the pressure returned to its initial level in 25 to 75 (average 45) minutes, whereas in nine experiments on hypophysectomized animals the initial pressure was not re-established until 75 to 130 (average 95) minutes following bleeding (Fig. 3)

FIG. 3

Dotted line—average of nine hypophysectomized dogs
At arrow the animal were bled from the carotid artery to the extent of 15 per cent of the body weight.
Abcissae—Time in minutes
Ordinates—cm Hg.

In the rat, removal of the posterior lobe does not alter the blood pressure significantly, the observed pressures being within the normal range, though somewhat low. Their sensitivity to histamine also is not increased. On the other hand complete hypophysectomy is followed by a decrease in blood pressure and there may be a lowered resistance to histamine.⁵⁵ Yamashita⁵⁴ also found a lowered blood pressure in the rabbit after partial hypophysectomy.

BLOOD PRESSURE IN HUMAN PITUITARY INSUFFICIENCY

In patients with chromophobe adenomas of the pituitary the systolic pressure is usually low.^{13 20 21 26} Cushing²⁶ found it to be below

Dr. Braun Menendez did his work. I had measured the blood pressure in a hypophysectomized dog in 1911 and Foster and Green⁴⁸ did the same in two dogs. Braun Menendez and I also found a lowered blood pressure in the rat.

100 mm Hg in 11 per cent and below 110 in 46 per cent of his 200 cases, while only two had an abnormally high blood pressure. In craniopharyngiomas it is lower still. Peiémy¹⁻⁰ found the blood pressure to be between 78 and 110 mm Hg in 20 out of 45 cases of hypophyseal tumor.

In many cases of pituitary cachexia there is a low blood pressure, as noted in the papers by Graubner,⁵⁹ Calder³⁰ and others more recently. The vasomotor reactions are also disturbed.¹³² After muscular exercise both the systolic and diastolic pressures fall markedly, and the same may happen when the patients resume the erect posture after a period of reclining. This circulatory collapse frequently occurs in such patients and may be corrected by treatment with anterior lobe extract. Nevertheless it cannot be attributed specifically and primarily to the hypophysis, since it is a common occurrence in other types of cases which have a low blood pressure and marked loss of weight. Thus, it has been seen in hypothyroidism and in cases of tabes dorsalis. In spite of this, Schelling believes that the pituitary anterior lobe is of importance in the regulation of blood pressure. Ratner¹²⁰ found these circulatory disturbances in ten cases, and attributes them to adrenal insufficiency due to a deficient secretion of the pituitary adenotropic hormone.

BLOOD PRESSURE IN ACROMEGALY

The postmortem examination of acromegals often reveals arteriosclerosis and enlargement of the heart. Numerous instances of increased blood pressure have been reported in these patients.^{2, 8, 31, 32, 40, 63, 80, 108, 116, 117, 119, 121, 122, 155} and death is frequently due to cardiac insufficiency. Nevertheless the pressure was low (below 120 mm Hg) in 30 out of 100 cases of acromegaly studied by Davidoff⁴³ and in 28 per cent of those seen by Rowe and Lawrence.¹²⁰ According to Kyhn,⁹ in cases of acromegaly occurring in Sweden and collected by Biennig, the blood pressure was normal in young subjects, in only two was it above 140 mm Hg, but in the patients forty or more years old 11 per cent of the men and 60 per cent of the women had a high blood pressure. Henstell⁹¹ says that paroxysmal hypertension may occur in acromegals.

PITUITARY BASOPHILISM AND THE BLOOD PRESSURE

We owe to Cushing the recognition of a clinical syndrome characterized by adiposity, dorso-cervical kyphosis, amenorrhea or impotence, hypertrichosis, plethoric skin with atrophic striae, high blood pressure, glycosuria, osteoporosis etc. At autopsy a basophilic adenoma of the pituitary is found in a large proportion of the cases in the literature which I have read. The raised

blood pressure was evident and constant in the reports of seventeen cases confirmed by autopsy and in which the blood pressure was recorded.^{3, 12, 23, 33, 35, 38, 88, 98, 110, 126, 127, 130, 131, 141, 150, 151} Some of the literature I have not been able to read^{16, 58, 142} etc. and in numerous published cases there was no anatomical verification.

Certain improvements which occur when the pituitary is irradiated favor the theory that it is the prime factor of this disease (Cushing, Jamm, Dattner, Wohl and collaborators, Aub, etc.). Even though the basophilic adenoma is not constant (according to Bauer¹³ it was found in only fifteen out of twenty-three cases) its frequency is significant since in general it is a rare condition, Susman¹⁴⁰ finding it in only 3 per cent of the 260 pituitary glands which he examined. In some cases adenoma was not present but there was an increase in the basophilic cells, this is an equivalent pathological state according to Cushing. In discussing the possible part the pituitary might take in the genesis of raised blood pressure he considers that the hypertension might be due (1) to a specific secretion of the adenoma, (2) to stimulation of the pressor secretion of the posterior lobe by the adenoma, (3) to an action through some other gland. Cushing^{38, 39} is inclined to accept the second of the possibilities just mentioned, while Bauer¹³ maintains that elevation of pressure is due to adrenaal hyperactivity brought about by the pituitary adenotropic hormone.

Cushing³⁹ observed that in cases of eclampsia and elevated blood pressure and in certain cases of basophilism with hypertension, there was basophilic cell infiltration of the posterior lobe. This might indicate hyperactivity of this lobe, but, according to Spark,¹²⁷ this morphological appearance has no significance. He made an extensive study of reported cases and sectioned the pituitary in seventy cases of raised blood pressure, in eleven with a previous history of raised blood pressure and in 108 where the blood pressure was normal, in all types of cases a similar basophilic infiltration was found. Also Butt,²⁸ in 200 cases, failed to find any correlation between the degree of basophilic infiltration and the presence of arterial hypertension, arteriosclerosis, eclampsia or obesity. On the other hand an increase in the basophilic cells of the pituitary has been reported in cases of raised blood pressure^{19, 91, 92} and more frequently in adiposity. Kraus⁹¹ found it in 80 per cent of cases of the latter type and believed that the basophilism was secondary to the obesity. In some cases of adrenaal tumor the fact that foci of basophilic cells without adenoma^{18, 100*} have been found in the pituitary

*In these cases it may be supposed that pituitary basophilism was the cause of the adrenaal adenomas which later became malignant.

has suggested the possibility that basophilism may be secondary to overactivity of the adrenal. Finally, Leyton¹⁰¹ found Cushing's syndrome in a case of thymus tumor associated with adrenal hyperplasia.

It is known that the presence of the anterior pituitary is necessary for the development and maintenance of the normal anatomical and functional state of the adrenal cortex.⁷² Hypophysectomy causes the atrophy of the reticular layers and of the internal part of the fascicular layers with preservation or hypertrophy of the glomerular zone, but leaves the medulla unchanged. Adrenotropic extracts of the pituitary may bring about the hypertrophy of the adrenal cortex^{15, 24, 50, 51, 75} etc. and even produce small adenomas^{1, 73} and certain symptoms (adiposity, bone alterations etc.), which Thompson and Cushing¹¹¹ consider similar to those of basophilism. Up to now it has not been observed that they cause a rise in blood pressure.

Bauer¹² attributes the symptoms of Cushing's syndrome to hyperactivity of the adrenal cortex due to an overproduction of the adrenotropic pituitary hormone. He refuses to accept the theory that it originates in the basophilic cells, citing the frequency of basophilism in different circumstances and the fact that Sokolow and Gromow¹⁰⁴ found a cortico-adrenal syndrome with raised blood pressure in a child which was found to have an eosinophile adenoma of the pituitary. The anatomical state of a gland does not give an adequate measure of its function, for this reason a possible overactivity of the pituitary or the adrenal glands cannot be excluded in those cases where no basophilic adenoma or adrenal hypertrophy is found. It would be necessary to measure the amount of hormones secreted into the blood. Bauer¹² further draws attention to the fact that the symptoms of Cushing's syndrome are also those of hyperactivity of the adrenals. In chromaffin tumors of adrenal origin the blood pressure is raised permanently or paroxysmally and in six cases in which the tumor was removed the paroxysms disappeared. It has not been proved that permanent hypertension is due to an excessive secretion of adrenin. Probably cortical overactivity also causes the blood pressure to rise since there are cases of tumors of the adrenal cortex with high blood pressure and hyperglycemia and in some instances removal of the tumor has cured these symptoms. It must also be remembered that in certain cases of Cushing's syndrome the adrenals are normal, although generally they are hypertrophied or adenomatous.

The adrenal symptoms are predominant in the syndrome of basophilism but it cannot be affirmed that the hyperactivity of the adrenals is always of pituitary origin although the large

number of typical and marked cases with basophilic adenoma of the pituitary is suggestive. It can only be suspected that the latter is the primary cause in many cases. It is not yet clear whether the raised blood pressure is due to an excess of adrenal or pituitary hormones or to some other cause since the presence of these hormones in the blood has not yet been confirmed.

THE PITUITARY AND RAISED BLOOD PRESSURE IN THE TOXEMIAS OF PREGNANCY AND IN ECLAMPSIA

Since Hofbauer's work⁶⁶ it has been maintained that eclampsia may be due to a polyglandular disturbance, with an excess of the posterior pituitary lobe secretion predominating. The principal arguments brought forward and some of the objections raised to them are as follows. (1) There is a certain similarity between the symptoms of eclampsia and those which are produced by posterior lobe extract,^{4, 10, 44, 66, 95, 100, 113, 117} etc. (e.g. tendency to edema, raised blood pressure, capillary spasm, convulsions and coma, pulmonary edema, ionic changes, favorable action of narcotics), but there are also definite differences.^{1, 118} (2) There is a certain similarity between the anatomical lesions found in eclampsia (in the liver, kidney etc.) and those provoked by posterior pituitary extract.^{52, 59} However the majority of writers consider these lesions rare and hardly worth mentioning.^{*} (3) The infiltration of the posterior lobe by basophilic cells in eclampsies would cause oversecretion of pituitrin,⁵⁹ but Spark¹²⁷ proved that the basophilic invasion may occur when eclampsia is not present. (4) Dialysis of the serum of eclampsies shows that there is an increase in antidiuretic and blood pressure raising substances,² but this cannot be pituitary posterior lobe secretion (Theobald¹¹⁴). The blood of eclampsies, when injected into the cerebral ventricles, causes oliguria according to Marx.¹⁰⁴ The antidiuretic action, however, has not been confirmed in the careful experiments of Byrom and Wilson⁷ or of Hurwitz and Bullock.⁴¹ (5) The melanophore dilating substance is increased in the blood⁴² and placenta⁴⁹ of eclampsies. Against this are the reports that the blood of eclampsies is common with that of normal or pregnant women possesses the property of neutralizing the effects of certain of the posterior pituitary lobe extracts for example the oxytocic,^{7, 115} etc. the oliguric,²¹ the melanophore dilator¹⁷ and the pressor.^{1, 4}

THE PITUITARY AND OTHER HYPERTENSIONS

An increase of basophilic cells has been seen in the hypophyses of two thirds of the cases of raised blood pressure,¹⁹ but is even more fre-

* For the other literature see H¹ and for the most recent Ohtsuzumacher¹¹ and Scherer.¹¹²

quent in obesity,⁸¹ and has also been observed in other conditions. Spark¹³⁷ declares that the posterior pituitary lobe invasion by basophile cells described by Cushing^{88 89} can exist with equal frequency when there is no raised blood pressure.

Kylin⁸⁷ believes that the anterior pituitary lobe is an essential factor in hypertension, because the general and metabolic symptoms are exactly opposite to those of pituitary insufficiency. Pal,¹¹⁶ and Merle and his collaborators¹⁰⁷ also believe in the pituitary theory and Drouet¹⁴⁸ describes improvement in certain cases of raised blood pressure due to irradiation of the pituitary. The cerebrospinal fluid of patients suffering from raised blood pressure only occasionally contains "minute traces of pituitrin",⁷⁹ so an overactivity of the posterior pituitary lobe does not seem to be an etiological factor in the disease. Moehlig¹⁰⁹ has produced arteriosclerosis in rabbits, by submitting them to a diet rich in fats and cholesterol combined with treatment with pituitrin. Volhard¹⁴⁸ has shown that the raised blood pressure due to ligation of the renal artery is produced both in normal and hypophysectomized dogs.

PITUITARY, DIENCEPHALON AND HYPERTENSION

It has been known for some time* that the principal vasomotor centres are in the medulla. Section of the brain stem above the pons does not modify the level of the blood pressure or the vasomotor reflexes and reactions^{25 26 65 86 138, 139} etc. in acute experiments.

The stimulation of the posterior ventral part of the hypothalamus causes a marked rise of blood pressure,^{17 77 82 84 86 124 149} even in the absence of the pituitary and adrenals (Karplus and Kriegl, confirmed in our Institute). When the adrenals are present there is also a marked secretion of adrenin, itself capable of raising the blood pressure⁷⁷ and the blood sugar.⁸² The melanophore dilating substance in the cerebrospinal fluid is also increased.⁸⁷ Ergotamine or the extirpation of the sympathetic chain and the splanchnics⁸² suppresses the rise in blood pressure. Leiter and Grinker¹⁰¹ affirm that the rise in blood pressure occurs only when there are muscular or respiratory disturbances, but de Jaegher and Van Bogaert⁸² have shown that it may be raised both by mechanical and chemical stimuli which do not evoke muscular activity. According to Hoff and Urban⁸⁷ lesions of the mammillary bodies may cause a delayed rise in blood pressure some months after the operation.

It has not been proved that the pituitary takes part in the rise in blood pressure produced by cisternal injection of kaolin or other colloids.^{80 81 90} Pituitrin causes a rise of blood pressure if it is injected into the cerebrospinal

canal^{74 80} or the cistern.^{81 82} If, however, it is injected into the ventricles there is either a fall in blood pressure followed by a rise⁸⁷ or no effect at all.⁸³

GENERAL SUMMARY

The posterior pituitary lobe contains vasoconstrictor substances, which in amphibians play a very important rôle in the maintenance of the blood pressure and arterial and capillary tone. Small quantities of similar substances exist in the principal lobe of the toad, but removal of this lobe causes a lowering of the blood pressure only after asthenia has developed. In the rat, dog and man pituitary insufficiency is accompanied by lowered blood pressure, it is not clear whether this is due to lack of one or both lobes, but it seems more particularly due to lack of the anterior lobe (central or peripheral vascular asthenia).

The existence of raised blood pressure in acromegaly has not been well established, since the blood pressure is frequently normal in these cases. On the other hand hypertension is a constant and prominent symptom in the pituitary basophilism syndrome of Cushing, though whether this is due to pituitary or adenal hypersecretion or to a secondary or associated factor, is not yet clear.

The evidence put forward to demonstrate that hyperactivity of the posterior pituitary lobe is the causal factor in eclampsia and in essential hypertension is contradictory and inconclusive.

In contradistinction to the medulla the diencephalon is not essential for the maintenance of blood pressure in acute experiments, nor has it been proved that increase in blood pressure due to lesions or stimulation of this region is accompanied by hypersecretion of the posterior pituitary.

MERCURIN SUPPOSITORIES AS A DIURETIC IN THE TREATMENT OF EDEMA*

BY MARSHALL N. FULTON, M.D.†

IN the treatment of edema, particularly chronic or recurrent edema diuretic drugs frequently are of great service. Of these the organic mercurial salts have come to be used extensively because of their effectiveness in increasing urine output and their relative freedom from toxic effects. Salyrgan (merisalyl) enjoys a widespread popularity and has been found to be effective even when given repeatedly over a long period of time.^{1,2} During the past few years another preparation, mercupurin introduced in Europe under the name of novurit, combining both a mercurial salt and theophylline, has been given enthusiastic recognition.^{3,4} The disadvantages in the use of these drugs are (1) that they must be given either by intravenous or intramuscular injection (2) that by the former route they are liable to injure the vein or surrounding tissues and by intramuscular administration are irritating and painful and (3) that their repeated use requires frequent attendance of doctor to patient or of patient to doctor or clinic, which necessity often curtails their employment. If either drug or any other preparation equally effective could be administered by the patient, himself under supervision, there would be a saving both in time and money and added convenience of no little measure.

It has been shown in certain European clinics that the mercurial component of mercupurin, the sodium salt of trimethylcyclopentane-dicarboxylic acid-methoxy mercuric hydroxide alkylamide is effective as a diuretic when administered by rectum in suppository form.^{5,7,8} This preparation has recently been introduced in this country under the name of mercurin suppositories. During the past eight months at the Peter Bent Brigham Hospital we have had the opportunity of using mercurin suppositories in twenty-five patients with edema.† They have been found to be an effective and safe diuretic, producing results comparable with those obtained by

the intravenous injection of salyrgan or mercupurin. These results are published with the feeling that this preparation offers a distinct advance in diuretic therapy, particularly in the convenience it affords to both doctor and patient.

PLAN OF TREATMENT

All but five of the patients with whom this report deals had cardiac failure with edema. Most of them were observed for a time at bed rest on the hospital wards. Following a period of several days' observation to allow for adequate digitalization or a spontaneous diuresis, they were given one gram of ammonium chloride three or four times a day. This therapy, introduced by Keith and his associates⁹, has been shown to enhance the action of mercurial diuretics by the mild degree of acidosis which it produces.¹⁰ After two to four days of this régime the patients were given the suppositories usually the first thing in the morning following a cleansing enema. Use of the suppositories or other diuretics was repeated at intervals of four to six days, the patients, meanwhile, continuing on a daily dosage of three or four grams of ammonium chloride.

Each suppository, made of cocoa butter base, contains 500 milligrams of the mercurial salt of mercupurin ($C_{14}H_{24}O_5NHgNa$) without any added theophylline. This is approximately five times the amount of mercury contained in one cc of mercupurin or salyrgan.

RESULTS

The diuretic response to the suppositories was very satisfactory comparing favorably with that observed after intravenous administration of mercurial salts. The increased urine flow began in one to three hours after the suppository was given and was passed, as a rule, by the end of twelve hours, so that the patients were not kept awake the following night voiding urine. Occasionally the increased urine flow lasted twenty-four hours or longer. That the absorption of the material by the rectal mucosa may occur very promptly was indicated by one patient who had a bowel movement twenty minutes after insertion of the suppository, yet who

‡We wish to express our thanks to the Campbell Products Inc., 79 Madison Avenue, New York, N. Y., for the suppositories used in this work.

passed three liters of urine in the next twenty-four hours. In only one instance did a patient fail to have a diuresis with the suppositories after responding satisfactorily to other diuretics. Conversely, both suppositories and parenterally administered mercurials failed to induce a significant diuresis in six of the patients on whom they were tried. A few individuals complained of slight rectal irritation and burning for fifteen to thirty minutes after the insertion of the suppository, more stoical ones made no

ures do not afford a close measure of the comparative diuretic potency of these several preparations inasmuch as the first diuretic given on admission to the hospital often calls forth a much greater urine excretion than those given subsequently. The urine output in edematous patients is influenced markedly, among other things, by the extent of edema present at the time the diuretic is given. The figures do show, however, that the urine output observed after mercurial suppositories com-

Mercurial instead of Salyrgan given

†Salyrgan given intravenously

Figure 1 parentheses do not show number of times preparation was given.

Patient F. P. had subacute phthisis in the nephrotic stage. Patient H. M. and M. L. had cirrhosis of the liver. All the other patients had either chronic myocarditis or chronic valvular heart disease.

complaint. One patient occasionally passed mucus in the stools on the day the suppository was administered. In no instance were toxic effects observed from use of this form of medication as manifested either in the patient's condition or by changes in his urine or kidney function tests. The suppositories have been used by patients at home with results quite as satisfactory as those observed in the hospital.

The results are indicated in table 1 which shows the maximum and average twenty-four hour urine volumes observed on the days the suppositories were used. For comparison, figures are given to show the urine volumes when Salyrgan or mercurial were administered intravenously, to the same patients. These fig-

ures compared very favorably with that following Salyrgan or mercurial given intravenously.

The response of two patients is shown in charts 1 and 2.

Chart 1 (Patient M. McC) is from the record of a thirty-eight year old single female with chronic rheumatic valvular disease (aortic and mitral stenosis and insufficiency possibly tricuspid insufficiency). She began having severe dyspnea in 1933 and developed ascites which first required tapping in July of that year. Until the time of the first admission shown in the chart (September 1935) she had ten abdominal paracenteses for recurring ascites, the last three being in April June and August 1935. During 1935 she found it necessary in addition to the hospital admissions for tapping to attend the outpatient clinic some thirty-five times for intravenous injection of diuretics. Theoclu-

given at home caused nausea and vomiting. Urea was only moderately successful in increasing the urine output. With the diureses afforded by the medication, as shown in the chart, it was possible for the patient to go from October 25 until mid January without tapping. Suppositories, administered by the patient at home during December and January, produced twenty-four hour urine volumes varying from 3100 to 4300 cc.

CHART 1 (Patient M McC) Fluid intake and urine output during two hospital admissions between September 16 and December 12 and urine output following mercurin suppositories taken at home. In this and chart 2 circles represent the fluid intake, dots the urine output. MS = mercurin suppository. S = salyrgan given intravenously. SS = suppository containing residue after evaporation of 2 cc of salyrgan. Th 2 = two doses of theocin 0.3 Gm each.

Chart 2 (Patient N G) shows the course during two hospital admissions of a forty-four year old male patient with chronic myocarditis and hypertension. In September, 1933, he had an attack of coronary thrombosis. Subsequent to this he had

Patient E P (table 1) with the so called nephrosis syndrome, having normal excretion of phthalein and no nitrogen retention, was given mercurin suppositories fourteen times during the course of four months with resulting diureses ranging from 1500 to 4000 cc in twenty-four hours. During this time there was no evidence of added kidney damage from the mercurin administered and edema, while not abolished, was satisfactorily controlled. This case illustrates that certain selected patients with edema of renal origin notably those with subacute or chronic nephritis who show normal ability in excreting phenolsulphonphthalein and nitrogen, may be given mercurial diuretics with safety.

Experience with the patient L W during the past ten months indicates the advantages incident to the use of the suppositories in patients with persistent edema who are well enough to be ambulatory. This patient, a forty-five year old Negro, has chronic myocarditis with recurrent ascites which has necessitated frequent abdominal taps, the last ones being done in June and September, 1935. Between June and November of that year, he made weekly trips to the out-patient clinic for the intramuscular injection of a mercurial diuretic. There was no other indication for such frequent visits. In November he was tried with mercurin suppositories with satisfactory results. For the past three months he has been able to extend the interval between visits to four weeks, taking a mercurin suppository each week at home with continued good response. During these three months his weight has remained constant. There have been no changes either in the urine examination or in the condition of the patient. Naturally, he prefers this form of therapy inasmuch as it abolishes the necessity of his frequent trips to the hospital.

The four patients having ascites and edema with cirrhosis of the liver, on whom the suppositories were tried, failed to respond with satisfactory diuresis. Only two of these (H M and M L) are noted in table 1. This is in

CHART 2 (Patient N G) Fluid intake and urine output during two hospital admissions between October 5 1935 and February 4 1936

two admissions to the hospital because of angina pectoris and cardiac failure before total thyroidectomy was done in March, 1935. He was not greatly improved by this procedure, and on his fourth admission in October, 1935 (the first one shown in the chart) he exhibited marked cardiac failure with hydrothorax and edema of the extremities. He was, of course, given digitalis and ammonium chloride throughout the two admissions shown in the chart. Though it was not possible to rid the patient of his edema or to reduce his weight more than 11.2 kilograms, he was kept from the accumulation of massive anasarca by the repeated diureses. With the suppositories twenty-four hour urine volumes between 3000 and 4500 cc were obtained repeatedly.

keeping with the general experience at this hospital, that diuretics are much less effective in removing ascitic and edema fluid in patients with hepatic cirrhosis than in those with cardiac failure.¹¹

COMMENT

The obvious advantage of this form of diuretic therapy is its simplicity and ease of administration. It does away with the clinical as well as the economic disadvantages of giving diuretics intravenously and intramuscularly. The same may be said of any of the diuretics given by

mouth, such as urea, theocin, metaphyllin or other drugs of the xanthine group. These other preparations, however, are not always well tolerated by patients, and do not effect in general so satisfactory an increase in urine output as that resulting from the mercurin suppositories. The latter, thus far in our experience, have produced diureses quite comparable to those obtained by parenterally administered mercurial salts.

It has been our experience with the suppositories as with mercupurin and salyrgan, that the patients excrete more urine if an acid forming salt such as ammonium chloride is given in daily dosage of three or four grms. either continuously or with occasional rest periods of several days between "courses". The suppositories have been repeated at intervals of four to six days according to the extent or persistence of edema.

The advantages obtaining from this method of administering diuretics afford a definite advance in the treatment of edema by diuretic drugs.

SUMMARY

Mercurin suppositories containing 500 milli-grams of the mercurial salt of mercupurin, administered by rectum have been found to cause diureses in edematous patients comparable with those observed after mercurial salts given intravenously.

No significant untoward or toxic effects occurred in twenty-five patients receiving from one to fifteen suppositories.

The simplicity of administration makes this form of therapy very suitable in the treatment of patients with edema in whom the use of diuretics is indicated.

VERMONT STATE MEDICAL SOCIETY

THE BIOPSYCHIC APPROACH TO DISEASES OF THE MIND ITS DEPENDENCE ON NEUROLOGY AND GENERAL MEDICINE*

BY FOSTER KENNEDY, M.D.†

NEUROPSYCHIATRY by its very nature must pervade all medicine. Neurology must rest upon it, and must be the base of psychiatry. We who study these things must concern ourselves with the general field. You remember when Peter rested on the roof top he saw a great sheet let down from Heaven full of all manner of creeping and crawling things. Shrinking from them he heard a voice from on high saying "Call nothing that I have created common or unclean."

In the past century neurologists were busy collecting, classifying and, as their often unappreciative colleagues would say, "labeling" specimens of neural disorders. Even today many physicians point at us an unwitting finger thinking us an academic lot, full of wise saws but in the main signifying nothing. This view is long outgrown far behind the realities of our employment. We have viewed and learned the flora on the ground's surface, tabulated and

brought them into the scheme of law. Now is the task of digging into the ground to find the roots from which plants spring and of analyzing the soil—often heavy and seemingly unprofitable labor, but work which is the very stuff of medicine and on which will one day be established a true pathology of mind.

May we here examine a little the detail of this pretentious statement? For example, think of the rôle of focal infections in the production often quickly, often after long intervals of degeneration in the central nervous system. Abscessed teeth and chronic sepsis of the tonsils by perineural lymphogenous infections cause cervical spinal arachnoiditis with cord compression and slowly progressive paraplegia. Caruncle of the neck by lighting an almost instantaneous fire may cause an explosion in the upper spinal segments with transverse myelitis and quadriplegia. Diphtheritic sores of the hand have been shown to cause radiculitis and spinal paralysis of the affected arm while the same diphtheritic sores on the thigh throughout the British Forces in Mesopotamia gave rise to cauda equina neuritis with double

dropped feet and paralysis of the sphincters. Kimmie Wilson has shown the part played by chronic lead poisoning in painters and cable layers in the later production of amyotrophic lateral sclerosis. If one neural poison can cause central cell degeneration in this manner the same road of invasion is open to others whose nature still lies hidden from us.

Lately a woman was seen by us who gave a history of recurrent herpes zoster in the left second and third lumbar root skin areas of the left upper thigh. The painful eruption had appeared regularly for sixteen months in the first days of each menstrual period. She had consulted many physicians of the skin with slight symptomatic success. The clue to her condition was the discovery of an infected Bartholin cyst in the left labium which aggravated at the period, caused an ascending inflammation of the appropriate roots and posterior spinal ganglia.

Again a man was seen who had extensive anterior horn muscular atrophy of the legs with fibrillary twitching, usually thought characteristic of progressive muscular atrophy. The absence of any signs of involvement of the cervical segments, however, caused us to suspect the existence of a local infecting focus. The cure of a chronic prostatic abscess, in this case, resulted in recovery of function in the lower spinal segments.

Last year a soldier had eight upper teeth removed at one time under local anesthesia. Three days later he began to have severe neck pains and occipital headache and, in two weeks, he died of meningitis. The road for bacterial invasion of the brain membranes had been opened through overconfidence in modern dentistry applied to infected tissues.

One may point out the dependence of some spinal cord degenerations on long standing achylia gastrica which, in its turn, may depend upon a chronic cholecystitis.

A dozen years ago a violent epidemic of poliomyelitis with many scores of fatalities was traced to streptococcal milk. The dependence of other inexplicable forms of neuritides is often found in nutritional deficiency, not due to inadequate diet but to inadequate assimilation through deterioration of function in the mucous membranes of the alimentary canal.

There is no need to pile Pelion on Ossa, we must realize that the causes of neural degenerations lie often in infections of other tissues. Within the lifetime of all here paresis and tabes have been proved to be caused by lues and only by lues, but most of the older men as students were instructed that these two nervous diseases might come from overwork and exposure—presumably to the winds of Heaven! I was told as a student that paralysis agitans was "a neuro-

sis" without organic basis. We know now its cellular pathology and much of its infective origin. Asthma was to me at college akin to the vapors of a still earlier day. Now we understand that its allergic etiology is due in great part to individual sensitiveness to specific proteins which may cause some forms of palsy, blindness, and various obscure cerebral illnesses.

So, we neurologists live in no ivory tower. We scurry over and delve in the fields of internal medicine and must also try to throw searchlights through the tenebrous fog of endocrinological fact and fable. So, too, we must deal with the aberrations of all the special senses. We must try to bare the causes of many cases of blindness, of discrete losses of vision, of diplopia and, often enough, of simulated disease. We must try to give a reason for subjective visual phenomena, like visual fits or the more complex hallucinations of men and things associated with disordered function in the temporal sphenoidal lobe. We must know enough about sinus disease to distinguish between the pain caused by osteitis of the floor of an antrum and that of trigeminal neuralgia and between the localized headache due to pus in a sphenoidal sinus and a unilateral migraine. We neurologists must examine the ears ourselves and later secure skilled aid from the expert. We have to decide the significance of subjective ear noises and the significance of islands of lost hearing, to appraise labyrinthine efficiency and distinguish errors in semicircular canal mechanism from those of the cerebellar system. Errors in respiratory rhythm and palsies of the vocal cords, together with bulbar palsies and hysterical aphonias give us a link with the laryngologist. Thus the senses of taste, touch and smell, and the vagaries of speech all bring grist to our mill and we must grind thoroughly if we would make good bread.

We cannot busy ourselves with the spinal cord without acquaintance with its bony covering, nor can we deal with paralyzed members with no concern for the resources of the orthopedic surgeon in their cure. At times we can elucidate the cause of sciatic pain as being due to a tumor of the epiconus, not easily susceptible to spinal fusion, and aid by the diagnosis of dystonia musculorum in the orthopedic problem of the resultant disordered joint.

The palsies of the sphincters and the failure of the sexual reflex bring us into alliance and understanding with the genitourinary surgeon, but it is in the great problem of incurable pain that we can perhaps be of most assistance. In operable pelvic cancer, prostatic or uterine, may be made somewhat bearable by the operation of choirotomy, the division in the upper dorsal region of the tracts carrying pain impulses to the brain and consciousness. This operation in

proper hands, is no more arduous to the patient than is an exploratory laparotomy or an appendectomy, it causes no motor palsy, no essential sensory loss, merely a transient sphincter disturbance and will secure the patient from most of the unpleasant features of morphine life. There is nothing to be said for the expectant treatment of bladder or womb cancer. When the diagnosis has been established and local treatment exhausted chordotomy should be done before morphine addiction has occurred.

All the specific fevers have their nervous concomitants, paralyses due to cerebral thromboses, neuritis, deliria and psychoses. These latter, mark you are the outcome of infection and fever. Is it not strange to us that a patient with pneumonia or typhus who harassed by delusions of imminent destruction throws himself from a window, is classified as delirious from fever, while the same psychic situation with no obvious intoxication may be called paranoia, the organic pathology of which most psychiatrists deny? One patient is said to have a disease of the body, the other a disease of the mind. This is at once loose and dogmatic thinking. We must reduce a pathology of mental disease through medicine the effort to do so through philosophy and psychology has failed. They are useful till our knowledge of the body will have grown to larger stature. In therapeutics they deal well enough with symptoms but a sharper sword is today being forged by medicine to deal with the nature of mental illness itself.

Often one hears a plea from the psychologist for the consideration of the human animal as a whole. We have often heard physiologists speaking of the cerebrum, the cortex, acting as a whole. I have never been quite able to understand clearly what is meant by the physiologist when he speaks of the cortex acting as a whole. Head uses the phrase in his writings. I have always thought it a very confusing term, but I think I do understand or approximate to understanding what is meant by a human being acting as a whole in that the metazoan, multicellular animal functions in each act as uniquely in as unified a manner as does the unicellular animal. Each behavior, each act of behavior, is the resultant of the forces that are in the organism so that I think one may properly speak of the human being as acting as a whole which is far from being the same as feeling or thinking as a whole. Many lately have spoken rather adversely of Freud's philosophy. Freud's theory as being a purely motivistic relation of human behavior. Now unfortunately, those who speak decidedly on any side in this rather amorphous world get the reputation of being prejudiced.

Our antagonism if it can be called antagonism

—and it is only criticism—to psychoanalysis is not that it is wrong but that it is only true in part. It is one angle of view only. Our mind symbolizes anything we see we see but one aspect at a time and that first and clearest that appeals to the consciousness of the observer. The important thing is to try to have more than one angle of vision, but the psychoanalyst seems to see like Polyphemus, with but a single eye and one cannot but feel that there is a certain belief in their circles that they have absorbed psychiatry. The psychoanalyst feels that only he is truly a psychiatrist and that unless one is a psychoanalyst one is not a psychiatrist, and that he who is not for them is against them. This is on the banner of all religions. They suggest that one has no right or power to have a notion or an idea of human personality in other terms than theirs. Shakespeare was not a psychoanalyst. Voltaire was not a psychoanalyst, George Moore and Thomas Hardy were not psychoanalysts, but I venture to say that these men knew more of the human spirit and the motivistic phenomena that prevail in the human heart than most of Freud's disciples. The great artists are perhaps the greatest of all psychiatrists. Their understanding may be better than our knowledge. So I feel the Freudian contribution to be this: Freud has demonstrated that there is a phylogeny of personality. By that I mean that each of us is a microcosm of our race. From the egg to death we pass through stages in our body at least similar to those through which the whole race has passed. Freud has made it clear that in our emotion, in our striving in the preponderance of this instinct over that at different periods of our lives we have a like phylogeny of personality that the child is a savage that its sexual instinct emerges by gradual progression from a preoccupation with one orifice to a preoccupation with another. That is a true contribution to knowledge. Freud himself however, has lately said that he is not sure whether it is a contribution to therapeutics but at least it does make it clear how our instincts developed inside the microcosm of each man's body. We have vestigial remains like gillslits and others like satological tropisms, but we cannot describe the total body in terms of the one or the total personality in terms of the other.

This analysis of behavior has been nevertheless, a great compensation against the materialism and dogma of the "cellular" epoch which perforce evolved in the nineteenth century. However, if we are to think solely in terms of this reversion to dualism this ecclesiastical view of man which has beset our minds and lamed our thoughts for two thousand years if we are to think that such patterning and clocking constitute the whole of psychiatry then

dropped feet and paralysis of the sphincters Kinnier Wilson has shown the part played by chronic lead poisoning in painters and cable layers in the later production of ankyrotrophic lateral sclerosis. If one neural poison can cause central cell degeneration in this manner the same road of invasion is open to others whose nature still lies hidden from us.

Lately a woman was seen by us who gave a history of recurrent herpes zoster in the left second and third lumbar root skin areas of the left upper thigh. CASE 22221

PRESENTATION OF CASE

A seventy seven year old fisherman was admitted to a convalescent hospital complaining of swelling of the lower extremities.

Three weeks previous to admission he first noted some weakness which was associated with moderate difficulty in breathing. There was also slight dizziness and a gradually progressive edema of both feet and legs.

Thirty five years prior to his entry the patient had had a carcinoma of the lower lip excised. One year later he returned with an ulcer of the lip which was thought to be a recurrence but which on section showed no evidence of malignancy. Twenty years before entry he was in the Out Patient Department with a generalized skin rash, sores on his tongue and lips, and was found to have a strongly positive Wassermann test. Nine years later the Wassermann was still strongly positive. Six years before his final entry he returned to the hospital with a complaint of pain in the right side of his abdomen of three weeks' duration associated with nausea, vomiting and occasional shooting pains radiating down into his genitalia and both legs. A huge mass was palpable in his right upper quadrant and shortly thereafter a transperitoneal nephrectomy for hypernephroma was done. At operation it was noted that the glands in the region of the renal pedicle were involved but were inextricable.

Physical examination showed a well-developed and nourished, pallid elderly man. The lower lip was contracted and scarred. The heart sounds were distant and muffled in character. No murmurs were audible. The blood pressure was 140/80. The radial vessels were tortuous and sclerotic. The lungs were clear. There was a small ventral hernia noted. The scars of the two previous operations were not remarkable. There was tenderness in the right upper quadrant but no mass was palpable. There was pitting edema of both lower extremities and a large exostosis was felt protruding from the surgical neck of the humerus.

Examination of the urine showed a specific gravity of 1.014 with a slight trace of albumin. The sediment contained 30 white blood cells per

high power field. The blood showed a red cell count of 3,000,000 with a hemoglobin of 39 per cent. The white cell count was 4,400, 68 per cent polymorphonuclears. A blood Wassermann test was negative.

The patient remained in the hospital for six months, during which time his edema persisted despite varied therapeutic measures. His temperature ranged between 98° and 99° and his pulse between 60 and 80. A hypochromic anemia which had been noted was improved by the administration of iron and liver. His general condition improved to such a point that during the sixth month he was allowed to return to his home for several one week vacations. His edema, however, remained little improved despite digitalization. During the seventh month vague complaints of dyspepsia led to a gastrointestinal x-ray. The films showed a large polypoid filling defect in the anterior wall of the stomach measuring about two inches in diameter. Thereafter his condition remained essentially unchanged although he had occasional nocturnal epigastric discomfort which was relieved by alkalies. During the tenth hospital month he developed chills, a temperature of 103° and pain in the right side of his abdomen. Examination of the chest was recorded as being negative. There was some urinary frequency and burning dysuria. He was given fluids intravenously. A urine examination showed no change from the admission specimen. Thereafter he became progressively weaker, his temperature ranged between 100° and 103° and the pain in his right upper abdomen persisted. He died about ten and a half months after entry, two weeks after the onset of his acute symptoms.

DIFFERENTIAL DIAGNOSIS

DR. FLETCHER H. COLBY. It seems apparent that neoplastic malignant disease is the chief consideration in this patient. This individual had cancers of two parts of the body that of the lip thirty five years before entry and that of the kidney six years before. The chief point to be determined, it seems to me, is whether the gastric tumor which was discovered three months before death is related to either of these other two neoplasms.

The high lights in the history are these: an elderly man with progressive and persistent edema of the lower extremities, weakness and anemia and the obvious presence of a large tumor of the stomach. There is no evidence of marked circulatory weakness to account for the edema. It is limited to the lower extremities. It did not recede with long periods of rest. Likewise there is no evidence of marked renal impairment although one kidney was removed six years before, but the description of the terminal illness does not suggest uremia. The edema then would appear to be due to obstruction to

the return circulation in the large vessels. The cancer of the lip is dead and buried. That was thirty-five years ago and there has been no recurrence since. I do not believe it needs to be considered. A large malignant renal neoplasm was removed from this patient six years before. My compliments to the surgeon who did it. A transperitoneal nephrectomy in the first place, in the presence of such a large mass, is a difficult procedure. It was noted by the surgeon at that time that there were enlarged lymph nodes, presumably tumor-laden lymph nodes, in the region of the right renal pedicle. These probably were situated on the large vessels and it is reasonable to suppose that those large lymph nodes continued to grow larger and cause obstruction to or possible actual involvement of the large veins. Secondary tumor deposits from certain of the renal tumors grow very slowly. It is not uncommon to have recurrences five to twenty or more years after the removal of these malignant tumors called hypernephromas. They are all probably species of cancer. They most frequently, as you probably all know, metastasize to the lungs and to the bones. The exostosis of the humerus might be a secondary deposit, I do not know. There is only that to go on and frequently these tumors metastasize to bones and by choice to the long bones. There is no evidence of involvement of the lungs although such may easily be present.

Is the gastric tumor primary or secondary to the renal growth? Metastases from hypernephromas can involve any part of the body. It is unusual for them to involve the stomach. This might be an extension from the tumor in the region of the large vessels, actual tumor extension to the stomach, but if that were true I think we would expect to find a large palpable mass in the upper abdomen. Such was not present. The gastric tumor is described as polypoid in character. That sounds more like a tumor which came from the stomach itself than a metastatic nodule of tumor tissue or tumor that has extended to the stomach and involved it. I do not believe this individual is entirely free of his renal growth. It is reasonable that these lymph nodes which were discovered at the time of operation six years before have continued to grow larger and have caused obstruction to the large vessels either by pressure or by actual tumor extension. I believe that the gastric neoplasm is an independent one. That makes this individual have three different cancers. I think his liver probably is involved by the cancer and that would probably account for the pain in the right upper abdomen. I think in all likelihood he died of terminal pneumonia.

DR. TRACY B. MALLORY. Dr. O'Neil, you operated on this man. Will you tell us about it, please?

DR. RICHARD O'NEIL. I remember this patient. I saw him in consultation with the surgical service and at that time he had a large mass in the right upper quadrant. As I remember, there was no history of hematuria. When it is present of course it is a very significant element in renal diagnosis but it is not by any means constant, and it is not uncommon to see a renal tumor that does not have hematuria. Cystoscopy and pyelogram were made and were typical of renal tumor, and a transperitoneal nephrectomy was done. Incidentally, it is interesting to note that in looking over cases reported by Dr. Smith that the first time a pyelographic diagnosis of renal tumor was made in this hospital was in 1916, which seems extraordinary because pyelograms were being made some time before that.

The operation on this man was done under spinal anesthesia and the tumor removed transperitoneally, which is the best route for these large renal tumors. You can get better access to the pedicle. It was noted he had some glands which were not removed because they were adherent to the great vessels. The extraordinary thing is that this man had gone five years after an incomplete operation and had no deep x-ray therapy. He was seen by Dr. Simmons who suggested that he should have x-ray treatment. Dr. Holmes saw him and advised against it unless the man could come in and have a regular course of treatment, which he did not do.

In a series of twenty-six operative cases of hypernephroma reported from this hospital in 1925, one lived ten years, two eight years, one seven years, and one five years. In a series of thirty-four cases not operated on, the duration of life from the first symptom was in one case seven years, one five years, and on four years. So apparently some do as well without operation as with it. In a series reported by Dr. Hyman of New York, of forty-two cases, nine per cent lived five years, twenty per cent lived four years and twenty-six per cent lived three years. In another series of twenty-five cases all died within seven years. In another series of Berg of Norway, of thirty-seven cases seven lived five years. In these series the time of the appearance of the first symptom to the time of operation varies greatly—one case had hematuria for eleven years. He was operated on and lived for nine months. In contrast to this it might be interesting to say that I had a case four years ago in the Baker, a man thirty-two years old who had hematuria for one day only. He consulted his own physician that night. I cystoscoped him the next morning. At that time there was no hematuria, so a bilateral pyelogram was made which demonstrated a renal tumor. That is, the diagnosis was made within

twenty-four hours of the first occurrence of the symptom which is very unusual. He had nephrectomy four days later. That is about as quick as you can do it. He was all right a year later.

I think in this case as Dr. Colby said that there were two different types of malignancy present but that the renal condition has something to do with his death.

Dr. MALLORY. During the last two years of this patient's illness he was followed, not in this hospital but in the Chelsea Marine Hospital. Dr. Dearing will tell us their impression.

Dr. W. PALMER DEARING. As we saw him during this period of nine or ten months the striking thing was the one Dr. Colby pointed out, the edema of the lower extremities which continued to be so intractable. It did improve as the anemia was treated and did improve a little with his digitalization, but at the same time there was no definite evidence of cardiac decompensation.

The other thing about his course was that two or three times he would flare up with febrile attacks for a few days and complain more of abdominal pain, then would get better. At no time could anything definite be felt in his abdomen though he was constantly tender in the right upper quadrant. When he finally died we felt that he probably had some infected metastases in the liver from the gastric tumor and a question arose as to what the old tumor that had been incompletely removed was doing, but we felt as Dr. Colby did that the stomach tumor was something different, another neoplasm.

CLINICAL DIAGNOSES

Carcinoma of the stomach
Hepatic abscess.
Recurrence of hypernephroma?
Chronic myocarditis.
Exostosis of the right humerus.

DR. FLETCHER H. COLBY'S DIAGNOSES

Carcinoma of the stomach
Recurrent carcinoma of the kidney with metastasis to the liver

ANATOMIC DIAGNOSES

(Renal cell adenocarcinoma, right kidney)
Operative scar. Nephrectomy right
Recurrence of the renal cell adenocarcinoma at the operative site with extension along the right spermatic vessels, the right renal vein and inferior vena cava
Hepatic abscess.
Pulmonary abscess
Pulmonary edema, bilateral
Carcinoma of the stomach
Multiple gastric polyps
Pleuritis chronic fibrous bilateral

Prostatic hyperplasia.
Trabeculation of the bladder
Osteoarthritis hypertrophic
Exostosis of the right humerus
Ventral hernia
Decubitus ulcers
(Syphilis)
Operative scar. Excision of epidermoid carcinoma of the lip

PATHOLOGIC DISCUSSION

Dr. MALLORY. The autopsy showed very close to what was predicted. He had a local recurrence of his hypernephroma at the site of the original incision and this tumor, as is so characteristic of hypernephromas as a group, had directly invaded the renal vein had grown backward down the spermatic vein had grown into the vena cava and reached nearly up to the portion of the vena cava which passes through the liver. So that his edema was undoubtedly explained primarily on the physical basis of a tumor thrombus almost completely plugging the vena cava.

The stomach proved very interesting. It showed three separate polypoid tumors, two rather small ones along the lesser curvature apparently not visualized by x-ray which histologically were perfectly benign polyps, and a large one on the anterior surface near the greater curvature. Microscopically the major part of the large polyp closely resembled the two small ones, and appeared benign in character. There was one definite focus of malignant degeneration however such as we see from time to time in tumors of the stomach that evidently start as benign lesions.

The liver showed a fair-sized abscess in the right lobe with no evidence that it was connected in any way with the tumor. It was about six or seven centimeters in diameter and there was a very small metastatic abscess in the lung half a centimeter in diameter which had nothing to do with his death. I should think death was probably due as much to sepsis from the liver abscess as any other single thing.

I think the case is interesting in pointing out one of the fallacies of the naïve era of medical statistics. It used to be taught that multiple cancers were a great rarity. The obvious reason for that is of course that the great majority of cancer patients died within a relatively short period from the first cancer that they developed and consequently very few of them lived long enough to have a chance to develop a second cancer. When adequate statistical correlations were made it has been possible to show us Dr. Lund and various other people have done that an individual who has had one cancer stands a very much better chance to develop second cancer than the laws of chance

would allow There is undoubtedly such a thing as a tendency to neoplastic growth This man had three separate malignant neoplasms The lesion in the humerus turned out to be a benign exostosis and I think it is rather questionable whether that can be brought into the same category, but I feel reasonably sure if he had been able to live five years more he would have shown still other separate distinct cancers

DR O'NEIL Any evidence of bone metastases?

DR MALLORY Nothing that we found There is one point not mentioned in the physical examination that might have been a help to Dr Colby There was bilateral varicocele which would have been additional evidence in favor of thrombosis

DR GEORGE W HOLMES What about his liver abscess?

DR MALLORY We found nothing to suggest the origin

CASE 22222

PRESENTATION OF CASE

A sixty-nine year old white housekeeper was admitted complaining of bleeding from the rectum

The patient stated that for a number of years she had had a "delicate stomach" which was relieved by four sinus operations, the last of which was performed seven years ago She remained comparatively well until about six months before entry, when she began to have vague colicky pains occasionally on one side and then on the other side of the abdomen These pains were associated with borborygmus, gaseous eructation and the passage of flatus For the last two months these attacks occurred several times a week without relation to meals and were not relieved by bowel movements Her bowel habits were unchanged but the stools, although not diarrhetic were definitely looser than previously and were occasionally dark in color Four weeks prior to admission she began to have gnawing epigastric pain which was relieved by food ingestion Her appetite was increased but only for lettuce and such foods More substantial material seemed to lie heavily in her stomach There was no vomiting Three days before coming to the hospital she passed about a pint of dark blood by rectum Subsequently she passed similar material on two occasions during that day She felt weak and on the day of entry began to vomit She thought that she had lost some weight

Physical examination showed a pale, thin, feeble, sick-looking woman suffering from nausea and vomiting during the examination Slight tenderness was elicited over both maxillary sin-

uses The mucous membranes were pallid The heart was not enlarged and a soft systolic murmur was audible at the apex The blood pressure was 160/80 The lungs were clear The lower midabdomen was full and there was elastic balloon-like resistance in the right lower quadrant To the right of the umbilicus there was a firm, slightly tender rounded mass, about four centimeters in diameter which seemed to move slightly with inspiration Peristaltic sounds were slightly increased No further findings were noted

The temperature was 99°, the pulse 100 The respirations were 22

Examination of the urine showed a specific gravity of 1.020 and a slight trace of albumin The sediment was negative The blood showed a red cell count of 3,900,000, with a hemoglobin of 50 per cent The white cell count was 11,300, 89 per cent polymorphonuclears There was considerable achromia, anisocytosis, and an occasional stippled red blood cell The nonprotein nitrogen of the blood was 35 milligrams and the chlorides were 104 The serum protein was 5.2 milligrams per cent

A portable flat film of the abdomen showed a moderate amount of gas in the bowel overlying the true pelvis and in the region of the cecum and descending colon The cecum did not appear grossly dilated An indefinite rounded area of density was seen superimposed above the region of the ascending colon, just above the crest of the right ilium The diaphragm was low in position Two days later another flat film showed the gas filled colon to be normal in size The rounded areas of density, previously described over the crest of the right ilium, appeared to be within the bowel and had the appearance of a fecolith

On the second hospital day the patient received a transfusion and two days later a laparotomy was performed

DIFFERENTIAL DIAGNOSIS

DR OLIVER COPEL The cause for this patient's entry to the hospital is intestinal obstruction The problem lies in determining first the point of obstruction and secondly the cause The first symptoms of obstruction started six months ago Presumably they were intermittent until two months ago, when the frequency of the attacks of pain suggest that a chronic obstruction existed Complete obstruction apparently occurred a short time before entry and was the immediate cause of her entering the hospital Taking the history alone, the probability would be that the obstruction lies either high in the large intestine or low in the ileum If the obstruction were either in the rectum or sigmoid, in other words low in the bowel, there would have been some change

in the bowel habits. The intermittent attacks of pain would have been accompanied by intermittent constipation. The lack of change of bowel habit is consistent however with obstruction on the right side of the colon or in the terminal ileum. The complete absence of change in bowel habit is strongly suggestive of ileal obstruction. The slight increase in softness of the bowel movement is consistent again with right colon or ileal obstruction. The fact that there was no frank diarrhea again suggests that the obstruction is in the ileum and that relatively normal bowel contents existed in the right side of the colon. Again from the history, the obstruction is probably not high in the small intestine. Vomiting would have appeared much earlier and the patient would not have been able to eat so well as she has. In fact the lack of change in appetite suggests that the obstruction, if in the small intestine must be low in the ileum. It is consistent with such an ileal obstruction as well as with late bowel obstruction.

I am unable to tie up the 'delicate stomach' relieved by sinus operations with the diagnosis. The "delicate stomach" would fit well with an antecedent gallbladder disease but it was apparently relieved seven years ago. I can think of no disease which would give sinus disease relieved for seven years and then give intestinal obstruction. Were there not the long interval of relief, diffuse diseases such as lymphoma, which may present a terminal intestinal obstruction, should otherwise be considered in the differential diagnosis. I am forced to omit the sinus trouble in the discussion.

The physical examination suggests two things of importance. In the first place a small movable firm mass in the right lower quadrant and in the second place a large boggy, balloon like mass. This latter lying in the right lower quadrant presumably would be a dilated cecum, but the small mass if it were the cause of the obstruction should lie above it near the hepatic flexure. The fact that the small mass, which I presume is the cause of the obstruction is differently placed suggests that it lies in the terminal ileum and that the boggy mass must be dilated small intestine.

The laboratory examination is significant. The blood examination is consistent with the recent loss of blood. From the history it is obvious that this loss of blood must have been from the bowel. The fact that the nonprotein nitrogen and the blood chlorides are well within normal limits suggests again that the obstruction if in the ileum must be low. If the obstruction were higher in the small intestine there would have been greater loss of water and salt with an elevation of the nonprotein nitrogen and a drop in the blood chloride. The low serum

protein of 52 milligrams is consistent with hemorrhage. The x ray helps and at the same time it is quite confusing. The second flat plate definitely excludes the large bowel as the origin of the obstruction. A normal sized gas filled cecum places the obstruction in the small intestine. In the first plate a rounded area of density just above the right ileum approximately where the small mass is described in the right lower quadrant, suggests that that mass is a large gall stone. A large gall stone in the terminal ileum is occasionally a cause of acute intestinal obstruction. In the cases that I have seen however no such long history of intestinal obstruction occurred. Once the gall stone had found its way into the small bowel there followed an acute episode of obstruction. I have also never seen bleeding as a complication of gall stone ileal obstruction. Presumably it might occur but the amount of bleeding which this patient had obviously had suggests an ulcerating area of longer duration than would have been produced by a gall stone. The second plate suggests that this mass is in the large bowel and not in the dilated bowel and therefore that it is below the point of obstruction. For these three reasons I dismiss a gall stone as the cause of the obstruction.

Hemorrhage from the small bowel with subsequent acute obstruction can be due to a Meckel's diverticulum but the story of obstruction is of too long a duration. The patient is also of cancer age. If a Meckel's diverticulum is involved in this patient's disease I would go so far as to hazard the guess that it was a carcinoma of the diverticulum with hemorrhage and obstruction. Carcinoma is the most likely disease if one excludes lymphomas. I have never known a lymphoma to give ulceration and bleeding similar to that in this patient.

Carcinomas of the small intestine are very rare. Carcinomas of the large intestine are much more frequent. Carcinomas of the appendix itself which might produce obstruction to the terminal ileum are also rare. Neither a study of the patient nor the x ray examination enables us to make a flatfooted localization of the process. Therefore on the basis of probability, I believe this patient had a carcinoma of the ileocecal valve arising really from the large intestine but causing obstruction of the small bowel alone.

PREOPERATIVE DIAGNOSIS

Carcinoma of the right colon

DR. OLIVER COPELAND DIAGNOSIS

Carcinoma of the ileocecal valve

PATHOLOGIC DIAGNOSIS

Adenocarcinoma of the cecum grade II

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY This patient was explored by Dr. Daland, who found very nearly what Dr. Cope had predicted. The main position of the tumor was in the tip of the cecum, which was markedly contracted. The tumor had grown into the base of the appendix for a distance of about 2.5 centimeters. It had extended on the other side just to the margin of the ileocecal valve although anatomically this did not appear to be markedly narrowed. No

evidences of metastases other than two small lymph nodes in the mesentery could be discovered, so a resection of the cecum, ascending colon and terminal ileum was done. The stump of the ileum was anastomosed to the transverse colon. Microscopic examination showed a well differentiated adenocarcinoma and also proved that the palpable lymph nodes were free from metastasis and enlarged only by an inflammatory reaction. Following operation the patient did well and was discharged relieved three weeks after operation.

THE INCREASE IN INCIDENCE OF DIABETES MELLITUS

It is true that diabetes has been increasing and it is also true that the highest incidence of diabetes is in the United States. However there are several factors which are often overlooked when startling statistics of this nature are published. Thus, in a recent compilation upon the Diabetes Record of 1934 we read that the death rate increased from 18.3 per 100,000 in 113 American cities in 1925 to 25.4 per 100,000 in 169 cities in 1934. As a matter of fact the death rate from diabetes in the Original Registration States increased from 20.4 in 1920 to 28.8 in 1934 or 41 per cent. The corresponding figures for the Registration States of 1920 are 16.1 and 24.1 or 50 per cent. Now it happens that elsewhere in the world where the rates have been much lower the percentage increases have been much more rapid. Thus, in England and Wales in 1920 the rate was 10 and in 1934 16.0 per 100,000 and the increase therefore was 60 per cent. In Scotland in 1924 it was 10

per 100,000 but in 1934 15 per 100,000 or an increase of 50 per cent. In Italy in 1920 the rate was 4.5 but in 1934 it was 9.5 per 100,000 or an increase of 111 per cent. In Montreal in 1920 the rate was 12 and in 1934 18.7 or an increase of 56 per cent. Consequently although the incidence of diabetes is increasing rapidly both in the United States as a whole and in its cities the statistical increases are outdistanced in some other countries and cities and are gradually approaching the United States level.

In estimating the statistical evidence of diabetes in various parts of the world one must always bear in mind the accuracy with which the data are collected. Thus in Canada, statistics show in 1934 the rate to be 12.2 per 100,000 for the whole country whereas for Montreal 18.7 and for Toronto 16.6. Naturally the question arises as to whether in the rural areas in Canada diabetes is as assiduously sought for and diagnosed as in the urban areas and the same thought arises regarding rates in the rural and urban areas of the United States and in different sections of the country.

Other factors likewise must be borne in mind. Diabetes is a disease of middle age and adult life. The older the population the more diabetes can be expected and it is not strange that in New England the diabetes death rate per 100,000 for 1930 was 24.4 the Middle Atlantic States 25.5, East and West North Central States 21.4 and 20.6 respectively and Mountain States 13.3 per 100,000. Whereas the population of Vermont is small and therefore not quite suitable for comparison the rate varied between 29.4 per 100,000 in 1933 and 38.5 per 100,000 in 1934. In Russia according to a recent announcement in the daily press, 46 per cent of the population had been born since 1917 and therefore were nineteen years of age or less. In Massachusetts only 35 per cent of the population in 1930 was under twenty years of age.

The Vermont figures also bring up another fact of importance in evaluating the significance of incidence. Thus there were only 106 deaths in 1933 and 139 deaths in 1934 producing changes in rates from 29.4 to 38.5 per 100,000 respectively. Obviously when dealing with such small numbers there is opportunity for misinterpretation of the facts. Even in a city as large as Boston the deaths changed from 331 in 1934 to less than 300 in 1935. The rate for 1934 was 42.3 per 100,000.

Other factors are of consequence, racial urban versus rural types of population, environmental conditions particularly those leading to obesity due either to ease in securing food or reduction in necessity for muscular work. These conditions cannot be entered into here. They have been considered in detail elsewhere.²

The incidence of diabetes is rising but in general it is increasing now more rapidly in

some other countries than in the United States. The age of the population is a great factor. Two-thirds of all cases of diabetes originate after the age of forty. Consequently, the per cent of the population above forty is important. Thus, in the United States in 1900 23.4 per cent of the population was above the age of forty, whereas 29.4 per cent in 1930. In 1845 in Boston, 80 per cent of the population died under forty years of age, but in Massachusetts in 1935, 80 per cent of the population died above the age of forty years. The increase of diabetes in the United States due to ageing of the population can be expected to go on until the average age of all deaths advances from its present level of 48.7 years to nearly fifty-five years, because this represents about the maximum age incidence for the onset of diabetes. It is true that in the United States the average age at death has advanced nearly one year for each two years (actually from 26.9 to 48.7 years) between 1880 and 1930 but it is logical to infer that increases of longevity and of diabetes in the future will proceed at a much slower pace. However, if one accepts the figures from Thompson and Whelpton's³ book on "Population Trends in the United States" it is evident that the basis for further advances in the number of diabetics will continue for another generation. Thus, in 1900 17.8 per cent of the population was forty-five years of age and over and 4.1 per cent sixty-five years and over. In 1930 these figures were respectively 22.9 and 5.4 per cent, but it is calculated that by 1960 they will rise to 32.6 for forty-five years and above and 9.8 for sixty-five years and over.

THE EFFECT OF RADIATION ON MALIGNANT TUMORS

A CONTROVERSY as long standing as the application of radiotherapy to malignant disease is still unsettled as to the relative importance of the effect of radiation on tumor cells and on the stroma of the tumor and the supporting structures. Most experimental work has centered about the effect of radiation directly on the tumor cell. The work of the French school established the principle that actively proliferating tissues are peculiarly radiosensitive. With this so-called "law of Beigonié and Tribondeau" as a starting point, much attention has been paid to the effects on mitosis, with rather contradictory results owing to the variety of cells and the variety of types of radiation used. In general, the prophase of mitosis is considered the most easily injured.

The one finding on which all experimenters agree is that in any type of tissue, no matter how homogeneous it may appear, whether in the body or growing in tissue culture, the cells fail to respond identically to the radiation. A portion of this different response may be explained by variation in age of the cell, but it must also be influenced by inherent physiological differences in the various cells, irrespective of their age.

We are accustomed to speak of certain tumors as radiosensitive, in view of their marked regression after irradiation. On the other hand, after a satisfactory initial response, the same tumors, once they have recurred, fail to respond anywhere near so favorably, or indeed may not respond at all to the same dosage which gave good results the first time. In spite of the fact that the tumor has changed from radiosensitive to radioresistant, there is no demonstrable difference in the appearance of the tumor cell.

In this regard it is interesting to note that Strangeways and Hopwood found that even in irradiation of cells in tissue culture 100 erythema doses failed to kill every cell in the culture. This amount of x-ray dosage is, of course, far more than any human being could stand. A similar amount of radiation from radium was required to kill all the cells in tissue culture, as is demonstrated in the experiment of Speare.

A most interesting point is that there is a threshold of intensity below which no effect is obtained, no matter how long the radiation may be applied. In other words, even though a dosage of 500 mg. hrs. of radium be given, if the source be of very low intensity practically no effect would be obtained, whereas with a source of greater intensity a marked effect would be obtained.

Study of the histology of x-ray burns led Wolbach and Porter over twenty years ago to emphasize the importance of the effect of irradiation on the supporting tissues. This has been recognized clinically for a considerable period, one of the most striking examples being in the varying response of tumors of the same type according to the position in which they occur. Thus, basal cell cancers of the skin which normally respond well to irradiation when overlying connective tissue or muscle, respond poorly when overlying fat and even more poorly when invading cartilage or bone.

Histologic study of irradiated tumors showed two definite types of effect: an immediate effect on the tumor cell itself, in part exerted on cells in mitosis at the time of irradiation and in part, though to a lesser degree, on the other cells of the tumor. Subsequent to this immediate effect, a delayed effect on the vessels and on the subcutaneous tissue and the connective tissue of the stroma becomes increasingly important.

Thus we may well regard the radiation effect on a given tumor as the summation of the effect on tumor cells in mitosis, on resting tumor cells, on the vascular supply and on the connective tissue of the stroma and the surrounding tissues. That a dosage of x ray or radium will destroy a tumor in the body when it would be insufficient to destroy the cells of that tumor growing in tissue culture shows that there is more than a simple destructive effect on the tumor cells themselves. There must be a secondary effect on the surrounding tissues which leads to the formation of a definitely unfavorable environment for the further development of the tumor cells.

"DEBUNKING" THE SURE CURES

PROFESSOR E V McCollum of Johns Hopkins University in addressing the Kings County Medical Society of Brooklyn, according to our learned contemporary, the *New York Times*, urged the medical profession to forestall the extravagant claims of retailers for the qualities of their medicinal preparations by thoroughly investigating all important new scientific discoveries.

Dr McCollum has added greatly to our knowledge of the vitamins, and is consequently anxious that information which is practically applied should be approximately correct. While conceding that the secretory powers of mucous glands decrease for lack of vitamin A and that the secretions of those glands contain an anti-bacterial substance he sought to dispel the widespread belief that substances rich in vitamin A can prevent infectious diseases. Little if any improvement has been found in the incidence of common colds despite the regular ingestion of cod liver oil, although colds in the cod liver oil groups seem to be milder than in those not so indulging themselves. Vitamin A, however, he considers to be very important to the newly born, and its ingestion should be started early to prevent the cracking of teeth enamel and permanent injury to the tooth structure.

Vitamin B-1 is considered by Dr McCollum to be highly important to the infant, and since milk is relatively poor in this substance, it should be added early to the infant dietary in the form of yeast extracts or other concentrates. Vitamin B-1 has also been found of value to chronic alcoholics, presumably on account of its anti-neuritic properties.

No fairer field for commercial exploitation has been found than that afforded the vitamins, but the success or failure of this exploitation, as Dr McCollum indicates, is largely in the hands of the medical profession.

THE CANVASS OF CHRONIC AND DISABLING ILLNESS

In a letter* to the Secretary of the Massachusetts Medical Society Dr L R Thompson, Acting Surgeon General of the United States Public Health Service makes public the plan for securing the co-operation of physicians in the accumulation of accurate data relating to the incidence of chronic and disabling illness.

This means that as cases of illness of these types are found by the investigators, the attending physicians will fill out and sign blank forms, setting forth the diagnosis in each case which the doctor has attended. For this service a fee of twenty five cents will be paid.

This movement is commendable and should receive the effective support of the medical profession even though the service entailed may not be adequately remunerated.

If this plan is efficiently carried out, a great deal of valuable information will be at the disposal of the Public Health Service and should be the basis for constructive measures in dealing with the problems involved.

We hope that the medical profession will co-operate in this movement.

BRIGHT'S DISEASE IN PREGNANCY

During pregnancy certain kidney complica-
tions often occur. The presence of kidney dis-
ease before pregnancy may make it either im-
possible for the patient to give birth to chil-
dren or inadvisable to make the attempt. Fur-
thermore, the occurrence of kidney complica-
tions during pregnancy may and frequently does
cause loss of life either to the mother or to
the unborn child or perhaps to both. It is ex-
tremely important therefore, both for the pa-
tient and for the physician to know something
of what has gone on before pregnancy and a
great deal of what is going on during it. For
the purpose of this discussion we may classify
the complications which involve or may involve
the problem of nephritis as follows: (a) a group
of complications spoken of as toxemia of preg-
nancy, a group that includes mild toxemia,
sometimes designated as pre-eclampsia, and se-
vere toxemia, which is termed eclampsia and
which is always accompanied by convulsions,
(b) a group of complications depending upon
pre-existing Bright's disease or hypertension or
on both, (c) pyelitis.

Toxemia of pregnancy probably has nothing
much to do with any previous kidney disease.
Its cause is really unknown. It is accompanied
by hypertension albuminuria and evidence of
some disturbance of kidney and liver function.
All of these signs and symptoms generally dis-
appear as soon as pregnancy ends. Numerous
attempts have been made to differentiate the
toxemias of pregnancy and chronic nephritis
and to demonstrate the return of function of
the kidneys acutely damaged by severe toxemia
or eclampsia. It has been demonstrated that
ordinary procedures such as blood chemical
studies, the phenolsulphonephthalein test and
urine concentration test do not help differenti-
ate chronic nephritis and acute toxemias. Re-
cently the urea clearance test has been used for
such a differential study. It was found that the
results of this test checked up well with the
clinical diagnosis, with only a few exceptions,
and that the test gave normal readings in mild
toxemias, decreased readings in severe toxemia
or eclampsia and that the readings were defi-
nitely low with a high degree of consistency in
chronic nephritis. Whether one can reclassify
cases which ordinarily fall in the toxemia group

*This is the last of the series of short selected articles by
members of the Section until Fall
Comments and questions by subscribers are solicited and
be discussed by members of the Section

as a result of urea clearance studies, can only be determined by following such cases over a long period of time

The problem of pre-existing Bright's disease is naturally one of careful diagnosis. Severe Bright's disease hardly need be discussed for the patient is so ill that pregnancy generally is not to be considered and the chances of obtaining a live baby are so remote as to make the attempt questionable. On the other hand mild Bright's disease may exist without the patient's knowledge and definite signs and symptoms may not occur until the kidney begins to demonstrate the strain of advancing pregnancy. Obviously, in mild cases diagnosis of the condition before pregnancy is contemplated is the important point. The above statements apply to any case of pregnancy but perhaps more particularly to those cases that have suffered some form of toxemia in the course of previous pregnancies. In other words physicians are constantly confronted with the question of whether it is safe to allow a patient with a previous history of toxemia to become pregnant again.

The diagnosis of nephritis is not easy. In addition to a careful history and physical examination and careful examinations of repeated single urine specimens such function tests as the fifteen minute phenolphthalein and the urea concentration tests are frequently necessary. This is especially true in those cases where there is any question of a previous nephritis or where there is a history of previous toxemia or repeated attacks of pyelitis. It is possible that the urea clearance test should be included in this diagnostic study but the test is too difficult to be practical and furthermore the results are not so clear-cut as claimed originally.

The difficulty with the problem is that all of the known diagnostic procedures may be used and all may give absolutely normal results and yet the problem may remain unsettled. The point is that there is no test which will indicate the type of response which the kidney will make to some future strain. Not only is this true but the nature of the problem itself is such as to increase the difficulties for all concerned. For example we know that so-called essential hypertension exists in various grades from mild to severe and that the grade depends upon the degree of vascular damage. We also know that in the mild grade frequently no evidence of kidney involvement can be determined and yet this mild grade may at any time shift into a more severe type. A condition like toxemia of pregnancy constitutes a vascular insult from which the patient may entirely recover. We do not know the cause of the toxemia but when we consider the problem of a second pregnancy we must remember that two of the factors which

had something to do with the first attack are still present, namely the type of the individual and the pregnancy. And in addition there is the question of residual damage to the kidney undetermined by any test now available.

The problem of the existence of a mild degree of Bright's disease in its relation to the question of pregnancy still remains unsettled. This is due to the fact that our methods of examination are not sufficiently delicate and that we have no method of determining the nature of kidney response to some future strain. Given a history of previous toxemia or repeated attacks of pyelitis or previous hypertension, careful diagnostic studies should be made before pregnancy is contemplated but, even after all this has been done it is frequently necessary to settle the problem on the basis of clinical judgment with the full realization that one can never be certain what may or may not happen.

ADDITIONAL EXHIBITS AT THE ANNUAL MEETING

The Committee of Arrangements is pleased to announce that since the last issue of the *Journal*, it has secured two additional Scientific Exhibits that were shown at the recent American Medical Association Meeting in Kansas City.

These two exhibits will be placed on the Lower Floor of the Auditorium, just outside the Lower Section Room. They consist of the following:

Booths A, B, C and D—

Diabetes, with Special Reference to the Use of Protamine Insulin

- 1 Diabetic Coma
- 2 Protamine Insulin
- 3 Diabetic Surgery
- 4 Diabetic Statistics

From the George F. Baker Clinic, New England Deaconess Hospital, Boston and the Metropolitan Life Insurance Co., New York City

Booths E and F—

Röntgenologic Study of the Heart. A Series of Mechanical Models

From the Robert Dawson Evans Department for Chemical Research and Preventive Medicine, Massachusetts Memorial Hospitals

By George Levene and Henry H. Lerner, Boston

Booths G, H and I—

Moving Pictures

The Technique of Röntgenologic Study of the Heart

From the Robert Dawson Evans Department for Clinical Research and Preventive Medicine, Massachusetts Memorial Hospitals

By George Levene and Henry H Lerner, Boston

CHANGE IN THE LADIES' PROGRAM

As a result of the flood, it is not possible for the ladies to have their tea at the Old New England Village as was originally planned. In place of this the Committee has arranged for a tea on Monday, June 8, at the George Walter Vincent Smith Art Gallery, 222 State Street, Springfield. Bus leaves Hotel Kimball at 2 45 P.M.

HOW TO REACH THE SPRINGFIELD COUNTRY CLUB

A bus will leave Hotel Kimball, Monday, June 8, at 3 45 P.M. Members driving their own cars, cross the Connecticut River on the Memorial Bridge, turn right on leaving bridge, toward Holyoke. The club is about a mile from the bridge on the left side of the street.

MISCELLANY

THE CONTRIBUTION OF THE MEDICAL PROFESSION TO SPRINGFIELD'S TERCENTENARY CELEBRATION

The general committee of physicians consists of a representative from the staff of every hospital in Springfield and a representative from every medical club or society. Following several meetings during which the final plans were formulated, a subcommittee was organized. This committee has been busy in developing the first event of the Medical Profession's observance. It consists of Dr Arthur J Horgan, Dr Mary Burke, Dr Charles Jurist, Dr James A Seaman and Dr George L Schadt, Chairman.

The Medical Profession's observance of the Tercentenary consisted of three parts. The first event was on Monday evening, May 18. On that day the committee entertained Dr Henry E Sigerist, Director of the Institute of the History of Medicine of The Johns Hopkins University, who delivered the main address at the evening meeting. During the afternoon a number of the local doctors with Dr Sigerist made a pilgrimage to the grave of Dr John Leonard, the first doctor who practiced in Springfield. Dr Leonard probably arrived some time during the first third of the 18th century, or about 1736. Though little is known with reference to him, whence he came or from what school he received his degree, we know he died here on November 28, 1744, in his 69th year and lies buried in the Old Agawam cemetery which is in the town of Agawam directly across the river from Springfield. The doctors placed on the grave of John Leonard a wreath as a token of the local profession's respect and remembrance.

At 6 30 that evening, Dr Sigerist was tendered a complimentary dinner at the Hotel Stonehaven by the physicians of the city.

At 8 30, an open meeting was held in the new auditorium of the Springfield Technical High School. As mentioned above, Dr Sigerist delivered the main address of the evening entitled "The Development of Medicine and Its Trends in the United States, 1636-1936."

This period, as you will note, covers the years of our city.

The second phase of the Medical Profession's Observance of the Tercentenary is the development of a medical exhibit sponsored by the Hampden District Medical Society during the meeting of the State Society at the Springfield Auditorium on June 8, 9, and 10. The committee in charge of this exhibit consists of Dr Gary deN Hough, Dr James M Smead, Dr Fred H Allen of Holyoke, Dr Archibald J Douglas of Westfield, and Dr George L Schadt as chairman. The committee hopes to present an exceedingly interesting exhibit.

As part of the exhibit there will be shown for the first time a series of six panels done in oil by a well known local artist depicting the development of the doctor in fifty-year periods from 1636 to 1936. The artist is already at work on these panels and they will, undoubtedly, develop much interest among the members of the Society.

The final event in our program will take place in the fall when the series of six panels mentioned above will be presented to the Springfield Academy of Medicine by the families, friends and medical societies as a memorial to a number of physicians whose contributions to the life of their city were of outstanding significance. There will be placed on the walls of the Academy a bronze plaque listing the names of these gentlemen.

PHYSICIANS CERTIFIED AS QUALIFIED PSYCHIATRISTS

In our issue of May 7, on page 956, under the title Certification of Massachusetts Psychiatrists, were listed twenty-six physicians certified by the American Board of Psychiatry and Neurology as qualified to practice this specialty.

In our issue of May 14, the statement was made that Dr Riley H Guthrie was also certified as a qualified psychiatrist.

Other Massachusetts physicians certified are Dr Gerald F House, Dr Frank E Leslie, Dr Henry R Viets, Dr W Franklin Wood, Dr Hiram H Merritt, Jr, Dr Tracy J Putnam, Dr M Ralph Kaufman and Dr Kenneth J Tillotson.

AN ADDRESS BY DR WALTER B CANNON

On April 29, 1936, Dr Walter B Cannon, George Higginson Professor of Physiology at the Harvard Medical School, delivered an address on "Sensitization of Denervated Structures" at the seventy-eighth meeting of the Maryland Biological Society of Baltimore—*Science*.

THE AWARD OF THE LESLIE DANA MEDAL
TO DR. JOHN M. WHEELER

Dr. John M. Wheeler, professor of ophthalmology in the Medical School of Columbia University and director of the Eye Institute at the Columbia Presbyterian Medical Center in New York, was presented with the Leslie Dana Gold Medal for "outstanding achievements in the prevention of blindness and the conservation of vision" at a dinner given in St. Louis, in his honor on the evening of May 9. Dr. Wheeler was selected for the award by the National Society for the Prevention of Blindness in co-operation with the St. Louis Society for the Blind

which affers this highly prized mark of recognition annually.

The inscription on the medal reads: "Skilled Surgeon — Great Teacher — Understanding and Sympathetic Friend."

Dr. Wheeler is a former president of the American Academy of Ophthalmology and Otolaryngology. In addition to his work at the Eye Institute of the Medical Center, he is a consultant at six other large New York hospitals. His most publicized operation was performed in 1931 when he removed a cataract from the left eye of the King of Siam — *Bhumibol*. National Society for the Prevention of Blindness.

CORRESPONDENCE

A SUGGESTED PLAN

May 11, 1936

Editor, *New England Journal of Medicine*

One cannot refrain from saying something when one reads in *The New England Journal of Medicine* of May 7, 1936, page 957, under the heading of "Two Worthy Indigent Physicians" a plea, for anyone interested to aid two elderly women physicians

We physicians are supposed to be educated, worldly and broadminded and expect to be respected. What regard can we expect from the people, if such a situation is called to their attention? Their only answer may be, is it possible that the physicians or the Massachusetts Medical Society has no means to help physicians who may be in need of material assistance due to no fault of theirs?

Every other organization consisting of so-called noncollege graduates with degrees or license has ways and means of helping its needy members but we "The Massachusetts Medical Society" have no such ways and means, and an appeal must be made through the columns of *The New England Journal of Medicine* to those who may be interested in contributing money or food. We should all be interested to help.

The Massachusetts Medical Society should bow its head in shame. We should have a special fund and each Fellow should be requested to contribute a reasonable sum yearly and such funds should be put away and used to help any Fellow who may be unable to support his family or himself.

We can easily raise funds for such a worthy cause and many of those who are more fortunate than others, may contribute additional sums to the Fund.

Our Annual Meeting is scheduled for June 8, 9 and 10 in Springfield. The Fellows should be interested enough to bring in resolutions whereby such a fund could be established for the use of any Fellow who may need aid.

BERNARD ZUCKERMAN, M.D.

ILLNESS*Treasury Department
Public Health Service
Washington

May 12, 1936

Secretary, Massachusetts Medical Society
Dear Dr. Begg

The field staff of the National Health Survey, carefully trained in gathering detailed, accurate information, has completed the extensive canvass of chronic and disabling illness conducted by the

*In a personal letter to Dr. Begg, Secretary of the Massachusetts Medical Society, Dr. Thompson requests that this letter be read at meetings of the District Medical Societies of which physicians of Boston, Fall River, Greenfield, Ipswich and Pittsfield are members because the study was conducted in the several cities named.

United States Public Health Service in nineteen states

When the study was initiated last fall, the program was discussed in the October 5 issue of *The Journal of the American Medical Association*. As announced at that time, there was special realization of the great value that would accrue to this scientific survey if supplementary facts could be obtained from physicians in cases of medically attended illnesses. Accordingly, when medical attendance was reported, permission to secure additional data from the doctor was requested of the family by the field worker. Assured that the information would be regarded as confidential and would be used for purposes of statistical compilation only, families were co-operative in granting this privilege of confirming diagnoses.

Appropriate forms are now being received by the attending physicians named by informants, and the Health Survey is asking the co-operation of members of the medical profession in this very important phase of the study. It will be appreciated if you will announce the confirmation plan to your Society, urging the desirability of having the forms returned as promptly as possible.

For each form filled and returned the physician will receive a fee of twenty five cents, a small compensation for the service he will render in executing the blank. By supplying the information requested he will contribute invaluable data to this study and assure the scientific accuracy of the results.

Very sincerely yours,

L. R. THOMPSON,

Acting Surgeon General

TO THE MEDICAL PROFESSION OF MASSACHUSETTS
FromL. R. Thompson
Assistant Surgeon General

Within a short while, many physicians will receive from the Surgeon General of the United States Public Health Service a request for information relative to the correctness of the diagnoses as reported by certain of their patients. The information solicited is to be returned by mail directly to the Surgeon General. *It will be treated as strictly confidential and will be used for statistical analysis only.* Thus, the ethical and legal standards of the medical profession are in no way violated.

A sum of \$200,000 has been set aside from which to pay twenty five cents (25¢) for the filling out of each medical report by the physician. Physicians will receive report forms to be filled out in groups of ten or more.

During the past five months, the United States Public Health Service has been conducting a National Health Inventory, which has comprised the collection of data from 800,000 families, representing various economic and social levels of the general population.

The survey was designed primarily to obtain use-

ful statistics upon the incidence of the chronic and disabling illnesses as well as upon the various economic, social and material factors in the environment which may predispose to such conditions

The actual collection of factual data from the 800,000 selected families by specially trained lay canvassers has now been brought to a close. Care has been taken to avoid having the lay enumerators collect actual medical information. In every instance the enumerator has simply asked the household during the past twelve months and has recorded only the exact words of the informant. Many of the schedules have of course recorded no illness at all.

For those family schedules upon which an illness is recorded the attending physician is also recorded and the head of the household or his wife or some member of the household in a position to give such permission has been asked to grant the Surgeon General permission to confirm the reported illness or illnesses with the attending physician.

It is now planned to obtain additional information as to the recorded illness from the physician who treated the case. In all of the 95 cities where the survey is being conducted the co-operation of the local medical society has been obtained.

The United States Public Health Service in initiating this survey has used every precaution to make the study scientifically accurate. It has been conducted on the same lines and in accord with the policies laid down by the Service many years ago. The doctor holds a most important position in supporting the scientific value of the material collected. Therefore I am taking the liberty of requesting on behalf of the Service your active co-operation in securing from those physicians concerned in the actual reporting of cases recorded in the survey and from those interested in collection and dissemination of epidemiological statistics.

RECENT DEATHS

CURRAN—SIMON FRANCIS CURRAN M.D., of 104 Norfolk Street Dorchester died at his home May 19 1936

Dr Curran was born in 1874 and graduated from the Tufts College Medical School in 1902. His pre-medical education was acquired at Tufts College where he was prominent in athletic activities. He served as captain and later as major in the World War and had been President of the St. Vincent de Paul Society at St. Matthew's Church in Dorchester.

Dr Curran had been in poor health since he was injured by a fall in 1935 and had recently submitted to a surgical operation at the Boston City Hospital. Two brothers William B. of Waltham and John J. of Dorchester and three sisters Mrs. Katherine Gill of Dorchester Mrs. Elizabeth Brown of Lowell and Miss Gertrude A. Curran of Dorchester survive him.

JENCKES—JOSEPH FRANKLIN JENCKES M.D., of Wrentham Massachusetts died at the home of his son in Providence R. I., May 18 1936. Dr Jenckes was born in 1848 the son of Joseph Smith Jenckes and Harriet Bismore Jenckes of New Bedford.

His medical degree was conferred by the University of Vermont College of Medicine in 1882. He practiced in Wrentham for more than fifty years.

Dr Jenckes was Chairman of the Board of Trustees of the Fiske Public Library from 1882 until his death and had served on the Wrentham School Committee and Board of Health. Dr Jenckes was an Odd Fellow a Mason and a member of the Thurber Medical Association.

HASKINS—FRANK EUGENE HASKINS M.D. of 204 Huntington Avenue Boston died at his home May 24 1936 after a long illness. He was born in 1874.

Before studying medicine Dr Haskins was a graduate of the Massachusetts College of Pharmacy. He later entered the Tufts College Medical School and graduated therefrom in 1903 later becoming Professor of Pharmacology and had also served as Secretary of the Medical and Dental School Faculty.

He was a Fellow of the Massachusetts Medical Society and the American Medical Association and several other medical organizations.

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

The stated meeting of the Harvard Medical Society was held in the amphitheatre of the Peter Bent Brigham Hospital on Tuesday evening, April 14, at 8 15 P M Dr David Cheever presided

Medical and surgical cases were first presented. The first patient, shown by Dr A G Filend, was a twenty-eight year old woman who entered the hospital with the chief complaints of fatigue and moderate diarrhea. In December, 1932, the patient had been operated on for a fistula in ano, and the sinus tract had been shown to be tuberculous on pathological examination. Past history and family history were not otherwise remarkable. The patient entered again in April, 1934, with a story of gradually increasing diarrhea, weakness and fatigue. There was marked pallor, and the hemoglobin had fallen to 25 per cent and the red blood count to 2,000,000. The patient responded well to iron and hydrochloric acid (there was an achylia gastrica) therapy, and at discharge the hemoglobin had risen to 52 per cent and the red count to 3,000,000. Four months before the present admission, the patient ran out of iron and failed to continue to take it. Three months before re-entry, weakness, vague periumbilical pain, and loose bloody stools had their insidious onset. The patient was readmitted with a hemoglobin of 35 per cent and red count of 2,000,000. She has again responded well to increased iron, hydrochloric acid, and protein intakes. The presumptive diagnosis is chlorosis. In discussing the case, Dr C Sidney Burwell mentioned the fact that chlorosis is a vanishing disease and drew attention to the similarity between it and the "primary hypochromic anemia" of adults. There was no evidence of disseminated tuberculosis in this patient.

A fifty year old Negro housewife was presented by Dr Anderson of the Surgical Service. The patient had entered the hospital on April 7 with chief complaints of itching skin and a gradually enlarging abdomen. Family history and past history did not seem relevant. The menopause had come five months before entry. There was no history of indulgence in alcohol. On entry there was a definite icteric tint to the sclerae, and a nonspecific maculo-papulopustular skin eruption. The heart, lungs, and extremities were not remarkable. The abdomen was greatly enlarged and with flatness in the flanks and shifting dullness. No masses were palpable. The blood counts were essentially normal, the icteric index was 40, the nonprotein nitrogen of the blood 24 mg per cent, and the Wassermann reaction was negative. Two days after entry the abdomen was tapped and five liters of fluid removed. Examination of the fluid showed a specific gravity of 1.010 and a cell count of 150 white blood cells per cubic millimeter, with 90 per cent mononuclear forms. No masses were palpable after the paracentesis. The diagnosis was cirrhosis of the liver with ascites. Va-

rious palliative procedures were discussed and exploration was advised.

The chief speaker of the evening was Dr Reginald Fitz who had chosen "Medical Inheritance" for his subject. Dr Fitz presented a very interesting discussion of many ramifications of the subject, graphically illustrated with lantern slides. Of eight hundred men admitted to the Harvard Medical School 20 per cent were sons of doctors. This group of young doctors stood abnormally high in the mental aptitude tests given in medical school, although in actual school grades such a situation did not obtain. Thirty-three per cent of 1725 doctors queried by Dr Fitz showed a familial tendency toward medicine as a profession. Doctors listed in "Who's Who" had a 45 per cent family inheritance. Professors in medical schools showed a similar percentage, whereas the so-called "ordinary graduates" showed a 20 per cent "inheritance." The speaker went on to discuss other aspects of "inheritance" in medicine considered in a general way. Whereas 4500 persons enter the "melting pot" of medicine each year, only 2600 leave by death. Thirty-eight per cent of our doctors fall in the age group of twenty-five to forty-four, 50 per cent forty-five to sixty-four, and 12 per cent over sixty-five years of age. Since 1790, the membership in the Massachusetts Medical Society has increased about proportionally to the increase in population, but the actual increase of doctors in Massachusetts has been much greater. Dr Fitz traced cursorily the profound effects on the practice of medicine and the doctor's social inheritance induced by the development of the telephone, the automobile, electricity, and the influence of the Civil War, the Spanish War, and the World War. He raised the question of whether lay people should have some control over the general regulation of medicine as well as doctors, and personally thinks they should. He traced the development of the State Board of Health and State production of vaccines after the turn of the last century, and mentioned the lessons in efficiency and organization that have been learned from the World War. He showed graphic charts of the influence of the depression on hospital and medical incomes and budgets, and mentioned the great increase in interest of the medical world in socioeconomic problems, as the future and fortunes of medicine become indissolubly linked with the prosperity of the country as a whole. Dr Fitz cannot help but feel that medicine is on the "State Road." Dr Burwell emphasized the modern trends in the way of organization taking place, in discussing the paper, and Dr T B Quigley told briefly of the "middle way" Sweden has taken along the path of socialization.

FAULKNER HOSPITAL CLINICAL MEETING

The last clinical meeting for the current year was held at The Faulkner Hospital on Thursday afternoon, May 7, at 5 00 P M.

Two interesting cases of jaundice which had come to autopsy during the past month were discussed. The first case was one of a fifty-six year old woman, who had had one attack of pain followed by jaundice with subsidence of all symptoms a few months before the present illness. The present illness started with epigastric pain and jaundice. When the jaundice developed the pain subsided. The jaundice persisted. There was no evidence of bile in the stools. It was felt that there was a stone in the common duct which was verified at operation. With out apparent cause clinically or at autopsy following the operation the patient went into collapse and died. The lesson to be learned from this case is the importance of operating on gallstones which are giving symptoms at a time when the patient is not jaundiced or the gallbladder acutely inflamed. Had this patient been operated on in the period between the two attacks when she was not jaundiced the result might have been different.

The other case was one of painless jaundice which had persisted for three and a half months. During the early stages of the jaundice no observation had been made as to the character of the stools. When the patient was admitted to the hospital there was intense jaundice with marked excoriations of the skin due to intense itching. The stools were clay colored. The physical examination except for a palpable liver in the epigastrium was essentially negative. It was felt that exploration was indicated on the chance that there might be a silent stone in the common duct. It was also hoped that the gallbladder could be anastomosed to the intestine if an obstruction was found at the lower end of the common duct, thus relieving the distressing symptom of itching. At exploration a small common duct and a small gallbladder were found showing that there was no obstruction. A probe passed up toward the hepatic ducts easily penetrated into the liver. Just what caused the intense jaundice with absence of bile entering the intestine was not made clear at operation and it was felt that there must be serious damage to the liver in the nature of a hepatitis, although the absence of bile in the intestines would be unusual in such a condition. Following the operation there was considerable hemorrhage which was controlled by placental extract by mouth and thromboplastin inserted into the wound on gauze. Again the actual cause of the patient's death was not established clinically or at autopsy but was felt to be associated with the intense jaundice. At autopsy a carcinoma originating from the bile passages in the neighborhood of the hepatic ducts was found which had become extensive enough to occlude both hepatic ducts. At operation the probe passed up toward the hepatic ducts and had gone through this fibrous tissue with out any obstruction. This location for a primary carcinoma is exceedingly unusual and although this case does not in any way contraindicate exploration as a diagnostic procedure it warns one to be careful about making a promise of relieving itching with

an anastomosis between the gallbladder and the intestines.

Following the presentation of these two cases Dr John S. Hodgson gave a very interesting and instructive talk in regard to some of the points which practitioners should bear in mind when meeting with cases of head injuries which are so common in these days of automobile accidents.

He called attention to the fact that twenty years ago there was too much operating on cerebral accidents and fifteen years ago the pendulum had swung the other way and there was perhaps too much conservatism. The important point is to realize the possible types of injury and appreciate which ones are benefited by operation which by repeated lumbar puncture and which by expectant treatment.

He emphasized the importance of treating the shock which often accompanies these cases and made it clear that there was no hurry in determining by x-ray examination whether the skull was fractured because pressure within the skull rather than the actual break in the bones is the important point in most cases.

In instances where there is suspected bleeding from the middle meningeal arteries it is of interest to know whether the break is in that region and also in certain cases of depressed fractures of the skull, an x-ray is helpful.

He emphasized the importance of palpation of the scalp especially of the bone underlying a break in the skin and warned against confusion between depression in a hematoma of the scalp and depression in the bones of the skull.

He believes in scrupulously cleaning up a scalp wound associated with trauma so that it can be sewed up tight. The history of the case is always important especially in regard to the onset of unconsciousness whether it occurs instantly or develops gradually.

He also emphasized the importance of frequent, careful neurological examinations in order to detect changes in reflexes and muscle weaknesses.

He emphasized the importance of the slow and bounding pulse and of stertorous or irregular or slow respiration. Rising temperature is a bad sign and a steadily rising blood pressure is a bad prognostic sign but in some cases the blood pressure is very little affected. Lumbar puncture in these cases is of considerable diagnostic value and may be of help in treatment. Dr Hodgson does not have the fear expressed by some of the dangers of lumbar puncture if it is carefully done and attention paid to the amount of fluid withdrawn.

If the lesion in the brain is due to a subarachnoid hemorrhage the spinal fluid will show blood and these cases can be cleared up often by lumbar punctures repeated often enough to control the intracranial pressure.

If it is an extradural hemorrhage due to a tear in the middle meningeal arteries a lumbar puncture

will probably not show blood unless the dura is torn also, and these cases must be treated surgically.

The most subtle of the head injuries is the subdural hematoma which is usually over the cortex but may be located at the base. The lumbar puncture in these cases may or may not show blood in the spinal fluid, and if there is blood at the start, it may gradually disappear as these hematomas tend to wall off. The clinical course in these cases is often of valuable aid, for the patients show gradual improvement for a few days and then the condition becomes stationary or the signs and symptoms become more pronounced and positive evidence may or may not be picked up on neurological examination. In these cases, operation is the proper procedure.

He called attention to the cases of concussion and cases of contusion with local or general edema some of which may even have laceration of the brain. These cases usually clear up simply by expectant treatment.

There will be no clinical meetings at The Faulkner Hospital during the summer months, but these meetings will begin again in October.

MASSACHUSETTS GENERAL HOSPITAL CLINICAL MEETING

A clinical meeting of the staff of the Massachusetts General Hospital was held on the evening of March 26, 1936, Dr. Marshall K. Bartlett presiding.

Dr. John Hodgson presented the first paper of the evening on "Lyndau's Disease." This term was first used in 1926 when Lyndau described a group of cases with multiple congenital blood vessel tumors, which are especially apt to involve the retinae and cerebellum. There have been no authentic cases effecting the brain above the tentorium. These congenital abnormalities arise from the mesoderm and are laid down in the third fetal month. The blood vessel abnormalities vary from the capillary to the cavernous type and are most commonly solitary though they may be multiple and occasionally occur in the spinal cord. Pathologically the lesions in the central nervous system are classified as hemangioblastoma and tend to form cysts from the exudation of plasma. The cyst walls are formed of glial tissue. In 20 per cent of the cases reported, more than one member of the family has the condition. The diagnosis is usually made on the discovery of an enlarged artery and vein which proceeds from the central disc to the periphery of the retinae and into a rounded tumor which may be raised several diopters. Dr. Hodgson stressed the necessity of careful ophthalmologic examination, because these lesions may be small and are usually in the periphery. They may later cause glaucoma or separation of the retina. The clinical picture is of a progressive diminution of vision and sometimes pain and cerebellar symptoms. Any of these symptoms may appear first. The eye lesions usually require enucleation, and the cerebellar tumor may at times be completely removed, because they are usual

ly small and near the surface of the brain. When it is impossible to remove them, radiation is of definite benefit. At times there is also a coexistence of this condition with cystic disease of the pancreas and kidneys. The condition is slightly more prevalent in males and a history of injury is frequent. There have been three proved cases at the Massachusetts General Hospital and a fourth probable one.

Dr. Hodgson related the history of these cases, all were males and varied from twenty to forty-five years of age. The cysts were drained in three cases with marked improvement following, but in none could the tumor be entirely excised. In the fourth one, no tumor could be found until postmortem, although a cyst was found in the left cerebellum. Slides were shown of the retinal tumors and of the cerebellum. One of these cases was the first ever to be diagnosed antemortem. Dr. Viets discussed the condition briefly and stressed the importance of wide dilatation of the eyes and a careful ophthalmologic examination.

The second paper was by Dr. W. J. Mixer on the "Operative Treatment of Syringomyelia." A patient was shown with this condition, who, ten years ago had had scoliosis and recently noted weakness and atrophy of the muscles of the right hand and question of some atrophy of the left hand. There was tingling of the extremities, dizziness and headaches. Examination showed a loss of temperature sensation over the right shoulder and some spasticity in both legs. The spinal fluid was negative. The patient was operated on, the cervical cord exposed, found to be enlarged with a cystic cavity within its substance. This cyst was opened in the midline and the inner lining sutured firmly to the arachnoid. The patient is improving rather slowly, but definitely.

These cases frequently have scoliosis and the spinal canal in the cervical region is usually greatly enlarged, as shown by x-ray. The cavity is lined with a smooth membrane which is easily sutured to the arachnoid. Five cases have been treated in the above manner. All had scoliosis and all had cavities in the cervical cord. Three of these have shown improvement and there is hope of greater success in the future when the condition is recognized at an earlier date. Dr. Mixer stressed the fact that all cases of existing scoliosis should have careful examination of the cervical spine, both by x-ray examination and neurological studies.

The third paper was presented by Dr. J. C. White on "Blood Loss in Cranial Operations." Dr. White contrasted neurosurgery and general surgery as to the increased importance of hemostasis in the former type, also a proper fluid balance is more important because of the danger of cerebral edema. He described, briefly, an efficient method of determining the blood loss in any operation. All of the hemoglobin is carefully washed from the drapes and all the blood saved. The amount of hemoglobin is determined, and from it the total blood loss calculated. It was found that in the excision of a meningioma, there is usually a loss of about 2000 cc of blood. In

a bone flap for exploration 500 to 1500 cc. is lost and in a laminectomy 300 cc. This blood loss has been greatly reduced by the use of adrenalin.

Besides the loss of blood at operation there is a great deal of fluid also lost from both sensible and insensible perspiration and from the lungs. In general, a neurological operation results in less sweating than in general operations because there is less sympathetic stimulation. Several cases were studied in detail as to the fluid balance and it was found that in a postoperative patient with a temperature of 101 degrees lost one liter of fluid by insensible perspiration per day. If the temperature was 102 degrees, two liters were lost. A normal person lying in bed loses about 700 cc. in this way. In preventing loss of fluid during operation straight ether is not a good anesthetic because it dilates the brain vessels nor is nitrous oxide and oxygen because here the blood pressure is raised. The ideal anesthetic is avertin (about 90 mg. per kilogram of body weight) followed by novocain and adrenalin locally. Luminal is a good preoperative medication. Dr. White has found that the use of adrenalin diminishes the loss of blood by twenty-five per cent. In turning down a bone flap he said that about 300 to 500 cc. is lost in turning down a bone flap under these conditions and for the removal of an avascular tumor there is some 200 to 500 cc. additional loss. In a vascular tumor 1000 to 1500 additional loss of fluid takes place. For the replacement of blood loss he recommended (1) If the blood loss is 500 cc. or less, the patient should be given 2000 cc. of intravenous saline. (2) If the blood loss amounts to 1000 cc. the patient should be transfused postoperatively and receive 2000 cc. of saline intravenously. (3) If the blood loss is 1200 cc. or above there should be a saline intravenous and multiple transfusions going on during the operation. The patient can take what he needs by mouth usually after the first twenty-four hours. A careful calculation of the intake and output is essential. An excessive fluid intake may do a great deal of damage by causing cerebellar edema. If the patient's kidneys are normal, he can excrete the normal nitrogenous materials in 500 cc. of urine but if he can only concentrate his urine to 1010 he needs to excrete 1500 cc. in a day. A house diet contains about 1000 cc. of fluid whereas a soft-solid diet contains 500 cc. and the water of oxidation from the food intake is about 250 cc.

Dr. Reginald Smithwick spoke on "Hypertension." It has been found in the study of essential hypertension that no treatment thus far described materially influences the course of the disease. It occurs in a wide age range, occasionally coming in the second decade of life and occurring with increasing frequency after this. In the early stages the blood pressure is variable and frequently normal. But as the disease progresses, the average level rises to a high figure and never becomes normal. The pathological changes that occur are arteriolar and are most marked in the eyes, brain, heart and kidneys. Death in 60 per cent is due to heart failure in 20

per cent in cerebral accident and in 10 per cent to renal failure. These patients have a high degree of emotional instability and show a blood pressure rise in response to change of temperature. If the hands of one of these patients are dipped in ice water for a few minutes there will be a marked rise in blood pressure. Sympathectomy at times has been shown to offer relief in a carefully selected group of cases. The several operations which are possible to cut the sympathetic fibers in their course were shown diagrammatically. Following the section of these fibers the blood vessels become sensitized to circulating hormones particularly adrenalin so that the effect of lowering blood pressure is definitely diminished. However this sensitivity occurs to a much less extent if the preganglionic fibers rather than the postganglionic fibers are sectioned although this does not completely abolish this sensitivity. If the adrenals are denervated the effect is greater and the blood vessels react to blood hormones less. The ideal operation accomplishes the sympathectomy of a large blood vessel area by a simple procedure. Some people have sectioned the anterior roots from the sixth thoracic to the second lumbar vertebra but this is a dangerous procedure with a high mortality and results in considerable muscular paralysis.

There are several other possible approaches and Dr. Smithwick pointed out that if the adrenal glands are denervated it is not so important to cut the preganglionic rather than the postganglionic fibers. It has been the feeling at the Massachusetts General Hospital that the most logical operation cuts the three splanchnic nerves. When these are cut the kidneys and adrenals are denervated and these fibers are presumably preganglionic. This operation has had widespread popularity in the past three or four years. At the Massachusetts General Hospital there have been six patients who have had these nerves injected with alcohol and the effects have been slight to striking. Slides were shown on the approach used at the present time at this hospital in which five to six inches of the trunks of the splanchnic nerves are removed. Results from nine cases were reported. Three of the cases were in young people with marked fluctuation of the blood pressure which at times was normal. These patients were then in the early stages of the disease and following operation showed a very definite diminution and a stabilization of the blood pressure with a lowering of the average reading. Three other cases were more advanced with a more striking fluctuation and a blood pressure that was always above normal. In this group there was a material reduction of the blood pressure. In the third group also consisting of three cases the blood pressure was higher the patients were older and following operation there was no change. Dr. Smithwick summed up his talk by concluding that this was a definitely beneficial procedure in the group of cases in which the disease was in its early stages but was of practically no benefit in the more advanced ones.

Dr Palmer spoke briefly on the medical aspect of the disease and pointed out with the exception of age and weight, that in the younger group of individuals the disease is apt to be very intense and rapidly progressive. It occurs more frequently in females and especially if abnormalities of the catamenia are present.

BOSTON SOCIETY OF BIOLOGISTS

A meeting of the Boston Society of Biologists was held on the fifteenth of April in the Harvard Biological Laboratories in Cambridge.

Dorothy R Gilligan spoke on "The Distribution of Solutes Between Plasma and Body Fluids." Edema fluid, pleural fluid, ascitic fluid, lymph, joint fluid and spinal fluid were studied. The chloride ion is always higher in these liquids than in serum and varies with the protein content of the fluid. Careful calculations were made according to the Donnan theory of equilibrium and then compared with the actual ratios figured on experimental data. Except in the cases of calcium and potassium, these experimental and calculated ratios closely resemble each other. It is known that some of the calcium is bound and probably some of the potassium is also bound, thus accounting for the discrepancy in regard to these two ions. Lymph has almost the same composition as serum fluid except that the potassium content of the former is higher. Amniotic fluid approaches the content of serum in early pregnancy, but becomes hypotonic in the later months possibly due to the dilution with fetal urine. Synovial fluid has a high protein content and contains mucin but otherwise is similar to edema. In studying cerebrospinal fluid, it was found that this fluid does not correspond well with Donnan's Law of equilibrium and it is therefore felt that it is not a pure dialysate. The bicarbonate and phosphate content of spinal fluid is lower than it would be if it were a simple dialysate. Mrs Gilligan concluded that subcutaneous fluid, chest fluid, abdominal fluid, synovial fluid, early amniotic fluid, and lymph are simple dialysates in equilibrium with plasma, but that spinal fluid does not fall in the same category.

Dr Robert E Johnson spoke on "Funk's Fat Metabolism Hormone." In 1932 a water soluble substance was extracted from urine and when injected into rats, it caused an increase in acetone bodies, sugar, and lactate in the blood. It is extracted by Doisy's method of extracting sex hormone from urine. The "hormone" is relatively unstable and is completely destroyed in twenty-four hours. It has been found that dogs excrete approximately three times as much following hypophysectomy as they did before, and for this reason it is believed that the substance is not excreted by the pituitary gland. There is no difference before and after thyroidectomy in the excretion of this substance. In normal human beings one liter of urine contains about one unit of this "hormone" but if the castration is made after the patient has exercised

while fasting, there are about seven units per liter excreted. To date there has been no conclusive proof that this substance is a true hormone.

Dr Morgan Upton spoke on "The Time Factor in the Discrimination of Successive Stimuli with Especial Reference to Sound." The so-called "time error" phenomenon has been known for some time. When a second stimulus of the same intensity as the first is heard, it is judged greater or less than the first, depending on the time elapsing between the two stimuli. Doctor Upton has studied this phenomenon and feels that the difference which occurs in the early small intervals of time is representative of some rapidly decaying cortical process and in the longer intervals it is a function of memory. He discussed the various theories that have been promulgated to explain the above effect. Experimentally it is found that if the interval is less than 15 seconds, the second stimulus seems greater than the first. The work of other investigators indicates that there is a range between 15 seconds and 3 seconds where the second stimulus appears to be smaller than the first, while beyond three seconds the second again appears to be greater.

WORCESTER DISTRICT MEDICAL SOCIETY

At the Annual Meeting of the Worcester District Medical Society on May 13, 1936, the following officers were elected:

President, Roy J Ward, Worcester, Vice President, William A Bryan, Worcester, Secretary, Erwin C Miller, Worcester, Treasurer, Edward P Disbrow, Worcester, Commissioner of Trials, Walter P Bowers, Clinton, Censors, Supervisor, George A Dix, Worcester, Charles N Church, Millbury, John J Dumphy, Worcester, Joseph P Mulhern, Worcester, Bancroft C Wheeler, Worcester.

Councillors: James C Austin, Spencer, Walter P Bowers, Clinton, Leslie R Bragg, Webster, Philip H Cook, Worcester, William J Delahanty, Worcester, George A Dix, Worcester, Ernest B Emerson, Rutland, George E Emery, Worcester, Michael F Fallon, Worcester, Homer Gage, Worcester, James J Goodwin, Clinton, David Harrower, Worcester, Ernest L Hunt, Worcester, Edwin R Leib, Worcester, William F Lynch, Worcester, Arthur W Marsh, Worcester, Erwin C Miller (Secretary), Worcester, Joseph W O'Connor, Worcester, Walter C Seelye, Worcester, Edward R Trowbridge, Worcester, Roy J Ward (President), Worcester, Frank H Washburn, Holden, Royal P Watkins, Worcester, Samuel B Woodward, Worcester.

Councillor for Nominating Committee: Principal, David Harrower, Worcester, Alternate, Royal P Watkins, Worcester.

ERWIN C MILLER, M.D., Secretary

ESSEX SOUTH DISTRICT MEDICAL SOCIETY

A stated meeting of the Essex South District Medical Society was held at the Salem Country Club, Peabody, Mass., on May 13, 1936.

Following the dinner at 7 P M the Annual Meeting was held. The following officers were elected:

President—C A Bonner Hathorne Vice-President—E D Reynolds Danvers Secretary—R E Stone Beverly Treasurer—Andrew Nichols III Danvers Commissioner of Trains—O C Blair Lynn Censors—A E Parkhurst (Supervisor) Beverly S N Gardner Salem S R Davis Lynn J J Hickey Peabody L B Hull Gloucester Nominating Councilor—Hanford Carvell Gloucester Alternate Nominating—R E Foss Peabody Councilors—C F Deering Danvers R E Foss Peabody J F Jordan Peabody C L Curtis Salem N P Breed Lynn J W Trask Lynn C H Phillips Beverly W G Philpen Salem J F Donaldson Salem O S Pettingill Middleton A E Parkhurst Beverly Hanford Carvell Gloucester B B Mansfield Ipswich J G Corcoran Hamilton Executive Committee—J R Shangnessy Salem R P Hallett, Gloucester C F Twomey Lynn Sherman Golden, Beverly O S Pettingill Middleton E C Yerbury Hathorne C A Bonner and R E Stone are also Councilors by reason of their office.

Dr Paul Dudley White of Boston then gave a very interesting description of his travels to the ancient shrines of medicine in Greece and Italy. Beautiful moving pictures and lantern slides enhanced the charm of his presentation.

NATHANIEL P BRELD M.D.

THE HARVEY CUSHING SOCIETY

The fifth annual meeting of the Harvey Cushing Society was held in the Mayo Clinic, Rochester, Minnesota, May 15 and 16 1936. The following officers were elected: Dr Kenneth O McKenzie Toronto, Canada, President; Dr Richard Meagher, New York City, Vice-President; Dr Louise Eisenhardt, New Haven, Secretary and Treasurer; Dr Ernest Sachs, St. Louis, was elected an Honorary Member. Corresponding Members chosen were Dr Herbert Olivecrona, Stockholm; Dr Otfried Foerster, Breslau; and Mr Hugh Cairns, London.

The morning sessions were devoted to a program by the members of the Mayo Clinic with presentations of preoperative and postoperative cases and neurosurgical clinics. Contributions by members of the Society included notes on the conservative treatment of tumors of the third ventricle, by Dr Glen Spurling, Louisville; the management of intra-cranial arteriovenous varices, by Dr R. E Semmes; Memphis trauma of the head, by Dr Nicholas Gotten Philadelphia; osteomyelitis of the skull, by Dr Edgar Fincher; ureterodural anastomoses in hydrocephalus, by Dr Frederic Schroeder, Detroit; certain peculiarities of the trigeminal nerve, by Dr Temple Fay, Philadelphia; pneumocephalus following operation upon the sensory root of the fifth nerve, by Dr W G Crutchfield, Richmond; and experimental cerebral edema, by Dr Colby Plicher, Nashville.

A round table discussion was held on the subject of the surgery of hypertension and peripheral vascular disease. Mr Peter Ascroft of London reported

results of his studies in the Department of Physiology, Yale School of Medicine on the treatment of vasospastic states; an experimental analysis in monkeys.

At the annual dinner on Friday evening Dr John Fulton described the various activities of the Second International Neurological Congress in London. The presidential address, 'The Roentgenologist and the Orchestra Leader' was given by Dr Merrill Sosman.

The next meeting is to be held in Philadelphia.

THE GLOUCESTER CANCER CLINIC

The Gloucester Cancer Clinic Committee reports its spring clinic conference which was held at the Addison Gilbert Hospital on May 20 1936. The officiating consultant was Dr George A Leland, Jr., visiting surgeon at the Massachusetts General and the Palmer Memorial Hospital, Boston.

There were approximately twenty-five doctors in attendance from Beverly, Manchester, Hamilton, Essex, Rookport, Gloucester.

Number of patients examined	13
Number of new patients	8
Diagnoses on new patients were	
Cancer of colon	1
Cancer of cervix	2
Question of cancer of stomach	1
Question of early cancer of breast	1
Postoperative cancer, no evidence of malignancy	1
Sebaceous cyst	1

Dr Leland reviewed the patients examined by him at the clinic in January 1936 in order that the visiting physicians might know the types of treatment these patients had received and observe the present postoperative results.

Luncheon was served at the close of the clinical conference.

Submitted by

GLOUCESTER CANCER CLINIC COMMITTEE,
E E Cleaves, M.D. Chairman
Scott W Mooring, M.D.,
Ira B Hull, M.D.
William W Babson, M.D.,
William R Irving, M.D.
Harry C Burrell, M.D.

OFFICERS OF THE MASSACHUSETTS SOCIETY FOR SOCIAL HYGIENE

At the Annual Meeting of the Massachusetts Society for Social Hygiene held April 30 1936 the following designated officers were elected: Dr E Granville Crahan, president; Mrs Nelda H Solomon, vice-president; Elizabeth Ross, secretary; Mrs William Wadsworth, treasurer. Directors for the ensuing year are Dr Harold L Leland, Dr Oayland W Anderson, Herbert C Parsons, Dr George Gilbert Smith, Dr Wilson G Smittle, and Mrs Eva Whiting White, elected on the executive committee, and Dr Anderson, Dr John J Carroll, Dean Lucy

Jenkins Franklin, Dr Homer Gage, Dr Smith, Dr Harry C Solomon, Mrs George Whiting, Dr Alfred Worcester, the Rev Robert P Barry, Dr William B Keeler, Wilford Cook Saeger, Miss Rosanna D Thorndike, Dr L Jackson Smith and Mrs I Tucker Burr

CAPE COD HEALTH BUREAU ASSOCIATION

The spring meeting of the Cape Cod Health Bureau Association was convened in Hyannis on Friday, May 8, Vice-President Howes in the chair. At the business session the routine reports were followed by a vote to devote \$250 of the reserve fund to the equipping of the proposed local milk and water laboratory in the Court House in Barnstable. This, with milk inspector George F Crocker, Jr, in charge, will furnish to the Cape a home laboratory, and avoid the delay and costs now incident to the testing of samples in Boston or in Amherst.

The election of officers to serve for the coming year resulted in the following: President, Mr I Grafton Howes of Dennis, Vice-President, Mrs Jeanette M White of Sandwich, Secretary-Treasurer, Mr C R Bassett of Yarmouth, and Executive Council, Dr Richard P MacKnight of New Bedford, Dr A P Goff of Hyannis, Mr E T Ward of Yarmouth and Dr J G Kelley of Pocasset.

Dr R P MacKnight, State District Health Officer for southeastern Massachusetts, was the principal speaker, discussing various duties of boards of health and emphasizing the need of accurate and complete records. In his work Dr MacKnight very frequently encounters unfortunate conditions. When a case of diphtheria is reported, for example, it is important for the nurse to know the immunization conditions of possible contacts, and the absence of records makes her work uncertain and difficult. A mere notebook record is really not sufficient, there should be card records, kept up-to-date, and records of those not immunized should be included.

The same is true of tuberculosis, for the nurse looks at once through the family and other contacts. In populations which include many foreigners, and this is characteristic of a good many towns and cities in southeastern Massachusetts, the problem, if records are not available, becomes difficult.

Incidentally, the speaker noted that good records have their effect on the incidence of some diseases, since the authorities can employ preventive measures, and as in Falmouth, which has had no case of diphtheria in three years, be reasonably assured of improved health conditions.

In scarlet fever, attention should be given to the milk supply, with inquiries as to its distribution and care, and health conditions of milkers and the stables, whether clean or dirty. These items should be of record in form available for consultation. The pasteurization of milk is an effective precaution.

Dr MacKnight next discussed venereal diseases, one of the important problems in this section, due in part to the character of its population, and the secrecy incident to the disease. Health departments

might declare individual cases to be dangerous to the community, but the evidence is very difficult to obtain and the law limits the use of this information when it is obtained.

In closing, Dr MacKnight stated it to be his opinion that measles ought to be better controlled. With typhoid fever, examinations have increased the number of known carriers, and these can be controlled.

The round table discussion that customarily follows the papers read at these meetings was devoted largely to various aspects of the venereal disease problems.

Mr J L Glennon, chairman of the New Bedford Board of Health, spoke of the milk control in his city, noting that in 1923, 700 babies died in the first year of life, while in 1935, the figure was only 97. Mr W G Kirschbaum, of the same board, stated that there are only two houses placarded for communicable diseases today in his city, with a population of 110,000. New Bedford has, for twenty-nine months, been without a death from diphtheria. Dr J G Kelley, superintendent of the hospital at Pocasset, said that his institution is conducting a clinic for venereal diseases. Two babies that under former conditions would have had congenital syphilis had been born free from the disease. The clinic is as yet only an experiment.

WILLIAM HARVEY SOCIETY

The April meeting of the William Harvey Society was held on April 10 in the Beth Israel Hospital, Boston.

Dr Elliott C Cutler spoke on "War Surgery." He began his talk by pointing out the better side of war and discussed the mechanism by which capable men are advanced much more rapidly than could occur in civil life, while the less capable ones quickly find their place in a corresponding position on the military scale. Dr Cutler gave a very interesting and highly entertaining account of some of his numerous experiences at or near the front during the World War. He amply illustrated his speech with maps and lantern slides. He took his material from three large volumes of papers that he collected and wrote during the trying years of the war. This often meant spending thirty minutes' writing, out of the five hours that was allowed for sleep. All of the experiences that he recounted from the occasion when the hospital was bombed to the organization of an evacuation hospital, which had to dispose of a thousand wounded daily, were told in Dr Cutler's fascinating manner and contributed to a thoroughly enjoyable evening.

THE FRANKLIN COUNTY PUBLIC HEALTH ASSOCIATION

Miss Elsie F Smith, Executive Secretary of the Franklin County Public Health Association, reported at the annual meeting of the Association held in Greenfield, Massachusetts, April 1936, that during 1920 thirty-five persons died of tuberculosis, whereas in 1934 only ten deaths from this disease were

recorded. The number of cases of tuberculosis has declined from 630 in 1920 to an average of 147 pulmonary cases in the past five-year period and 81 childhood cases.

The Treasurer reported a satisfactory financial condition of the Association. Dr. John B. Hawes, 2d, of Boston gave an inspiring address explaining that there are three fundamental functions which should be actively in operation in the fight against tuberculosis. These are education, demonstration of existing conditions and intelligent research directed against the etiologic factors underlying the incidence of tuberculosis in any community. He especially emphasized the importance of follow-up work in dealing with contact cases as well as those with a demonstrative infection.

The meeting was presided over by Dr. Charles Moline. The officers elected for the ensuing year are the following: President, Dr. Charles Moline; First Vice-President, Mrs. H. R. Sargent; Second Vice-President, Mr. W. Herbert Nichols; Secretary, Mrs. A. L. Johnson; Treasurer, Mr. Herbert V. Erickson. Mr. Marvin E. Jones and Mrs. Raymond L. Dunnell were elected to the Board of Directors for three years. Miss E. F. Smith was reappointed Executive Secretary.

SOCIETY MEETINGS CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JUNE 1, 1936

Tuesday, June 2—

9:30 A.M. Massachusetts General Hospital. Thoracic Clinic.

Wednesday, June 3—

8 A.M. Massachusetts General Hospital. Orthopedic Grand Rounds.

11:20 A.M. Clinico-Pathological Conference. Children's Hospital.

Thursday, June 4—

8 A.M. Massachusetts General Hospital. Circulatory Clinic.

*10:30 A.M. Clinico-Surgical and Orthopedic Staffs of the Children's Hospital at the Children's Hospital.

9:16 A.M. Massachusetts General Hospital. Neurological Conference.

1 P.M. Massachusetts General Hospital. Clinico-Pathological Conference.

Friday, June 5—

10:30 A.M. Massachusetts General Hospital. Fracture Clinic.

Saturday, June 6—

10 A.M. 12 M. Staff Rounds at the Peter Bent Brigham Hospital. Conducted by Dr. Henry A. Christian.

*Open to the medical profession.
*Open to Fellows of the Massachusetts Medical Society.

May 28—New England Obstetrical and Gynecological Society will meet at Providence R. I.

May 28—Clover Hill Hospital Medical Lecture. 161 Berkeley Street at Lawrence at 9 P.M.

May 28—Brocton Medical Society will meet at the Commercial Club, Brocton, at 30 P.M.

May 31—June 1—International Cardiological Meeting Royal (Australasian) Assembly of Physiologists, Pathologists and Therapists. See page 54 issue of April 9.

June 2—Lawrence Cancer Clinic. Lawrence General Hospital, 1 Garden Street at 10 A.M.

June 4, 5 and 6—Annual Meeting of the American Dermatological Association at the N. W. Ocean House, Swampscott.

June 4—July 3—Massachusetts Institute of Technology Department of Biology and Public Health. See page 1012, issue of May 14.

June 8—Tufts Medical Alumni Luncheon. See page 1047 issue of May 1.

June 8, 9 and 10—American Association for the Study of Gout. See page 1075 issue of May 1.

June 9—New England Alumni. See page 1047 issue of May 1.

June 9—Massachusetts Medical Legal Society. See page 1047 issue of May 1.

June 9—Massachusetts Diplomates of the National Board of Medical Examiners. See page 1047 issue of May 1.

June 15—19—The Executive Board of the Catholic Hospital Association will meet at the Fifth Regiment Armory, Baltimore, Md.

June 15—July 25—Summer Course in Bacteriology. See page 255 issue of February 20.

June 22 and 23—The Medical Library Association. See page 1075 issue of May 1.

June 29—July 11—Hospital Administration. See page 1077 issue of May 1.

September 1936—First International Congress of Sanatoria and Private Nursing Homes. See page 303 issue of April 16.

September 7—10—International Union against Tuberculosis. See page 554 issue of March 1.

September 29—October 3—First International Conference on Fever Therapy. See page 1075 issue of December 6.

October 12—15—Third International Congress on Malaria. See page 1075 issue of May 1.

October 19—23—Clinical Congress of the American College of Surgeons. See page 180 issue of January 23.

April 21-24, 1937—American Society for Experimental Pathology. See page 1075 issue of May 1.

BOOK REVIEWS

Consultations de Cardiologie. Georges Marchal. 227 pp. Paris: Masson et Cie. 25 fr.

This small volume of some two hundred pages presents in an interesting way by case histories and discussion the clinical points of view concerning diagnosis and treatment of one group of the French cardiological school, namely that under Charles Laurry. There are thirty chapters, mostly short, of a few pages each, discussing the following subjects:

1. The evolution of mitral stenosis.
2. The rheumatic origin of aortic insufficiency.
3. The evolution of cardiac rheumatism with heart failure and enlarged liver.
4. Rheumatic pericarditis.
5. Disappearance of signs of valvular defect in a case of acute articular rheumatism.
6. Subacute streptococcus endocarditis.
7. Syphilitic aortitis with left ventricular insufficiency.
8. Neurocirculatory asthenia with an erroneous diagnosis of aortitis.
9. Syphilitic myocarditis with latent aortitis.
10. Juvenile aortitis due to congenital syphilis.
11. Aneurysm of the arch of the aorta.
12. Senile heart with stationary sclerotic valvular lesions.
13. Senile heart with left ventricular insufficiency.
14. Appearance of ulcer of the stomach due to cardiac insufficiency.
15. Myocardial infarct.
16. A case of extrasystoles.
17. Nodal paroxysmal tachycardia.
18. Syndrome of Adams Stokes with total bradycardia.

- 19 Syndrome of Adams Stokes, with complete dissociation
- 20 Syndrome of Adams Stokes, with mixed bradycardia
- 21 Syphilitic pulmonary arteritis with right ventricular insufficiency
- 22 Maladie bleue, with polycythemia
- 23 Cardiac neurosis of the menopause
- 24 Aerophagia masked as angina pectoris
- 25 Malignant arterial hypertension with aortic insufficiency
- 26 Complete arrhythmia with cardiac insufficiency in thyrotoxicosis
- 27 Case of "curable" myocardial infarct
- 28 Grippe with cardiopulmonary symptoms
- 29 Severe cardiac insufficiency in a case of filariasis cured by x ray therapy of the spleen
- 30 Cardiac insufficiency in the course of pernicious anemia

There is a preface by Professor Laubry

The "consultations" are entertainingly written, and contain many points of interest and value, for example, (1) the comments about the erroneous diagnosis of aortitis with dilatation of the aorta made on x ray study in a patient who had had syphilis at one time, but at the time of the examination only neurocirculatory asthenia (Case 8), (2) the recognition of the prolonged activity of the rheumatic infection, and (3) the insistence on rations of rest in the treatment of heart weakness

There are a good many points in the discussion of the cases with which most of us on this side of the water would not agree, for example, in Case 1 the likelihood of a presystolic murmur in the presence of auricular fibrillation, aortic regurgitation produced by the displacement of the aortic cusp by a sclerosed mitral valve, the combined use of digitalis and ouabain, the routine use of much salicylate therapy in rheumatic cases, the use of iodine and sulphur in cardiovascular disease, the possibility of valvular disease subsiding with a disappearance of the murmurs instead of the more rational explanation of the causation of the murmurs in dilatation of the heart, and the failure to treat thyrotoxicosis with cardiac involvement by subtotal thyroidectomy. In general one is unfavorably impressed by the polypharmacy

One suggestion of particular interest that comes from several of the chapters is the plan of giving prophylactic antistreptococcus injections in cases of valvular disease to prevent the complication of subacute bacterial endocarditis. On page 47 there is a statement that one case of secondary streptococcus endocarditis did develop despite the use of regular injections of vaccine in a number of cases over a period of four years. However, it is to be remembered that only about one case of twenty five or more of rheumatic valvular disease develops subacute bacterial endocarditis anyway. Nevertheless the subject is an interesting one, and the procedure may possibly be of value

For a survey of many of the views of the French cardiologists this volume can be recommended, but it must be read very critically

The Treatment of Diabetes Mellitus Elliott P. Joslin 620 pp Philadelphia Lea & Febiger \$6.00

In 1814, was published the first edition of Dr Jacob Bigelow's famous "Florula Bostoniensis". With characteristic modesty of the time he remarked of this book, "I flatter myself that among its faults, the most numerous will not be its errors, and whatever may be its fate with the public, I shall retain the consciousness that it has not been the result of superficial inquiry or negligent observation."

Dr Joslin's "Treatment of Diabetes Mellitus" has come to be regarded by all New Englanders as one of the most distinguished of Boston's perennials. Appearing for the first time in 1916, subsequent plantings have budded forth in 1917, 1923, 1928 and 1935, each one breeding true to form and demonstrating to the medical world everything that is worth knowing about *Lathyrus odoratus*.

The 1935 specimen is much like its predecessors. It has been developed primarily, as were the earlier ones, to record for others those facts which have proved of particular service to Dr Joslin in the treatment of diabetes. The knowledge of this disease has grown rapidly. All that Dr Joslin knew of the treatment of diabetes in 1916 could be encompassed in 440 pages, twelve years later, a book of 998 pages was necessary to yield the information which he regarded as essential. The latest volume has been shortened perceptibly without, however, losing anything vital from its contents, and yet, at the same time, it has been broadened to include new knowledge regarding the pathologic physiology of diabetes which has come to light in recent days. As usual, this edition is a fine piece of bookmanship.

Dr Joslin's textbook is a difficult one to characterize. Certainly, to copy Dr Bigelow's postrevolutionary restraint, one can at least say of it without fear of contradiction that among its faults the most numerous are not its errors and that the book has not been the result of superficial inquiry or negligent observation. One can even go farther and agree with the more expansive *Boston Medical and Surgical Journal of the Great War* (176:577 [April 19] 1917), "There is nothing the internist or general practitioner might want to know concerning the treatment of diabetes that is not presented in this admirable book. It is indeed rare that one is privileged to recommend so wholeheartedly such a book to the medical profession." Or perhaps, as a final word, one should act one's age. What the postwar *New England Journal of Medicine* (200:1012 [May 9] 1929) said a few years ago had best be repeated: "Boston must not fail to acclaim the appearance of a new edition of Dr Joslin's famous textbook. Any survey of this most important work is inadequate. A study of the book itself will more than repay any reader."

"SPRAY X RAY THERAPY" IN POLYCYTHEMIA VERA AND IN ERYTHROBLASTIC ANEMIA*

BY FRANCIS T. HUNTER, M.D.†

IRRADIATION of the body as a whole with high voltage röntgen rays—diversely termed "total irradiation," "teleröntgenotherapy," "röntgen baths," or "spray therapy"—was first proposed and used by Teschendorf.¹ Since the publication of his paper in 1927 experience has shown that in cases of generalized leukoerythroblastosis and in instances of widespread radio-resistant tumors, therapy of this type is no more efficacious than discontinuous irradiation through limited fields. Nevertheless in the handling of certain radiosensitive hyperplasias and neoplasms widely distributed throughout the body this form of röntgenotherapy possesses in theory at least, an advantage over the older method of treatment, in that the whole mass of morbid tissue is evenly and simultaneously subjected to the action of the rays. According to a number of observers in recent years have employed it in cases of leukemia and lymphoblastoma but it must be confessed opinion as to its usefulness in these conditions is so far not uniform.

POLYCYTHEMIA VERA

On the other hand the results in the few recorded instances of its use in polycythemia vera seem to have been satisfactory enough to evoke mild enthusiasm. First utilized in this malady by Sgalitzer,^{2,3} "spray therapy," according to him, produced in thirty-four cases, remissions of from one and a half to five and a half years duration. None of his three reports, however, contain protocols of the cases or detailed accounts of the blood examinations. Palmeri⁴ in 1933 reported satisfactory therapeutic results in two cases, but of these, one patient was followed for only ten months, the other for a scant five days—observation periods obviously too brief to allow proper evaluation of the method. Likewise Marchal et al.⁵ have recorded a patient observed over a period of five and a half months, in whom the red blood corpuscles fell from an initial figure of 6,200,000 per cu mm to 620,000 per cu mm after a to

tal dosage of 205 r units. But since no other investigators have made contributions to the subject, and no original observations on the effect of "spray therapy" in polycythemia vera have yet appeared in the English language, it was thought that a more or less complete report on two patients suffering from this disease, who were given "spray therapy" and closely followed for three years, might be of interest.

CASE 1. *Polycythemia Vera—Multiple Thromboses*

The patient, H. A., was a white native housewife aged forty-nine who entered the hospital October 27, 1932, complaining of painful swollen legs.

Present illness. In 1910 during her second pregnancy and again in 1915 while carrying her third child the patient observed transient, nontender varicosities on the medial side of each thigh. With this exception her medical history was uneventful until about ten months prior to entry when a red tender subcutaneous lesion 3 cm. in size made its appearance on the inner aspect of the left leg just above the knee. This was accompanied by swelling of the leg and by a dull aching femoral pain. Some two or three weeks later—in February 1932—she suddenly experienced a severe pain in the right chest, sharp in character and exaggerated by inspiration, which gradually decreased in severity and which at the end of a week's time had disappeared. She was informed, presumably by her medical attendant, that it was a manifestation of pleurisy. In the early part of March, a new subcutaneous nodule similar to the first appeared on the right leg and it too was followed by femoral edema and "pleurisy." From that time until entry to the hospital, several lesions of like nature had been noted on the thighs and abdomen and for the past month both legs had been persistently enlarged.

The family history except for a story of asthma in the mother and of hay fever in one sister was noninformative.

The marital history and the **past history** added no essential facts.

Physical examination showed a well-developed obese woman with plethoric facies. There was definite choking (2 diopters) of each optic disc and obliteration of the physiological cuppling. The retinal vessels were dilated and tortuous and there were many hemorrhages into the retinae—an appearance consistent with thrombosis of both central retinal veins. On each side of the neck, the jugular vein could be palpated like a cord. No variation from the normal could be detected upon examination of the heart and lungs. The blood pressure was 150/90. A red slightly tender indurated, subcutaneous lesion 12 cm. in diameter was present on the right lower abdomen—apparently thrombosis of the subcutaneous veins. The liver and spleen were thought to be enlarged. Each ankle showed slight pitting edema. There was no elevation of temperature.

†From Francis T. Hunter, M.D., Assistant Physician, General Hospital, Boston.
Work 14, page 1125.

Laboratory findings Examination of the urine revealed no abnormalities. A blood Hinton test proved negative. The basal metabolic rate was plus 2 per cent. The sedimentation rate was 3 mm at the end of one hour (normal 20 mm). Blood examination showed red blood corpuscles 8,500,000 per cu mm, hemoglobin (Sahli) 125 per cent, white blood corpuscles 12,000 per cu mm. Except for a polymorphonuclear percentage of 85, the stained specimen exhibited no variation from the normal. The hematocrit reading gave 60 per cent cells, the oxygen capacity was 24.11 volumes per cent.

"Spray therapy" was begun November 11 and was continued through December 7, 1932. The apparatus was operated so as to deliver to the patient about 20 r per hour (measured in air), at a target skin distance of 215 cm, through 0.5 mm of copper and 4.0 mm of celluloid, MA 4, KVP 200. A total of 304 r was given in eleven sittings. A

Present illness For the period between 1920 and 1930 he could recall episodes of headaches accompanied by vomiting of material which at times resembled "coffee-grounds." There was a dim recollection of indigestion, and a more vivid impression that he had passed tarry stools on occasion. About two years prior to entry these symptoms subsided to some extent and were replaced by dyspnea and palpitation on exertion. About the same time his attention was called to a mass in the left upper quadrant of the abdomen. Three or four months before entry, he began to feel weak and experienced in the region of the mass an intermittent aching pain, which occasionally radiated to the epigastrium, and which was usually made worse by lying down. He again observed tarry stools and became convinced that the swelling in the left upper quadrant had grown larger. During the past two months there had been a loss of ten pounds in weight.

FIG 1

second course of treatment (with the same arrangement of the apparatus) was begun on January 24, 1933 and completed on February 28, 1933. In this course of therapy 598 r were administered in twenty-six sittings. Thus a total of 904 r was received by the patient in about ten weeks' time.

Course This is best seen by reference to figure 1, on which is depicted the erythrocyte and leucocyte counts during the treatment and for the follow-up period of three years. The general improvement of the patient closely paralleled the lowering of the erythrocyte count, and at the last visit she appeared to be normal in every way.

CASE 2 Polycythemia Vera—Duodenal Ulcer—Pulmonary Tuberculosis (inactive)

A. G., a fifty-two year old, white, married grocer,—born in this country of Italian parents,—entered the hospital August 3, 1932 complaining of not feeling well and of an aching in the upper left abdomen.

The family history and the marital history were nonessential.

Past History Aside from diseases of childhood, he had never undergone a serious illness. For thirty-three years he had experienced, from time to time, migratory arthritic symptoms, consisting of red, nontender swelling about various joints. On three occasions during the past decade, ecchymoses had appeared without adequate cause,—once on the terminal portion of the thumb and twice about the orbit.

Physical examination showed a poorly developed and nourished man with pallor of the mucous membranes. Arteriosclerosis of the peripheral vessels was marked. Examination of the heart and lungs revealed no obvious abnormalities. The blood pressure was 140/80. A slightly tender irregular tumor was visible and palpable in the left side of the abdomen, and this mass, which was thought to be an enlarged spleen, extended to the level of the

umbilicus. The temperature fluctuated between 98 and 100 F.

Laboratory Findings Urinalysis and the blood Hinton test were negative. Stool examination revealed no traces of occult blood. An intradermal tuberculin test in 1/1000 dilution was negative. Blood examination showed red blood corpuscles 5,300,000 per cu. mm., hemoglobin (Sahli) 45 per cent. In the blood smear the polymorphonuclears made up 91 per cent of the leucocytes and the erythrocytes exhibited marked achromia.

X-ray studies confirmed the presence of a mass extrinsic to the stomach, in the left upper quadrant of the abdomen. There was a constant deformity of the duodenal cap consistent with ulcer. The lungs showed infiltration and cavitation at the left apex, and plates of the spine revealed marked arthritic changes.

Reentry to the hospital March 8 1933. The patient now complained of heaviness of the head, pounding in the ears, and moderately severe frontal headaches recurring about every ten days. There had been no gastrointestinal symptoms. **Physical examination** except for a dark red cyanotic color gave the signs previously described. **Laboratory findings** Blood examination showed red blood corpuscles 10,630,000 per cu. mm., hemoglobin (Sahli) 125 per cent, polymorphonuclears 85 per cent, red blood corpuscles normal in appearance. The stools showed no occult blood, the basal metabolic rate was plus 41 per cent, and the hemocrit reading gave 65 per cent cells. Re-examination of the chest and gastrointestinal tract by the x-ray revealed no change.

The patient was discharged March 24 1933 with the diagnosis of polycythemia vera.

FIG. 2

The patient was discharged August 21 1932 with a questionable diagnosis of lymphoblastoma.

Progress High voltage röntgen therapy to the abdominal mass through a 20 cm. x 20 cm. anterior field, at a target skin distance of 50 cm. was begun in the Ray Treatment Clinic on August 23. A total of 600 r. was administered in divided doses between September 21 and September 26. 800 r. additional were given to the posterior abdomen through a field of the same size.

December 1932 The patient felt much better and had gained seventeen pounds in weight. He now however showed injected sclerae, a high color and a suggestion of cyanosis. The red blood corpuscles numbered 6,700,000 per cu. mm.

February 1933 The patient's color was a deeper red than at the last observation. The red blood corpuscles were 11,375,000 per cu. mm. the hemoglobin (Sahli) 160 per cent. It was thought that the unusual blood picture seen the previous August must have been caused by bleeding from the duodenal ulcer.

"Spray therapy" was given between June 6 and July 20 1933 but it was subsequently discovered that because of difficulties encountered in computing dosage, the patient had received during this period only a fraction of the prescribed amount of therapy [Note that the erythrocyte count did not fall during this time]. A new course of therapy was begun on September 25 and completed on October 20 1933, the patient receiving a total of 1193 r. in twenty-two sittings. The apparatus was arranged as in Case 1 except that an increase of the milliamperage to 6 raised its output to approximately 54 r. per hour. An additional small amount of therapy totalling 180 r. was administered between July 22 and July 29 1935 in six sittings.

Course Reference to figure 2 makes clear the effect of the therapy on the blood picture during the treatment period and during the three succeeding years. All symptoms disappeared, there was a considerable gain in weight, and the spleen decreased in size. At the present time the patient feels perfectly well.

COMMENT

From the previously reported cases of polycythemia vera treated by "spray therapy" and from the two recorded here, it can be stated that this type of irradiation is definitely superior to the therapeutic agents in common use. Rontgenotherapy through small fields has not demonstrated its practicability as a routine measure. Dangerous drugs, such as phenylhydrazine and arsenic, require constant supervision and cautious administration, even then they often give rise to gastrointestinal disturbances, jaundice, or skin eruptions. Phlebotomy, an unpleasant procedure at best, not only must be performed at frequent intervals, but on occasion is ineffective. And as for daily stomach washes which have been recently suggested, one can only agree with Publius Syrus "There are some remedies worse than the disease." "Spray therapy", on the other hand, when administered in small doses over long periods of time has an astonishingly prolonged depressant effect on the blood-forming organs, produces no disturbing clinical symptoms, and may be given without interruption of the patient's daily work. For these reasons, therefore, I believe it to be the treatment of choice in polycythemia vera.

ERYTHROBLASTIC ANEMIA (COOLEY)

Hereditary erythroblastic anemia (Cooley), a pathologic entity manifesting itself in certain infants of Mediterranean parentage, has some histologic points in common with polycythemia vera. Although treated unsuccessfully in the past with rontgen rays through limited fields, prior to the autumn of 1935 it had not been, to my knowledge, subjected to a trial with "spray irradiation". When, therefore, a characteristic case of this curious malady entered the hospital and was sent to the X-Ray Department for an opinion as to the advisability of rontgenotherapy, the hope was entertained that if sufficient depression of the hematopoietic organs could be brought about, the continued escape of immature nucleated red blood corpuscles into the peripheral blood stream might be prevented. It was with this object in view that "spray therapy" was begun.

Through ignorance of the optimal dosage in this condition, the treatment went far beyond the desired result and produced an overwhelming, acute bone marrow depression. The leucocytes fell to 500 per cu mm and the platelets almost disappeared from the blood stream. There was an accompanying purpura and an alarming series of epistaxes,—the latter necessitating repeated blood transfusions. When this critical period had passed and the leucocytes and platelets had reappeared in the peripheral blood in more normal numbers, the circulating red blood corpuscles rose gradually but steadily

and after some weeks reached a higher level than had been observed at any time prior to irradiation. The amelioration, too, of the child's general condition seemed even more marked than the improvement of the blood picture. Thus the final clinical and hematologic effect of "spray therapy", while perhaps not so striking in this disease as in polycythemia vera, seemed encouraging enough to warrant recording the case.

CASE 3 Erythroblastic Anemia (Cooley)

M P, seven year old American born boy, of Italian parentage, entered the hospital September 5, 1935 complaining of pallor and weakness.

Present Illness The patient had never been well or strong since birth, and had always appeared abnormally pale. At the age of five and a half years, eighteen months prior to entry, the mother became aware that his pallor was increasing and that his strength was failing. Although in the year just past the boy had attended school, he had not felt well enough to participate in games with his play mates and complained that climbing one flight of stairs tired him out. The mother further testified that his interest in food had almost vanished, that his abdomen was gradually enlarging, and that his general condition was becoming progressively worse.

Family History Two sisters of the patient have erythroblastic anemia and are being observed at the present time in the outpatient department of the Massachusetts General Hospital. Three other sisters appear to be well.

The *past history* revealed no facts of importance.

Physical examination showed a well-developed and nourished boy with sallow complexion, pale mucous membranes, prominent eyes, and Mongoloid facies. He seemed chronically ill. There was slight icterus of the sclera. The chest, although barrel in type, gave no abnormal signs when percussed and auscultated. A loud systolic murmur (? hemic) could be heard over the entire precordium. There was a marked enlargement of the abdomen. The liver edge was palpable 7 cm below the costal margin, and a visible and palpable spleen with a smooth, firm surface extended to the level of the iliac crest. The body weight was forty pounds.

Laboratory Findings Nothing abnormal was found in the urine. Blood examination showed red blood corpuscles 2,540,000 per cu mm, hemoglobin (Sahli) 28 per cent, polymorphonuclears 56 per cent, lymphocytes 25 per cent, normoblasts 15 per cent, hematoblasts 2 per cent, unclassified cells 2 per cent. The erythrocytes exhibited extreme variation in size and shape, with many tailed forms, microcytes, macrocytes, stippled and polychromatophilic cells, platelets somewhat decreased. The icterus index was 5, the bleeding time five minutes. The blood Hinton test was negative.

X-ray studies showed bony changes in the skull, pelvis and lower extremities characteristic of erythroblastic anemia.

"Spray therapy" was begun on September 10 and completed on September 25, 1935, a total of 360 r being given in fourteen sittings. The apparatus was that used in the treatment of the first two patients, but so arranged that approximately 40 r per hour (measured in air) was received by the patient.

Course When the crisis (referred to earlier) had passed by, the patient's general condition improved in a manner paralleling the betterment of the blood picture. Figure 3 shows the return of the leuco-

cytes to normal the augmentation of the red blood count and the reduction in the absolute number of circulating nucleated red cells. The spleen decreased in size to a considerable extent and subjective symptoms disappeared. At present the child though still somewhat pale is bright and active, is gaining weight, attends school without fatigue and plays with gusto like any normal boy of his age.

COMMENT

This single case of erythroblastic anemia treated with "spray therapy" neither invites lengthy discussion nor warrants generalizations. It does demonstrate, however, that irradiation by this method has a rather marked depressant

effect on the erythroblastic anemia is presented here with the hope that further observations will be made.

CONCLUSIONS

- (1) "Spray x ray therapy", consisting of 1000 r given over several weeks time produced remissions lasting three years in two cases of polycythemia vera.
- (2) "Spray x ray therapy" in small doses in one case of erythroblastic anemia brought about favorable changes in the blood picture and improved the patient clinically.
- (3) This form of treatment appears to be the

FIG. 3

action on the rapidly proliferating erythroblasts in the bone marrow, and that with the consequent lowered rate of hematopoiesis fewer immature cells appear in the peripheral blood, an increased number of erythrocytes reach the blood stream and a definite clinical improvement takes place in the patient. It is of course, too early to comment on the lasting effects of the treatment, or on the frequency with which it should be repeated. Obviously the dosage used in this case was administered at too rapid a rate. Doses of from 10 to 20 r given at five day intervals might possibly produce beneficial results without such a marked effect on the leucoblasts and megakaryocytes. However that may be the result of "spray therapy" in one

case of choice in polycythemia vera and deserves further trial in erythroblastic anemia.

CERTAIN RELATIONS BETWEEN THE PARATHYROIDS,
THE HYPOPHYSIS AND THE PANCREAS*

BY BERNARDO A HOUSSAY, M D †

THE present paper will deal only with the manner in which the hypophysis and the pancreas can influence the structure and function of the parathyroids, rather than attempt to consider all of the many relationships which may exist between these glands or their secretory products. It may be noted here that the parathyroids, due to their small size, are frequently overlooked in postmortem examinations, also the microscopical alterations may be passed by, as frequently they are not easy to interpret. These facts explain to a certain extent why the histophysiology of these glands is less well known than that of others.

In 1930 Lascano Gonzalez, in our Institute, found pronounced lesions in the parathyroids of dogs whose pituitary and pancreas had been removed^{37 38 42}. This finding led us to study the microscopical aspect of the parathyroids and also the blood calcium of (a) hypophysectomized, (b) pancreatectomized and (c) hypophysectomized-pancreatectomized dogs.

THE PARATHYROIDS IN PITUITARY INSUFFICIENCY
Morphology The development and the maintenance of the normal structure and function of the endocrine glands (thyroids, gonads, adrenal cortex, parathyroids, thymus, etc.) are conditioned by the anterior pituitary, and hypophysectomy results in abnormal changes. In the case of the parathyroids hypophysectomy is followed by regressive lesions which can be seen microscopically, but it is difficult to determine whether the total mass of parathyroid tissue is reduced. Smith⁷⁹ found a diminution of the total amount of epithelial bodies in hypophysectomized tadpoles, but apparently there was no marked alteration in their structure. Smith⁷⁹ stated that atrophy of the parathyroids occurred in hypophysectomized rats, but in a later paper⁸⁰ he did not mention this condition, and Collip¹⁸ was unable to confirm the observation. In the subtotally hypophysectomized hen no modifications have been found,⁸¹ and in the hypophysectomized rabbit there are only slight changes, mainly a decrease in the size of the cells.⁸² Livon and Peyron,⁵³ Aschner,⁴ and Collip,¹⁸ saw no changes in the parathyroids of hypophysectomized dogs, on the other hand Koster and Geesink⁴⁷ mention having found these glands atrophied, but give no further data on this subject.

We have been unable to find any reports on

*Harvey Lecture delivered at the New York Academy of Medicine January 16 1936

†Houssay Bernardo A—Professor of Physiology Faculty of Medical Sciences University of Buenos Aires 1919—For record and address of author see This Week's Issue page 946 Issue of May 7

the structure of the parathyroids in human cases of pituitary insufficiency.

Lesions of the parathyroids have been reported in several papers published from our Institute since 1930. Up to date these glands have been examined in forty-two normal dogs, forty-six hypophysectomized, three hypophysectomized-thyroidectomized and in sixteen with lesions of the *tuber cinereum*.

The parathyroids of the normal, castrated controls have a massive, reticular or lobulated structure. The cells are polygonal or globular and the majority have a clear or only slightly granular protoplasm. In some glands, especially near the surface, groups of dark staining nuclei are found so closely packed together that no protoplasm can be seen around them (Synctium-ähnliche Zellgruppen). The connective tissue is scarce and in it are seen very fine blood vessels.

The first alterations occurring in the parathyroids of hypophysectomized dogs consist of the following phenomena: the cells decrease in size, the protoplasm becomes dark and granular, and its borders are no longer clearly marked, the nuclei are also reduced in size and the cells are more closely packed, so that they separate from the connective tissue stroma. This gives the structure of the gland a trabecular or cord-like aspect. Later the protoplasm atrophies and finally disappears almost completely, leaving the nuclei in rows or heaps. It is important to note that these modifications are found only in certain parts of the gland, e.g., at one of its poles or sides. In the most advanced degree the protoplasm disappears and only rows of nuclei are left, the meshes of the connective tissue stroma become prominent, and the blood vessels are dilated and sometimes surrounded by a fibrous sheath. In parts of the gland the degeneration of the epithelial cells may be so complete that acellular structureless zones of irregular dimensions and of granular aspect are formed, these stain a rosy violet color.

These alterations are not uniformly distributed, so that in any one animal some of the glands may be almost normal while others may show severe lesions. In the same gland normal and modified regions are to be found side by side. The morphological changes first appear five to fourteen days after hypophysectomy, they then spread and finally become stabilized. The following degrees may be differentiated (figure 1)

(a) *Slight* uniform cellular atrophy, few groups of closely packed nuclei, trabecular structure (Figure 2A)

FIG. 1.

Sections through the parathyroid glands of dogs to show the normal structure, A, and the different degrees of alteration following hypophysectomy: minimal, B; slight modification, C; medium, C and intense, D.

- (b) *Medium* large groups of closely packed nuclei, disappearance of numerous cells trabeculae of cord like structure
- (c) *Intense* numerous groups of closely packed nuclei, disappearance of many cells, cord like structure, thick connective tissue trabeculae (Figure 2B)
- (d) *Very intense* numerous groups of closely packed nuclei, large fields without cells, cord like structure abundant connective tissue numerous and large blood vessels (Figure 2C)

The lesion consists of a simple progressive atrophy of the cells with pyknosis and slow disintegration of nuclei. The decrease and retraction of the parenchyma make the connective tissue become more apparent. There is no reduction in the blood supply, on the contrary the blood vessels are large and numerous. There is no granular fatty or colloidal degeneration. There are no signs of compensatory hyperplasia. The most characteristic features are the global atrophy with darkening of the proto-

plasm, the accumulation of nuclei (in 66 per cent) the structureless zones and the great irregularity of the lesions which leave large parts of the gland with little or no alterations. This last fact explains why these animals do not have hypocalcemia. To interpret these lesions it is necessary to examine many cases, make numerous sections of each gland and acquire experience in the study of this tissue. If a careful examination is not made characteristic lesions obvious to a skilled observer may be passed over.

In our series of dogs the following alterations were found

	No of Animals	Slight	Medium	Intense	Very Intense	Total	Per Cent
Controls	42	4	—	—	—	4	0.5
Hypophysectomized	46	16	10	4	—	30	6
Hypophysectomized thyroidectomized	3	—	—	—	1	1	100
With tubercular lesions	16	2	3	—	—	6	3*

We have not been able to counteract these effects by the administration of anterior pituitary

tary lobe extract, though it has been tried in many cases. It is possible that the doses employed were not sufficient or that the activity of the extract was inadequate.

Calcemia In spite of the lesions in the parathyroids the plasma calcium was normal in the forty-seven hypophysectomized dogs so far studied in our Institute,^{26 41 56 57 60*} the average being 10.67 Mgm per 100 cc in the operated and 10.7 Mgm per 100 cc in the controls. In rats also normal values have been found.^{17 84} In two pigeons there was a slight decrease.⁷¹ In rabbits hypophysectomy is followed by a slight increase,⁵⁰ but irradiation of the pituitary sufficient to damage the gland does not alter the blood calcium.¹⁰ The toad *Xenopus levis* has a low blood calcium after extirpation of the principal lobe of the pituitary.^{13 35 73} and after gonadectomy.

Parathyroid extract increases the blood calcium of hypophysectomized rats⁶ and pigeons¹ to the same degree as it does in normal controls. It also produces a similar proliferation of osteoblasts and new bone formation in hypophysectomized rats as in normal controls.⁷⁶ Hypophysectomized rats however, show a tendency to a negative calcium balance, which is counteracted by growth-promoting pituitary extract.⁶⁸ On the other hand, the thyrotropic extract^{4 68} and thyroid administration increase the fecal excretion of calcium with the rise in the total metabolism.

THE PARATHYROIDS IN HYPERPITUITARISM

Parathyrotropic action of anterior pituitary extract Anselmino, Hoffmann and Herold³ have shown that anterior pituitary extract produces a considerable enlargement of the parathyroids in rats. There is hyperemia, increase in the number and size of the clear cells, decrease of the dark cells and disappearance of oxyphilic cells.[†] The same effect is obtained with the alcoholic precipitate of pregnancy urine, which has no thyrotropic activity. Hypertrophy and hyperplasia of the parathyroids have also been obtained in rabbits by the injection of pregnancy urine (Hertz and Kranes, 1934). We have seen this occur in less than half of the dogs injected with anterior pituitary extract (14 Gm per Kg per diem of fresh bovine anterior lobe for one week). An increase of the blood calcium lasting several hours has been observed in the dogs injected with this extract, but it does not occur if the thyroids and parathyroids have been removed.^{3 34 56 57 83†} The

*In two hypophysectomized dogs Koster and Geesink⁴¹ found a lower blood calcium than in their control animals. Since the values in the latter were 13 to 14.2 Mgm per 100 cc the observations are hardly significant. Nishida⁶⁰ found 10.41 Mgm in hypophysectomized dogs and 0.97 Mgm per 100 cc. in the controls.

†Anselmino and Hoffmann have had the kindness to send me their microscopical preparations.

‡This has also been found in the cat⁷ and in *Xenopus levis*⁷⁴ but in the rat there is no rise in the blood calcium following this treatment.

parathyrotropic factor has not been completely separated from other hormones but it is known that it is not ultrafiltrable and that it is destroyed by boiling.

The gonadotropic extract aggravates tetany and decreases the blood calcium of thyro-parathyroidectomized bitches, due to the increased secretion of estrin.²⁰

Hyperparathyroidism In seventeen out of 101 published cases of hyperparathyroidism an enlargement of more than one of the parathyroids has been reported. This fact has led to the belief that a stimulating action of the anterior pituitary may be a factor in the etiology of these cases.¹ Of special significance is the finding by Hertz and Albright that the injection of urine from patient with multiple parathyroid hyperplasia is capable of producing parathyroid hyperplasia in rabbits. Urine injection from cases of parathyroid adenoma does not produce this change.

Human hyperpituitarism In cases of acromegaly some observers have seen enlargement^{15 16 17} or adenomas^{1 21 22} of the parathyroids. Cushing and Davidson²³ noted a marked proliferative activity in one case and parathyroid adenomas in two others. In various postmortem examinations of acromegalies, abnormalities of the parathyroids have been reported. In one curious case of chromophobe adenoma of the pituitary Lloyd²⁴ found a simultaneous enlargement of the parathyroids and of the islets of Langerhans. In Cushing's disease cervico-dorsal kyphosis forms part of the syndrome. Osteoporosis and decalcification have been reported in fourteen out of twenty-four cases with postmortem examination in the literature. In nine of the fourteen cases collected by Cushing²⁵ there were spontaneous fractures, and osteomalacia was present in six.

The condition of the parathyroids is mentioned in fourteen of the twenty-four cases which we have found reported with a postmortem examination. In three cases there was an adenoma,^{21 22 26} in three the glands were enlarged,^{20 40 60} in six they were normal,^{2 16 19 41 73} and in one they were atrophied.²² Lipomatosis associated with other lesions was present in three of these cases and unassociated with other lesions in twenty others.^{20 41 42 60 7 73 77}

Cushing²⁵ believes that the basophilic adenoma of the pituitary produces a state of hyperparathyroidism which in its turn causes the bone lesions. Hoff,²² on the other hand thinks that in his case the pituitary adenoma was secondary to the hyperparathyroidism. Cushing's opinion meets with various objections. In most of the cases studied up to now lesions due to parathyroid hyperfunction have not been demonstrated. The bony lesions differ from those of

hyperparathyroidism, similar bony lesions have been found in cases of primary hyperinterrenalism. The blood calcium and inorganic phosphorus have been found to be normal, or the calcium slightly diminished and the phosphorus slightly increased.^{6 7 9 2 43 46 51 74 81} The negative calcium balance observed by Anb in one of Cushing's cases, is common to various bone diseases.⁶

In one of Cushing's cases Anb observed a marked amelioration of all symptoms including those related to the skeletal system following irradiation of the hypophyseal region. The negative calcium balance was also diminished.

THE PITUITARY AND PARATHYROID TETANY

Gaselli, in 1900 reported that extirpation of the pituitary in dogs suffering from tetany due to parathyroid insufficiency caused a more rapid death without alteration of the symptoms. We removed the thyroids and parathyroids in eight hypophysectomized dogs and found that they developed tetany and died similarly to normal dogs which were thyro-parathyroidectomized.

Extract of the whole pituitary gland or of the posterior pituitary can temporarily calm the tetany^{11 28 44 54 66} after an initial exacerbation of the symptoms. The mechanism of this action is not clear since these extracts do not prevent the reappearance of attacks of tetany or the lethal termination of the condition. We could neither prevent nor cure tetany in thyro-parathyroidectomized dogs nor prevent the fall in blood calcium, by injecting large doses of an alkaline pituitary extract intraperitoneally for two to three days before or after the onset of tetany.

THE PARATHYROIDS IN PANCREATIC INSUFFICIENCY

Morphology With R Sammartino we have studied the parathyroids of twenty-nine totally pancreatectomized and eight partially pancreatectomized dogs. After one to three days with no insulin the cells of the parathyroids become vacuolated and appear large and clear (Figure 3). The vacuoles appear first near the connective tissue trabeculae, following which they increase in size and coalesce. Later the protoplasm huddles and disintegrates the nuclei come closer together and form rows contiguous to the trabeculae, and the gland assumes a tubular aspect. In some cells there are also nuclear changes.

When the condition is more intense, the gland decreases in size and presents either an insular or a cord-like structure due to the decrease in the volume of the cells and the approximation of the nuclei to each other. Some of the latter become pyknotic.

These lesions occur early, are intense and affect the whole gland (Figure 4). The syn-

cytium like accumulations which occur frequently in hypophysectomized animals (66 per cent) are as infrequent in the pancreatectomized (two out of twenty nine) as in the normals (10 per cent). In contrast with the hypophysectomized animals where there is a global atrophy of the cells in the pancreatectomized there is vacuolization and disintegration of the protoplasm

Calcemia The determinations made in our Institute on forty pancreatectomized dogs by Varenzi and Gerschlman²² show that blood calcium decreases from the normal level of 10.115 Mgm. per 100 cc. of plasma to 8.2105 Mgm. in four days and to 7.396 Mgm. in seven days. Determinations on twelve dogs showed that in two it fell to 9.293 in six to 8.188 and

C Magnification as in B showing clear and vacuolated cells

in four to 7376, the average being 82 Mgm per 100 cc plasma. The decrease in blood calcium depends on the intensity of the diabetes and is less marked and occurs more slowly or may even be absent if the pancreatectomy is subtotal.

There is also an increase in the inorganic phosphorus which may reach 14 Mgm. per 100 cc of plasma (the average is 8.8 Mgm.), and a decrease in the sodium and chlorides the alkaline reserve and the total CO₂ (average 31.9 cc.).

Treatment with insulin prevents the decrease in blood calcium or causes it to rise if already diminished. We did not, however, obtain a return to the original level in our experiments nor did the histological appearance of the parathyroid glands become normal. This was probably due to the fact that the blood sugar remained elevated and the glycosuria did not completely disappear.

The injection of parathormone caused a rise in the blood calcium (up to 15 Mgm. in one case), just as in normal dogs.

Extract of anterior pituitary lobe was injected into the pancreatectomized animals but it resulted in an intensification of the diabetes leading to coma and death in one to two days with a marked hypocalcemia (averaging about 7 Mgm. and in one case falling to 3.9 Mgm. per 100 cc plasma).

The hypocalcemia and the changes in the parathyroids do not occur in dogs with intact pancreas under conditions of simple fasting or after the administration of phlorizin for a week either during fasting or with feeding, even though there is intense glycosuria and loss of weight.

Human diabetes. Kraus¹⁸ has observed parathyroid lesions in some young diabetes the principal cells being poor in protoplasm with dark nuclei giving the appearance of lymphoid tissue. These are the cytological signs of atrophy and functional insufficiency. In adults there is less cellular alteration. According to Jansen¹¹ the blood calcium is normal in diabetes except in certain isolated cases which have ketonuria. In these it may fall to 8.2—8.5 Mgm. per 100 cc (as compared with 11.5 Mgm. in normals). He attributes this fall to a loss of calcium in the feces due to the acidosis.

It is premature to attempt to connect the arthritis, catarrhs, bone alterations etc., of diabetes with an alteration in the calcium metabolism and parathyroid dysfunction.

THE PARATHYROIDS IN HYPOPHYSECTOMIZED-PANCREATECTOMIZED ANIMALS

Morphology. We found with Sammartino that the parathyroids in nine hypophysectomized pancreatectomized animals presented both

the lesions found in hypophysectomized and those seen in pancreatectomized animals separately (figure 5). In six such preparations there were abundant syncytium like groups of cells and structureless, degenerated basophilic zones. At the same time in extensive areas sometimes occupying the whole gland, there was vacuolization of the cells the latter becoming big and vesicular with transparent protoplasm. This is the appearance of the parathyroid in the early stages after pancreatectomy, and probably the lesions do not develop further as the diabetes is not so intense in the hypophysectomized pancreatectomized animals.

Calcemia. The calcemia of these animals is lowered as in the pancreatectomized, but the fall occurs more rapidly. Thus, in eight cases after four days, Marenzi and Gerschman²¹ found blood calcinms of 8.10, 7.6, 8.6, 9.2 and 7.5 Mgm (average 8 Mgm.) per 100 cc. The inorganic phosphorus rises less (average 5.7 Mgm.) than in the pancreatectomized animals, the alkaline reserve does not change greatly (average 54) the sodium and chlorides decrease, and, because of the hypophysectomy blood potassium also falls.

GENERAL SUMMARY

In the presence of pituitary insufficiency in the dog there is cellular atrophy in the parathyroids with foci or zones of accumulated nuclei, which simulate cords and occasionally acellular basophilic areas. These changes may be the result of general nutritive alterations or of the lack of parathyrotropic hormone.

The blood calcium is not altered probably because the parathyroid lesion is partial or incomplete.

Anterior pituitary extract increases the size of the parathyroids and their content of clear cells. It also raises the blood calcium but this rise does not occur when the parathyroids have been removed.

The theory has been put forward that an excess of parathyrotropic hormone may be the cause of human hyperparathyroidism but more observations are necessary for confirmation.

The state of the parathyroids in hyperparathyroidism has not been studied carefully in large series of cases. Adenomas have been found in cases of acromegaly and adenomas or enlargement in some cases with Cushing's syndrome but in general the parathyroids are normal or lipomatous in these diseases. Whether the origin of the osteoporosis in Cushing's syndrome is due to hyperparathyroidism or to the adrenals or to some other cause is not certain.

Pituitary extracts do not prevent or cure the hypocalcemia and tetany due to parathyroidectomy and the results following thyro-parathyroidectomy are similar in hypophysectomized and in normal dogs.

In pancreatic insufficiency in the dog there is vacuolization, liquefaction and later protoplasmic disintegration of the cells of the parathyroids. The nuclei remain isolated, forming tubes, rows or islets. In three to seven days the blood calcium is lowered to levels between 7 and 9 Mgm per 100 cc of plasma and the blood phosphorus increases. Insulin prevents the decrease of the blood calcium, but, in experiments at our Institute, late treatment with insulin, after the fall in calcium had occurred, was not completely effective in raising it to normal nor was the normal histological appearance of the glands restored. It should be noted, however, that in these experiments overnight hyperglycemia was not controlled and further observations are therefore necessary.

In hypophysectomized-pancreatectomized dogs the lesions due both to hypophysectomy, and to pancreatectomy occur side by side. The lesions due to pancreatectomy are not so severe as in dogs in which the pancreas alone has been removed though the hypocalcemia is similar in the two groups.

The proper functioning of both the pituitary and pancreas is necessary in order to maintain the integrity of the parathyroids. Insufficiency of one or the other of these glands results in different changes. Although proof for the theory is incomplete it may be suggested that in hypophysectomized animals there is a lack of a parathyrotropic hormone, which may or may not be a specific one, whereas, in the pancreatectomized animals, the changes may be due to nutritive disturbances associated with the diabetic condition.

THE HYPOPHYSIS AND RESISTANCE TO INTOXICATIONS,
INFECTIONS AND TUMORS*

BY BERNARDO A. HOUSAY, M.D.†

INTRODUCTION

In the early days of the study of endocrine glands it was thought that they possessed antitoxic functions. The disorders due to glandular insufficiency were attributed to toxins arising from metabolic processes or absorbed from the intestine. The toxins were thought to accumulate in the body because of the fact that they were neither destroyed in the gland itself nor neutralized in the blood or tissues by the glandular secretions. This antitoxic theory has deservedly collapsed since the supposed toxins have not been isolated nor has their existence been demonstrated in a way that would explain the functional disorders of the different glandular insufficiencies. On the other hand several hormones are now known and some have been isolated in a pure state. These hormones prevent or cure the metabolic and their functional symptoms of the respective glandular deficiencies and if given in excess can produce signs of glandular hyperactivity.

The abandonment of the idea of an antitoxic function of the endocrine glands in favor of a hormonal function, has resulted in a shift of interest which reigned about a quarter of a century ago, in the study of the relation between the endocrine glands and immunity. Nevertheless this problem is of importance both in general pathology and immunology.

Very little work has been done on the pituitary from this point of view, probably because there are not many who have access to hypophysectomized animals and also because it has been only recently that active extracts have been obtained, even though these latter are still very impure and complex.

The pituitary may play a part in immunity and resistance to intoxications in various ways (1) By direct antitoxic action (intra or extra glandular). (2) By its action on other endocrine glands. Since the anterior pituitary regulates the thyroids, adrenal cortex, gonads, parathyroids, etc. the activity of these organs is decreased in pituitary insufficiency and increased when this gland is overactive. (3) By action on the hematopoietic or phagocytic organs e.g. the spleen, thymus, etc. (4) By affecting metabolism and vasomotor reactions, the pituitary influences the resistance of the

body to agents which lower the blood sugar and to those which lower the blood pressure. The action of such agents is intense in hypophysectomized animals. For the first of these mechanisms there is no proof but the second third and fourth occur in cases to be mentioned later.

Extirpation and destructive diseases of the pituitary produce an experimental or pathological deficiency in those functions which are directly performed by the gland. This deficiency is compensated for or may even be overcompensated for by restitution (implantation of the gland or injection of extracts). Hyperfunction (experimental or pathologic) produces opposite and different symptoms from those of glandular insufficiency. When the action is in direct, through the effect on another gland (e.g. thyroid, adrenal cortex, etc.) disturbances occur which are common to pituitary insufficiency and to insufficiency of the said gland. These disturbances are corrected both by preparations of the affected gland (thyroid, adrenal cortex, etc.) and by extracts of the pituitary which are capable of stimulating the gland (thyrotropic, adrenotropic, etc., pituitary extracts). The last mentioned extracts are effective only when the respective gland is present and capable of responding to stimulation.

Specific neutralization of toxins or destruction of germs by the pituitary or its secretions has not yet been proved. There are however, several ways in which it could take a part in immunity. Thus it might increase the general resistance of all the body cells or perhaps of only certain tissues to harmful agents; it might also enhance the capacity for antibody formation, or for the fixation and destruction of germs and toxins. Up to the present it is only possible to say that endocrine glands appear to play a certain rôle in immunity in an indirect way by means of their metabolic functions or other nonspecific activities, such as stimulation of phagocytosis, or maintenance of the integrity and resistance of the skin, the mucous membranes, etc.

THE PITUITARY IN INFECTIONS AND INTOXICATIONS

Infective Lesions of the Pituitary

The pituitary may be the site of infectious lesions, as such as septal infarcts and abscesses, which in their ultimate evolution give rise to atrophy or fibrosis, the appearance of the syndromes of pituitary insufficiency and to Simmonds' hypophyseal cachexia, etc. Circumscribed tuberculous lesions affecting the

Received December 9, 1935 at Stanford University School of Medicine.

Bernardo A. Housay, M.D., Professor of Physiology, Faculty of Medical Sciences, University of Buenos Aires, 1915. For record and address of author see "This Week's Issue," page 946, 1st issue, May 7.

Includes the early publications of 1916, 1917 and 1918. Numerous studies on these subjects have been performed in our Institute from 1920 to the present date.

pituitary as well as metastatic lesions from distant foci and invasion from neighboring tissues have been described^{1 5 10 20 25 35 42 44 48 50 51 52 54 63 64 58 59 74 77 84 88 etc} Syphilis^{1 8 9 10, 15 21 22 24 30 32 37 45 46 48 49 51 50 52 65 67 68 59 73 75 80 81 82 83 85 87 etc} may produce gummatous or fibrous lesions in the adult and congenital lesions in children. The *Treponema pallidum* has been found in the latter (Dupré, Sabiazés). *Echinococcus*^{31 40 72} and *cysticercus*^{1 49} infections of the pituitary have also been known to occur. For further details the articles of Kraus² and Berblinger¹ should be consulted.

The Pituitary in Human Infections

The pituitary has been studied macroscopically and, what is more important, microscopically in various general infections in human beings, such as tuberculosis,^{10 26 48 50 65 77 79 etc} typhoid,^{25 28 41 77 79 etc} diphtheria,^{10 23 28 31 48 50 79 etc} smallpox,^{77 etc} erysipelas,^{77 etc} scarlet fever,^{56 etc} tetanus,^{77 79 etc} the septicemias,^{11 19 77 79 etc} intestinal obstruction,^{77 etc} pneumonia,^{25 28 77 79 etc} rabies,⁵⁷ typhus,^{77 79 etc} encephalitis lethargica,⁴¹ bronchopneumonia,^{25 28 77} and also in distemper in dogs.²⁴ The older observations were made with imperfect staining techniques and it was believed that in acute infections an initial hyperactivity,^{25 79} followed later by exhaustion and hypoactivity (Dehille) occurred while in chronic infections there was only hyperactivity. The cytological changes have been described more accurately by more recent workers.

Modifications of the Pituitary in Experimental Infections and Intoxications

A number of descriptions have been given of the histological changes occurring in the pituitary of animals which had been subjected to various experimental procedures. The procedures used included the following: inoculation with diphtheria bacilli or toxins,^{4 10 89 77 86 etc} typhoid bacilli,⁷⁷ staphylococci,¹¹ streptococci,¹¹ and tubercle bacilli,¹¹ also with the toxins of worms^{12 71 etc} and with eel-serum,³⁰ ligation of the common bile duct,³⁰ the intestine³⁰ and the ureter,³⁰ injection of pilocarpine,^{39 77 etc} alcoholic poisoning⁶⁰ and production of uremia.^{1 25 39 54 56 76 77 etc} Solely on the basis of interpretations of the histological changes, it has been supposed that there is an initial hyperactivity leading to exhaustion and functional insufficiency.

Functional Changes of the Pituitary During Infections

The functional changes in the pituitary during infections and intoxications are not accurately known, since no method is available by which the pituitary secretion can be measured

in the blood, neither has the relation between the histological aspect of pituitary glands and their activity, as demonstrated by implantation or by injection of extracts made from them, been investigated. Del Castillo, in unpublished work, found that there was no change in the gonadotropic effect of the pituitary of rats inoculated with *Trypanosoma equiperdum* on the immature ovary. The animals were killed eight to twelve days after inoculation with a strain that killed the majority of inoculated rats in ten to twelve days.

Azam⁷ and Dehille,²⁵ pupils of Renon, attribute the tachycardia, hypotension, insomnia, anorexia, sweating, etc., of acute infections to pituitary insufficiency, although it is by no means certain that these are the symptoms of such insufficiency. The fact that pituitary extracts produce some rise in blood pressure, strengthen the beat and slow the rate of the heart, increase diuresis, etc., is not enough proof to support their theory.

It has been thought possible that the exaggerated increase in height of young typhoid convalescents might be due to pituitary hypersecretion,^{11 24} though, of course, it might also be due to the direct action of the typhoid bacilli or of their products on the cartilage. Sometimes tuberculous children grow very rapidly when they reach adolescence and show signs of progeria, but it has not been shown whether these symptoms can be attributed to hyperpituitarism or to a toxic action of the disease on tissue growth.^{34 53} Neither can it be affirmed that the sexual retardation and amenorrhea of tuberculous adolescents are due to overactivity of the pituitary.⁵³

RESISTANCE OF HYPOPHYSECTOMIZED ANIMALS TO INFECTIONS AND INTOXICATIONS

Sensitivity to Anesthetics and Hypnotics

Chloralose anesthesia is not well tolerated by hypophysectomized dogs.¹⁵³ In 1932 we started to use ether instead of chloralose and the mortality in the first week after operation dropped from 75 per cent to 15 per cent. On the other hand it is necessary to use a larger dose of chloralose than the usual one to anesthetize hypophysectomized or thyroidectomized dogs which have been previously treated with thyroid (1 to 4 Gm. daily of bovine extract for four to six days). This is also true in the case of hypophysectomized dogs after treatment with anterior pituitary thyrotropic extract. Ether anesthesia, however, gives unsatisfactory results in hypophysectomized toads.

The hyperglycemia due to morphia is less marked in hypophysectomized toads than in the controls, and implantation of the glandular lobe increases it.¹⁵⁰ In the hypophysectomized dog this hyperglycemia is on the average higher

than in the controls, but the difference is not statistically significant.¹¹⁰ Ten hypophysectomized dogs presented similar symptoms to those seen in twenty controls when given a subcutaneous injection of 30 Mgm per Kgm of morphine chloride, one hypophysectomized animal, however, died two hours later in deep coma while another had convulsions and respiratory failure, but was saved by artificial respiration. These two animals were the only ones which had practically no rise in blood sugar. Diabetogenic anterior pituitary extract increases the hyperglycemia due to morphine in dogs.¹¹⁰

Sensitivity to Operations

Tadpoles deprived of the buccal pituitary anlage have a diminished resistance to unfavorable conditions.⁹⁹ Hypophysectomized toads and those whose glandular lobe alone has been removed, remain active and appear to be in good condition for about three weeks after the operation. Soon after this they become ailing and this disturbance increases progressively until death occurs.¹² In spite of their apparently good health, from the very beginning, they are killed by many operations (e.g. on the testes, thyroid glands, adrenals and even cloacal ligature) which are well tolerated by the controls.^{123, 112, 107} etc. If however these operations are performed five to ten days before the hypophysectomy many animals survive.

Smith¹¹³ stated, and it has been confirmed that hypophysectomized rats present a general physical impairment characterized by a lowered resistance to operative procedures although the wounds heal well.¹²³ Hypophysectomized rabbits also have a diminished resistance to surgical trauma.^{104, 105}

Hypophysectomized dogs are very sensitive to injuries, exposure and bad feeding. They readily become anorexic, which leads rapidly either to cachexia or death in hypoglycemia.^{100, 115} Nevertheless with care a large number can be kept alive, even after the removal of one or more other glands besides the pituitary (e.g., ovaries, thyroid and pancreas).

The hypophysectomized pancreatectomized animals, which have less hyperglycemia, glycosuria, azoturia and acidosis, live longer than the pancreatectomized animals with the pituitary intact, in which the diabetes is more intense. In the former group with an attenuated diabetes, the wounds suffer less from infection and heal even though no insulin treatment is given but they never do so well as the hypophysectomized animals with the pancreas intact.

Sensitivity to Infections

According to Aschner⁹⁰ hypophysectomized dogs have a diminished resistance to infections, being particularly sensitive to mange and Cushing¹⁰⁰ also states that hypophysectomized

dogs are more susceptible to infections and that their resistance is diminished. We have not confirmed this increased susceptibility having found that mange is readily cured by sulphur¹⁴¹ but we have noted that when infected or ill these dogs readily become anorexic, hypoglycemic or cachectic and die. The wounds of hypophysectomized toads (or those without the glandular lobe) are more readily infected and heal slowly and with difficulty (Magdalena Aubrun Pasqualini, etc.). Also their cutaneous glands are frequently invaded by cocci (Aubrun and Porto, unpublished). Hypophysectomized rats show the same sensitivity to caries of the molars as do the normal animals.¹⁰¹

Cushing¹⁰⁰ described acute or infectious processes as occurring in seven of his patients notably in those with a primary hyperpituitarism. There also seemed to be a definite susceptibility to infection in his cases of pituitary basophilism.¹¹⁰ Atkinson⁸ found that out of 1319 published cases of acromegaly only twenty had tuberculosis as well and that six of these died of the infection.

Sensitivity to Intoxications

There are four groups of toxic agents which are poorly tolerated by hypophysectomized animals, namely anesthetics, blood sugar reducing agents, blood pressure reducing agents and those agents which have intense adverse effects on thyroidectomized or adrenalectomized animals.

Blood Pressure Lowering Agents

The hypersensitivity to histamine and to other shock inducing agents pertains to this group.

Amphibians Removal of the pituitary does not alter the sensitivity of the frog (*Leptodactylus ocellatus*) to veratrine¹²¹ or of the toad (*Bufo arenarum* Hensell), twenty days after the operation to morphine, atropine, curare and veratrine.¹²¹

Rats Three or more weeks after hypophysectomy in the rat the toxic dose of cobra venom is only two thirds of that necessary to kill the controls.⁹³ The minimum lethal dose of histamine is halved if the hypophysectomy is total and there is an initial hypotension but is unchanged if only the posterior lobe has been removed and there is no hypotension.¹⁰⁴ According to Perla¹⁴¹ the toxic dose of histamine for hypophysectomized rats (one to ten weeks after operation), which show atrophy of the internal part of the adrenal cortex, may be one third or even only one fifth of that for normal rats. When a sufficiently large part of the anterior lobe is left there is no alteration in the adrenal cortex or in the sensitivity to histamine. Perla believes that the increased sensitivity is due to hypofunction of the adrenal particularly as

treatment with cortin increases the resistance to histamine, although it does not modify the adrienal atrophy

Putnam¹⁶² found that a dose of glycine which did not affect the controls caused a decreased metabolism and death in six to twelve hours in hypophysectomized rats

Dogs Feirer Zanchi¹¹⁸ injected several dogs with a suspension of dead typhoid bacilli. The eight controls survived but two out of six hypophysectomized animals died, one an hour after receiving 2500 million bacilli per Kgm, the other twenty-four hours after receiving 500 million per Kgm. This is not surprising since hypophysectomy in the dog produces a slight lowering of blood pressure and a slower recuperation of the normal blood pressure level after bleeding¹⁰¹. This slight hypotension has been observed in the rat¹⁰⁰ and is much greater in the toad¹⁷⁷. Braier¹⁰⁰ noted that injections of B. Coli vaccine caused a less marked rise of the basal nitrogen and creatinin excretion in hypophysectomized dogs, than in the controls but the rise of temperature was similar in both groups

Agents Acting Through the Thyroid

Anterior pituitary extracts, through their thyrotropic action, cause great sensitivity to anoxemia in rats, guinea pigs,¹⁴⁶ and mice¹⁹¹. This sensitivity is not observed when the thyroids have been previously extirpated¹⁴⁶. It may be remarked that hypophysectomized rats tolerate anoxemia more or less as the normal animals do (Chiodi and Raetti, unpublished)

The fall in body temperature provoked by novocaine is reduced or prevented in guinea-pigs¹⁹⁰ and anesthesia by chloralose is somewhat impeded in the dog, by treatment with thyrotropic pituitary extract

It is known that the resistance of the white rat to the toxic action of acetonitrile is increased by the ingestion of thyroid (Reid Hunt's effect). Injections of thyrotropic preparations of the anterior pituitary lobe produce a similar effect,^{173 170 178 170 190*} because they stimulate the thyroid to greater activity. This effect of anterior pituitary extracts has not been observed in thyroidectomized animals^{178 170}. The serum of men¹⁷⁵ and dogs¹²⁵ after treatment with anterior pituitary lobe increases the resistance of rats to acetonitrile, but the serum is without effect in the absence of the thyroid. Oehme, Paal and Kleins¹⁷⁰ believe that the active substance is other than the thyrotropic principle of the anterior pituitary, for it appears to be active *per os*, and does not cause histological changes in the thyroids. Posterior pituitary extract also increases the resistance

to acetonitrile, without stimulating the thyroids¹⁵⁴

Hypoglycemic Agents

In 1924 Magenta and I found that hypophysectomized dogs are very sensitive to the hypoglycemic action of insulin. Later, with Biasotti and Braier, we found that in these animals a number of different agents readily produce hypoglycemia, with severe symptoms such as convulsions and coma leading to death. This can be prevented by early treatment with glucose, posterior pituitary extract or adienalin, it being necessary sometimes to repeat the treatment. The hypoglycemia can also be prevented by treatment with anterior pituitary extract for two to three days. It should further be noted that hypoglycemic crises occasionally occur spontaneously in hypophysectomized animals, whether the pancreas is present or not. They are frequent during the secondary fall in blood sugar which follows the hyperglycemia of adienalin during fasting, and are constant after several days of fasting and also after the injection of phlorhizin or insulin.

Injection of phlorhizin produces fatal hypoglycemia in fasting hypophysectomized dogs¹³⁵ and in hypophysectomized toads¹¹³. This is prevented by feeding the dogs on a protein or carbohydrate diet, but not by fat diets^{17 181}. Treatment with alkaline anterior pituitary extract, before and during a fast of five to six days, prevents the hypoglycemia and death following phlorhizin¹³⁷. Fasting hypophysectomized dogs, after adienalin hyperglycemia, have an accentuated secondary hypoglycemia, giving rise to hypoglycemic crises^{100 102}.

Aschner⁹⁰ believed that although hypophysectomized dogs have a diminished resistance to intoxications, they tolerate subcutaneous injection of adienalin better than the controls since they do not develop local necroses and they show a lower glycosuria. Braier¹⁰⁰ injected adienalin intravenously (0.5 Mgm per Kilogram in twenty minutes) in fasting hypophysectomized dogs, and found during the first six to seven hours a slightly larger decrease in the excretion of nitrogen and urea than in the controls. There was also a lower hyperglycemia, with a marked secondary hypoglycemia, which gave rise to convulsions in three out of five cases, two of these were saved by treatment, but the other died during the night. When the animals were fed, the hyperglycemia was the same or greater than in the controls. In dogs and men suffering from pituitary insufficiency Lucke¹⁶² observed a much greater rise in blood sugar following adienalin, followed later however by a larger fall and a higher renal threshold. In hypophysectomized rabbits the hyperglycemia occurs more slowly and is not so great as in the controls^{120 150}.

*Riatti could not confirm this but his mice reacted very irregularly to acetonitrile

The extreme sensitivity of hypophysectomized animals to insulin was discovered by us.¹¹³ Doses, which in the controls cause very slight lowering of the blood sugar with no symptoms cause an intense hypoglycemia in the hypophysectomized animals with convulsions and coma invariably ending in death unless intense and repeated treatment is carried out. This extreme sensitivity to the hypoglycemic and toxic action of insulin has been observed in dogs,⁹⁴ 101 103 117 121, 1 2 143 144 165 16 151 etc. cats,¹⁶⁶ monkeys,¹⁻⁷ rabbits,¹⁰⁴ 105 1 9 157 156 187 166 and man,⁹¹ 168 1 6 16 165 etc. but apparently does not occur in birds,^{1 9} it is also observed in hypophysectomized pancreatetectomized dogs (Regan and Barnes,¹⁸³ Houssay, unpublished data). It does not occur in dogs with severe lesions of the basal or retro hypophyseal part of the tuber cinereum¹⁴⁴ or in rabbits with the midbrain excised.¹⁸⁰

According to Geiling and his collaborators the sensitivity to insulin is due to deficiency of the posterior pituitary lobe but on the basis of our experiments we attribute it to anterior pituitary deficiency. Extracts of the posterior lobe can, to a certain extent, counteract the hypoglycemia and its severe symptoms in the dog,^{122, 123} and toad,¹⁴⁶ though vasopressin may not be efficacious in the rabbit.¹⁰ Animals with inactivated adrenal medulla which are hypersensitive to insulin, can also be successfully treated with posterior lobe extract.¹²²

The protective action of the anterior pituitary lobe extract is very potent, far more so than that of the posterior lobe extract. It is able fully to counteract the sensitivity to insulin and also to raise the resistance both in hypophysectomized and normal toads,¹⁴⁶ dogs,¹¹⁴ 167 and rabbits.¹⁰⁴ The anterior pituitary extract requires one to two days to increase the resistance,¹¹⁴ and therefore is not efficacious in animals already in convulsions and coma.¹¹³

This protective action also occurs in thyroidectomized hypophysectomized animals (di Benedetto and Houssay etc.). The sensitivity of the thyroidectomized rabbits and dogs to insulin¹⁰¹ (Houssay etc.) is greatly increased if hypophysectomy is also performed. For this reason we can exclude the explanation that diminished resistance to insulin following hypophysectomy is due to hypothyroidism.

It has been thought that this diminished resistance might be due to adrenal insufficiency because adrenalectomized animals are hypersensitive to insulin.¹⁶⁰ 101 and in pituitary insufficiency there is some atrophy of the adrenal cortex. The following objections may be raised against this theory. Anterior pituitary extract has a diabetogenic action in pancreatetectomized

toads, in adrenalectomized toads and in dogs lacking the adrenal medulla. It also protects these latter from insulin. According to Barnes, Dix and Rogoff, hypophysectomized animals require more adrenalin to prevent convulsions than do those with denervated adrenals. They interpret this observation as showing that hypophysectomized animals do not liberate adrenin during insulin hypoglycemia. On the other hand Cope and Marks¹⁰⁴ demonstrated that there is adrenin secretion for which reason they believe that the anterior lobe of the pituitary maintains the glycogenolytic action of adrenin normal.

There are insufficient observations to draw definite conclusions regarding modifications of the sensitivity to insulin in the diabetes of acromegals. Some authors have observed an increase in the resistance to insulin,¹¹⁰ 162 168 123 etc. others have found it the same as in other diabetics,⁹⁴ 101 123 140 153 153 155 197 etc. and even hypersensitivity has been described.¹⁶⁰

Our opinion is that in pituitary insufficiency a hormone is lacking which plays an important role in carbohydrate metabolism, hypersensitivity to insulin is due to the absence of this hormone which acts as a stimulating agent for the production of glucose.

Antitoxic Action of the Extracts

Much work has been done to find out if pituitary extracts can neutralize poisons or increase the resistance of animals to these agents but the results are not conclusive. Delille¹¹² tried injecting pituitary extract and various poisons (potassium arsenate atropine mercury cyanide strychnine human urine) together and separately, but obtained no definite results. Marañon and Aznar¹⁷⁰ state that posterior pituitary lobe extract prevents the toxic action of strychnine in the guinea pig so that convulsions and death do not occur. These results have not been confirmed by our experiments.¹⁴⁰ Mariante¹⁷² stated that posterior lobe extract masked the toxicity of morphine, but this also was not confirmed by our experiments in guinea pigs and pigeons.^{121, 140}

Phagocytosis and Opsonins

There are a number of scattered observations on the relation of the pituitary to phagocytosis and opsonins of which the following may be mentioned. Carbon dioxide does not produce leucocytosis in hypophysectomized guinea pigs, but if these animals are treated with pituitary extract, they respond normally.¹⁰³ The injection of extract of horse pituitary causes a transient increase in the phagocytic power of the leucocytes and later a diminution.¹⁷¹ Injection of hypophysin increases the complement in the serum.¹⁶¹ Pituitrin lowers the opsonic index

*The commercial extract used by Lucke of unknown preparation, has posterior pituitary lobe properties. It has a immediate slight glycaemic action which does not occur in the absence of the adrenal.

against staphylococci and tubercle bacilli in rabbits¹⁹⁴

Parodi (unpublished work) in our Institute has found a marked decrease in the phagocytic powers of the polymorphonuclear leucocytes in the blood of hypophysectomized dogs, using Radsma's modified method he found that 50 ± 1.9 per cent of the leucocytes ingested starch in the controls, but only 20 ± 5.2 per cent in the hypophysectomized animals. Peritoneal injection of alkaline extract of anterior lobe greatly increases phagocytosis but this cannot be considered a specific action as extracts of muscle and kidney will also do this. It is possible that the diminished phagocytosis found in hypophysectomized animals is due to hypothyroidism.

Antibody Formation

Borchardt⁹⁸ states that injection of pituitum raises the agglutinating power of the serum in animals or men injected with typhoid bacilli. Cutler,¹⁰⁷ however, found an equal formation of these agglutinins in normal and in incompletely hypophysectomized guinea pigs, and also an equal formation of hemagglutinins and hemolysis on injection of chicken erythrocytes. He further showed that neither ingestion nor intra-peritoneal injection of pituitary extract altered the course of immunization.

Ferrer Zanchi¹¹⁸ in our Institute immunized four hypophysectomized dogs and five controls with doses of 2,000 to 5,000 millions of dead typhoid bacilli per Kgm of body weight. The agglutination curves and maximum titres were similar in both groups.

Savino,¹⁵⁰ also in our Institute, immunized five normal and seven hypophysectomized dogs with diphtheria anatoxin during twelve weeks. The individual titres of the sera tested every two weeks showed a more rapid immunization in the hypophysectomized animals, the serum of which always reached a higher final antitoxic value. The average was 38 ± 6.1 A. U. for the hypophysectomized compared with 26 ± 5.5 A. U. for the controls, a difference of 12.3 ± 2.6 A. U. This may be explained as due to hypothyroidism¹¹⁰ to hypersensitivity, to slower absorption of the anatoxin or to general nutritive changes.

In contradistinction to Jungeblut and Engle,¹⁻² Hudson Lennette and King¹⁴⁷ found that gonadotropic pituitary extract did not cause the appearance of any activity antagonistic to poliomyelitis virus in the serum of monkeys, nor did it increase the resistance of these animals to intracerebral inoculation.

THE PITUITARY AND CANCER

Tumors of the Pituitary—The pituitary frequently is the site of adenomatous proliferation or of true adenomas of acidophilic, basophilic, chromophobic or mixed types which give

rise to more or less specific symptoms. Malignant adenomas or adenocarcinomas may also occur. Besides these, angiomas, fibromas, teratomas, adamantinomas, etc., have been found. There is a special group of tumors known as tumors of the pituitary canal, which consist of craniopharyngiomas and teratomas.^{1 209 210 211 220 228 275 etc.} In addition, metastases from various origins occur in the pituitary.^{230 236 238 266 274 280 etc.} giving rise to certain symptoms (polyuria, etc.). When sarcoma is implanted into the gland in the rabbit it does not proliferate as much as in other tissues.²²⁷

The Pituitary in Cancerous Patients

Various histological^{1 201 215 233 236 261 268 274 279 280 etc.} changes have been described in the pituitary gland found at autopsy on cancerous patients, e.g., increase in the principal cells,²²³ increase²¹⁵ or decrease of the basophiles,²³⁸ increase in the weight of the gland and in the number of the eosinophiles,²⁸⁰ signs of hyperactivity of the anterior lobe, and of hypoactivity of the posterior.²⁷³

In rats with subcutaneous implantation of tumors there is an increase and vacuolization of the basophile cells of the pituitary, with enlargement of their Golgi apparatus. The changes are similar to those produced by castration, although the sexual cycle is not affected. If these pituitary glands are then implanted into immature rats it can be demonstrated that they have an increased gonadotropic activity.²²⁶ If the cancerous implantation is made into the uterus there is a larger increase of the eosinophile cells of the pituitary and less of the basophiles, and the pituitary appears like that of pregnancy or after the injection of estrin.²²⁶

Hypophysectomy and Cancer

Hypophysectomy before or after implantation of tumors causes a retardation of their growth in rats.^{109 202} but does not completely stop it,^{243 250 260} although it has been observed occasionally that shrinkage occurs and fewer of the implants take.^{244 262 263} There are also fewer metastases, but the resistance of the animals is diminished.²⁴⁴ In hypophysectomized rabbits also a diminished growth of implanted sarcoma has been observed,²²⁷ although with partial hypophysectomy teratocarcinoma may develop more rapidly than in the controls.²²⁴ Irradiation of the pituitary with x-rays diminishes the growth of cancer in rats.^{208 247} but it has not been proved that this treatment produces any real change in the gland.

Gonadotropic Substances in the Urine of Cancer Patients

The urine of certain cancer patients will cause ripening of the follicles in the ovary of immature rats and mice.^{108 281 etc.} Zondek attributes

this effect to a substance he calls prolan A. This occurs in 60 to 80 per cent of cancers of the female genital apparatus¹⁹³ 09 21 10 221 22, 231 etc. and almost constantly in cases of moles or chorioepitheliomas¹⁹³ 04 05 16 21 22 9 35 215 25 252 259 267 271, etc. In the latter there may be as many as 200 000 to 700 000 rat units per litre which is of great diagnostic value¹⁹³ 29 241 etc. In cases of testicular tumors, particularly in those of embryonic nature, enormous quantities of gonadotropic substances occur¹⁹³ 214 215 212 26 8 217 91 etc. which are described as prolan A but differ from this. The high content found in moles and tumors compared with the small amount in the pituitary, leads one to the conclusion that it originates in the tumors and not in the pituitary; this is also borne out by the differences in the action of prolan A and anterior pituitary extracts.

Carcinogenic Action of Pituitary Extracts

Hofbauer²²¹ insists repeatedly on the danger of anterior pituitary extracts since prolonged administration in guinea pigs produces hyperplasia of the endometrium and precancerous lesions of the uterine neck. Overholser and Allen²⁵¹ also found atypical epithelial proliferation and possible metaplasia, which seemed to be precancerous lesions; other investigators²⁰⁶ etc. do not admit that these are precancerous.

Action of Pituitary Extracts on Cancer

Posterior pituitary extracts (pituitrin etc.) have no influence on the growth of implanted tumors or human cancers²⁰² 219 227 67 71 272. With several anterior lobe extracts various results have been obtained depending on the injected substances, the type of tumor and the rapidity of its growth, in some cases an accelerating effect was observed,²⁰² 219 272 227 56 59 272, etc. in others there was no alteration. The inhibitory action on tumor growth by prolan A described by both Zondek and Hartoch²⁴² has received some confirmation⁰⁷ 211 24 250 61 etc. but other investigators have not observed this effect, or else obtained merely a nonspecific weakening in growth²²² 224 22 29 49 272 etc. The disturbing effect on tumor growth *in vitro* described by Reiss and Hochwald⁵⁶ Kriesch and Victorisz²¹⁰ has not been confirmed³⁴⁹.

GENERAL DISCUSSION

The existence of a direct antitoxic or anti-infectious action of the pituitary gland or its secretions has not been proved but the gland can modify the resistance of the animal by its metabolic action its regulating action on the thyroid or adrenal and on the vascular or nervous systems.

The gland can show certain histological changes during infections or intoxications, but

their functional significances are not understood. It has been thought that the increased growth in typhoid convalescents or sexual retardation and amenorrhea in adolescent tuberculous patients may be due to functional changes in the gland but as yet there is no proof of this.

Anesthetics and hypnotics are not tolerated well by hypophysectomized animals and after operation some species are more susceptible to infections, poisons of the nervous system (cobra venom, morphia, chloralose), blood pressure lowering agents (histamine, etc.) and blood sugar lowering agents (insulin, phlorhizin, etc.). Hypophysectomy because it produces hypothyroidism provokes a decrease in phagocytosis and accelerated formation of antitoxins (in dogs), the agglutinin production not being changed. The thyrotropic hormone of the anterior pituitary, by stimulating thyroid activity causes hypersensitiveness to anoxemia in rodents, in the mouse an increased resistance to acetone nitrile and in the dog a slightly increased resistance to chloralose occur.

The pituitary can be the site of benign or malignant new growths, also of metastases. The structure of the pituitary is modified in patients suffering from cancer. Hypophysectomy retards but does not prevent the growth of tumors and diminishes the number of implantations which take probably this is due to a metabolic action which should be studied. The urine of cancerous patients (especially cases of uterine tumors, moles testicular tumors) has a powerful gonadotropic activity. Pituitary extracts can accelerate the growth of certain tumors. In some cases prolan A has an inhibitory action but its specificity and its practical importance are doubtful.

FOODS CONTAINING ARSENIC AND LEAD

The Department of Agriculture has consistently maintained that foods containing added arsenic and lead in amounts held by qualified scientific opinion to be poisonous or deleterious constitute a definite menace to public health and, under the pure food law, are subject to action. As the result of intensive activities over a period of many years the Food and Drug Administration encounters today relatively few interstate consignments of fruits or fruit by products containing dangerous quantities of lead and arsenic.

The Washington Dehydrated Food Company was found guilty in 1933 in the Federal court in Yakima, Washington, of a violation of the Federal Food and Drugs Act in shipping in interstate commerce stocks of apple chops carrying residues of poisonous lead and arsenical sprays which might render them injurious to health. The firm later marketed apple chops containing lead and arsenic in amounts deemed by eminent toxicologists to be capable of injury to health. One of these shipments involved a consignment destined for export to France. The Government instituted seizure proceedings when lead and arsenic in such amounts were found, taking the position that the pure food law does not sanction the practice of making foreign countries a dumping ground for foods not measuring up to the criteria of fitness set for our own country. The lower Federal court in that instance, however, ruled against the Government, holding that the shipment fell within a proviso in the food law exempting, under certain conditions, violative shipments consigned to foreign shores. The court also expressed doubt as to the deleteriousness of the material.

An outgrowth of this adverse decision was the institution of a suit for damages by the president of the Washington Dehydrated Food Company against administrative officials of the Department of Agriculture who, in carrying out their duty, had reported the facts as to the arsenic and lead content of the export shipment. The civil suit for damages resulted in a hung jury and is of vital interest to every consumer since in its larger aspects it involved the

question as to whether a Federal officer, in the discharge of his official duties under the Food and Drugs Act, can be held personally liable for damages for reporting facts to his superiors in the event of an adverse court decision under the Food and Drugs Act. The action in St. Louis is the most recent chapter in the various legal actions which have grown out of shipments by the Washington Dehydrated Food Company—*Bulletin*, U. S. Department of Agriculture.

COOK PORK WELL TO PREVENT TRICHINOSIS

Reports received by the Department of Agriculture of several recent cases of illness and some deaths from trichinosis justify a repetition of the warning to cook pork thoroughly before serving. The parasites occur in a small percentage of hogs, which themselves suffer no apparent inconvenience. But the meat of such hogs, unless well cooked, constitutes a considerable danger to human health.

The assumption that pork which has passed inspection by a federal organization is safe even when eaten raw or undercooked is erroneous. There is no test that will show definitely whether trichinae are present in a sample of pork, except in some cases of severe infestation. Certain products that are customarily eaten without cooking in the home are given a special processing at federally inspected establishments, and are free from live trichinae. Pork products of the kind that ordinarily are cooked in the home are not processed in meat packing establishments, since thorough cooking is a complete safeguard.

When infested pork is eaten by human beings in a raw or insufficiently cooked state, the trichinae are set free in the digestive tract where they give rise to numerous young worms. The latter invade the muscles, thus causing the painful disease, trichinosis, which somewhat resembles typhoid fever, meningitis, and several other diseases that are characterized by fever. Severe cases of this disease are likely to result in death.—*Bulletin*, U. S. Department of Agriculture.

MENORRHAGIA OCCURRING AT THE ONSET OF CATAMENIA
IN A PATIENT WITH THROMBOPENIC PURPURA

Report of a Case

BY ARTHUR STERN, M.D.*

SINCE Werlhof in 1781 first described essential Thrombopenic Purpura, many syndromes, characterized by a diminution in the number of platelets, have been described and several classifications proposed. That most commonly accepted¹ consists of two main divisions:

1. Symptomatic Thrombopenic Purpura and
 2. "Essential" Thrombopenic Purpura.
- The latter so termed because no specific etiological factor can be found to explain the lack of platelets in the blood stream. Very briefly the characteristic findings in this second group (Werlhof's disease) are those of spontaneous hemorrhage into the skin and mucous membranes, a fall in the total count of platelets, prolonged bleeding time, normal clotting time, nonretractile clot and increased permeability of capillary walls.²

Many theories have been advanced to explain the thrombopenia and hemorrhagic tendency. As usual, their multiplicity bespeaks their inadequacy. Denny³ in 1887 first noted the thrombopenia and suggested it as the main factor in the causation of the hemorrhages, but other investigators⁴ have reported several cases in which the other cardinal symptoms were present including hemorrhage but in which the platelet counts were normal or only slightly reduced. They were of the opinion that increased permeability of capillary vessels is the essential feature. Others have proposed theories of "splenic toxicity" with inhibition of megakaryocytes in the bone marrow, qualitative changes in the platelets and increased phagocytosis of platelets by the cells of the reticulo-endothelial system.^{5, 6, 7}

One of the phenomena noted in essential thrombopenia is excessive menstruation usually in the form of menorrhagia often associated with severe and sometimes fatal consequences. A cursory review of the literature discloses many cases of this type reported in the foreign literature but relatively few in this country. Menstrual abnormalities are usually investigated from an endocrinological or gynecological viewpoint. It is probably true that few clinicians think of blood dyscrasias as an etiological factor in their production. The rapid almost fulminating course and the effective although non-specific treatment available for these patients, make it important that they be recognized fairly early.

REPORT OF CASE

First admission December 1 1930

N. M., a white Italian child was eight years old when first admitted to the Worcester City Hospital. She was a full term normally delivered baby with an uneventful infancy except for whooping cough at one month of age. Her tonsils and adenoids were removed at four years of age without bleeding. There was no history of purpura, hemophilia or any other familial disease. About one year before entry many small black and blue marks had appeared on both legs. Since then she had never been free from at least one ecchymotic area on her body. About one month before entry she ran into a playmate. Ecchymosis of her face and severe nosebleed followed this episode. After that she suffered from recurrent epistaxis. There was also bleeding from her gums when brushing her teeth. Physical examination showed a well-developed and nourished child. There were ecchymotic areas over her right shoulder and both lower extremities. The liver and spleen were not palpable. Laboratory data: R.B.C. 4,070,000, W.B.C. 11,800, Hgb. (Dare) 60 per cent. A smear showed great paucity of platelets and a count gave 16,000. Bleeding time was twelve minutes and clotting time eleven minutes. The clot retracted in three hours (venipuncture). Serum calcium was 9.1 mg. and phosphorus 4.4 mg. Calcium lactate and iron ammonium citrate were given as symptomatic treatment and the patient was discharged on the twelfth day. Platelet count on discharge was 46,000.

Second Admission May 18 1932

She had been well until the day of entry when she developed severe epistaxis staining fifteen diapers. Because of the uncontrollable hemorrhage she was brought to the hospital. Examination at this time showed moderate pallor. There were ecchymotic areas ranging from pinpoint size to that of a silver dollar on the arms, legs and chest. R.B.C. 3,940,000, W.B.C. 16,400, Hgb. 60 per cent. (Tallqvist). Platelets 68,200. She was transfused twice followed by cessation of the epistaxis. Attempts to find a bleeding point on the nasal mucous membranes were unsuccessful. Discharged on the nineteenth day.

Third Admission December 5 1932

She had had a tooth extracted the previous day and there was subsequent hemorrhage of alarming proportions for which hospitalization was sought. Physical examination was unproductive of positive findings except for slight pallor and an oozing tooth socket which stopped bleeding promptly upon application of a pack. Bleeding time six minutes, clotting time four and a half minutes. No other laboratory work done. Discharged in three days.

Fourth Admission August 6 1935

The patient had been symptom free until three weeks before admission when she came down with a "cold." Two weeks before entry she had begun to bleed from the gums and this had continued up to the time of admission. Examination at this time showed only the signs of an upper respiratory infection and also several hemorrhagic spots on the buccal mucous membrane. There was also oozing at the gingival margins. R.B.C. 4,560,000, W.B.C. 6,600, Hgb. 75 per cent. (Tallqvist). Platelets 70,000.

*Hern. Arthur—Intern, Worcester City Hospital. For record and address of author see "This Week's Issue" page 1157.

Bleeding time ten minutes, clotting time three and a half minutes. The patient was treated symptomatically for her upper respiratory condition and was discharged on the third day.

Fifth Admission November 26, 1935. She is now thirteen years of age.

Since discharge five months previously, she had not been well, complaining of continual weakness. Her catamenia began eight days before entry, for the first time, and continued until her admission into the hospital, with the passage of large clots daily. For the past month she had had daily attacks of epistaxis each morning upon arising. Examination disclosed a blanched, sallow appearance of her face and mucous membranes. There were several ecchymotic areas below the knees bilaterally. The blood pressure was 110/60. She was observed closely for nine days, during which time she had several attacks of profuse hemorrhage from the vagina with the passage of large blood clots, followed by intervals of only slight bleeding. On the ninth day she received 300 cc of citrated blood and subsequently was transfused three times. In the meantime she was put on supportive treatment of calcium

of favorable reports. Some mention of irradiation over the spleen has been made recently but no conclusions as to its effectiveness have been made. In the present case, bleeding ceased after the second exposure to x-rays, but there had been two transfusions previously so that results are inconclusive. Payne⁸ maintains that splenectomy should be done as early as possible to forestall the appearance of aplastic changes in the bone marrow and offers an index of operability in the white blood count and number of reticulocytes, if these are normal or elevated, he states, the chances of cure from splenectomy are good, if depressed, splenectomy is contra-indicated. Transfusions, of course, are indicated preoperatively, as often as necessary until the patient's optimum condition is reached and are sometimes effective in lessening or even stopping the menorrhagia.

(CHART 1)

LABORATORY DATA ON FIFTH ADMISSION

Date	R B C	W B C	Hgb	Platelets	Bleeding Time	Clotting Time	Reticulocytes
11-26	4,250,000	8,400	70 (T)	114,000	2 min	5 min	15%

* S = Sahli

gluconate, one dram tid, ferrous sulphate, grains 3 tid, cod liver oil, drams one tid, also a high vitamin and high caloric diet. On the twelfth day she was given radiation over the spleen (200r) and received the same dose every second day for two more treatments. Her blood picture was followed closely (chart 1). On the eighteenth day her vaginal bleeding ceased and on the twenty-fourth day a splenectomy was performed under ether anesthesia. Convalescence was uneventful and there was no further bleeding. She was discharged on the forty-fourth day, under the care of her family physician.

COMMENT

Essential thrombopenic purpura is rarely a surgical emergency. Only in the presence of intractable hemorrhage as from the nose or uterus does the problem of treatment become acute. While there is wide disagreement at present on the proper treatment of this disease, most authorities agree that in the early mild forms, supportive measures, including calcium in some form, concentrated vitamins, rest and large doses of iron, deserve an adequate trial. In the acute fulminating cases where the patient is in danger of exsanguination, the problem is different; something must be done quickly. During the past years the operation of splenectomy has attained prominence with a preponderance

SUMMARY AND CONCLUSIONS

1. A case of menorrhagia with the first menstrual period is reported in a girl thirteen years of age, who had been known to have essential thrombopenic purpura for the past five years.
2. Treatment consisted of a preoperative course of calcium, iron and vitamins with frequent transfusions and a mild course of irradiation over the spleen, followed by splenectomy.
3. Splenectomy is the treatment of choice in chronic cases, providing the Payne index of operability is satisfactory.
4. Irradiation of the spleen deserves further investigation as a palliative or curative measure.

CASE 22231

PRESENTATION OF CASE

A sixty-seven year old unmarried white woman was admitted complaining of blurring of vision and drowsiness.

The patient was perfectly well until about six months before entry at which time she began to have blurring of vision and occasional spells. The latter would manifest themselves by causing her to drop off into brief nap at odd intervals occasionally while conversing with another person. At about the same time she began to stagger occasionally while walking. She had one severe headache lasting for about half a day at the onset of her illness but there were none thereafter. After about two months she began to take "potash" as medication but this caused her mouth to dry up and she discontinued it after a month. She was unable to taste anything for several months afterward however. At the onset of her illness the patient had gradual swelling of her entire face and neck and the left side of her face seemed to lurch at times. This apparently gradually subsided for it was not discernible at the time of her admission. About three weeks before coming to the hospital she withdrew considerable money from the bank took a taxi from an outlying town into Boston and made several unusual purchases spending in all about \$800. Her actions were surprising and unaccountable to her family but no further details were noted. Her mental state was placid and she evidently noted no abnormality.

Physical examination showed a well-developed and nourished female in no discomfort. The pupils were equal but irregular. They reacted sluggishly to light. The right fundus was obscured by media opacity, but the left was normal. Peripheral vessels were thickened and tortuous. The lungs were normal except for a slight diminution in intensity of breath sounds in the right axilla. The heart was negative. The blood pressure was 130/70. The abdomen was distended and tympanitic. There was slight tenderness in the right upper quadrant but the findings were otherwise normal. Reflexes were symmetrically equal.

The temperature was 99°, the pulse 95. The respirations were 30.

Examination of the urine was negative. The blood showed a red cell count of 3,850,000, with a hemoglobin of 75 per cent. The white cell count was 12,200. 84 per cent polymorphonuclears. Reticuloocytes numbered 35 per cent and the red blood cells had a volume slightly greater than normal. The nonprotein nitrogen of the blood was 28 milligrams. A Hinton test was negative. A lumbar puncture done with some difficulty showed blood tinged fluid. The initial pressure was 150 and the dynamics were normal. A count showed 1,452 cells of which 1,442 were red blood cells, 2 monocytes and 8 lymphocytes. The ammonium sulphate ring test was positive and the total protein was 47 milligrams. The spinal fluid sugar was 76 milligrams and the Wassermann test was negative. A basal metabolic rate was +17 per cent. An electrocardiogram showed a low T₁ and slight inversion of T₂ and T₄. The serum protein was 4.5 grams. Examinations of the stools were negative.

Following her entry the patient became perfectly rational and offered no complaint at all. Her temperature fluctuated between 99° and 100° and the pulse rose to 100. Examination on the third day showed dullness over the right lower lung area and a friction rub and rales were audible.

An x-ray examination of the chest showed hazy rather homogeneous dullness at both bases which obliterated the costophrenic angles and faded out rapidly above. There was a triangular area of dullness at the posterior aspect of the right side of the chest which had the general size and shape of a collapsed lower lobe. The heart and mediastinum were displaced toward the right with inspiration and slightly toward the left with expiration. The heart shadow was partially obscured but appeared slightly enlarged in all diameters. The aorta was tortuous and there were no mediastinal masses. A skull plate was negative.

A needle was inserted into the right lower chest and a small amount of bloody fluid was removed. Culture of this material showed gram positive filamentous branching organisms. Histologic examination showed only acute inflammatory exudate. About this time she developed edema of both the upper and lower extremities which increased progressively. There was no respiratory difficulty; the patient was perfectly calm, and her appetite was unimpaired. At the end of the second week she developed a month condition which was termed thrush. During the succeeding week she developed a gradually progressive dyspnea; the white cell count rose to 27,000 and the temperature to 102°. She died on the twenty-third hospital day.

NOTES ON THE HISTORY

DR FREDERICK T LORD This patient evidently had no mental symptoms following her entry to the hospital. She had some elevation of temperature, 99° to 100° , and a pulse to 100.

Putting these physical signs together, she has diminished breathing, dullness and friction rub, but nothing is said about bronchial breathing, egophony or whisper.

X-ray of the chest was done. We might see the films at this point.

X-RAY INTERPRETATION

DR GEORGE W HOLMES The skull was examined and I think was essentially negative for a person of her age. She has some thickening here but that is not important. We would interpret these films as normal. The pineal gland is in the usual position.

We have a series of films of the chest. As described in the note, the right lung field was distinctly smaller than the left. The diaphragm was high and partially obscured by fluid. The costophrenic angle is not visible but it looks as if there might be a small amount of fluid there. In this area there is a shadow of increased density which might represent a partially collapsed lobe. The heart shadow is enlarged. The aorta is normal. The lateral view does not give much added information. These were small films with an attempt to show the detail of the structure around the lung. I cannot get any information from them.

I think we would have to say that the x-ray of the skull was negative, that the chest showed a small amount of fluid in both bases, elevation of the right diaphragm with incomplete expansion of the right lung, and a mass near the root of the lung which might be partially collapsed lung. I think we have pretty good evidence of bronchial obstruction. The air is not getting into that lung.

FURTHER NOTES ON THE HISTORY

DR LORD The history is meager in the omission of a statement regarding such respiratory symptoms as cough, dyspnea, pain and wheezing. In view of the anemia, it is desirable to know if there was numbness of the extremities and a smooth tongue.

As the patient was rational without complaints after admission and the neurologic examination without significant findings, I am inclined to regard the cerebral symptoms as of functional rather than of organic origin, but it would be desirable to know the field of vision, sensation and ataxia, including Romberg.

Regarding the laboratory findings, primary anemia is suggested by the large red cells and approximately normal color index, and makes it desirable to know if the red cells were oval the

platelets diminished and the results of a gas tric analysis. The high reticulocyte count may be due to regeneration of blood spontaneously or after the administration of liver. The ratio of white to red cells in the systemic blood is about one to three hundred and, in consequence, in the spinal fluid about five white cells are to be expected from admixture with blood. As there were only about ten in all in the spinal fluid the cell count is probably without significance. The positive globulin test, the slightly elevated total protein and the sugar may be disregarded under the circumstances and, on the whole, the spinal fluid may be regarded as negative.

The electrocardiogram is abnormal with low T_1 and inverted T_2 and T_4 . Inversion of T_3 is not significant, but the low T_1 and inverted T_2 and T_4 may be said to be of somewhat ill omen. The elevated basal metabolic rate probably has no special import under the circumstances.

We come to the most significant of the laboratory findings, i.e., the presence in the bloody fluid obtained from the chest of nothing histologically but an acute inflammatory exudate and by culture and smear a gram-positive, branching, filamentous organism. For the identification of this organism, such further data are necessary as a description of the culture, information regarding growth with or without access of air and at room or incubator temperature and whether the gram-positive organisms are acid- or alcohol-fast.

DIFFERENTIAL DIAGNOSIS

With the data at hand, I am inclined to say that the patient has arteriosclerosis, a lenticular cataract and an anemia with some features suggesting pernicious anemia. The physical and x-ray findings suggest a plugged right lower lobe bronchus. This naturally raises the question of malignant disease among other causes of bronchostenosis, and a complicating inflammatory process in the lung supplied by the occluded bronchus. The neurologic disturbance early in the course of the disease raises the question of possible metastatic cerebral malignancy or metastatic cerebral inflammation.

With respect to the nature of the inflammatory process in the chest, we must consider the possibility of an infection with the group of organisms which show branching filaments in culture. In this connection I am handicapped by the limitation of available data to the morphology and staining reaction of the organism in culture.

There is a group of organisms which are found in tissue and exudate as round or oval cells. One of these, the cryptococcus, can at once be excluded because of multiplication in culture by budding without the formation of

mycelium Sporotrichosis is usually confined to the skin and subcutaneous tissues. The sporothrix is rarely demonstrable in the tissues or exudate as oval bodies but is usually first found in cultures which show a gram staining branching mycelium and spores. The absence of any mention of spores here and the pulmonary site of the disturbance are against sporotrichosis. The growth in cultures of the blastomycetes and coccidioides immitis is yeast like with the formation of branching, mycelial elements. As no conidia or segmentation is mentioned these organisms can with probability also be excluded.

The type of organism here falls, with probability, into one of two groups, the actinomycetes or the streptothrix. I may say with respect to these organisms that there is an unfortunate confusion in terminology. The term actinomycetes boydii (Harz) should in my opinion be restricted to anaerobic organisms of the Wolff Israel type. These organisms the cause of both human and bovine infection in tissues form compact colonies composed of branching gram staining, filamentous organisms with radially disposed club bearing filaments and grow in cultures under essentially anaerobic conditions at incubator and not at room temperature.

There is another and quite different group of organisms found in fresh material as isolated, branching, gram staining filaments or a loose aggregation of interlacing filaments, without true club formation but at times club-shaped swelling of the terminal portion of the filaments and growth in culture under aerobic conditions at room or incubator temperature. The terminology for this group is confusing. In accordance with the principles of nomenclature "nocardia" is tenable, but common usage appears to make the term "streptothrix" acceptable.

There is a tendency to include all branching, filamentous organisms forming colonies with radiating filaments and clubbed terminal portions under the term actinomycetes and to use such designations as "actinomycetes", "streptothrix" and certain others as synonyms. This is unfortunate as the two organisms are widely separated in biologic peculiarities and give rise to diseases which are quite different in their mode of origin and in their clinical picture.

It is obvious, with the data at hand that a distinction between these two organisms can not be made and I may say that the infection falls into the group of either actinomycosis or streptothricosis.

There is one other matter which merits some attention and that is the development under observation of a disturbance in the mouth termed thrush. Thrush is not an uncommon complication of severe illnesses and I am not inclined to relate the mouth and lung disturbance in any way.

CLINICAL DISCUSSION

DR. HENRY R. VIETS. I know the answer to the problem so I will not say more than just a word about the onset of this rather remarkable illness. This patient was one of four maid en sisters living very quietly in a town fifty miles away and none of them had ever had any signs of mental disease. Their family physician was a well known practitioner who had known the family for a long time and, although there is a little indication that something happened to this patient before this episode three weeks preceding entry to the hospital, except for the swelling of the face, it seems probable that the other symptoms were not well substantiated. This patient suddenly one morning went to the local bank, drew out some money, went fifty miles to Boston in a taxi, made unusual purchases, such as a barrel of sugar bought two fur coats for her sisters, and came back at eleven o'clock at night, having spent well over eight hundred dollars. For a quiet, retiring maiden lady who had never done anything but attend church affairs and things around the town, this was an extraordinary procedure and made us think we were dealing with an acute psychosis. I saw her on that account a few days later. When she was seen neurologic examination was entirely negative and general examination was also negative as far as I could make out. She had had no respiratory symptoms previously and nothing to call attention to a lung disease. She was mildly confused, did not know her doctors and was not quite sure what hospital she was in. She had various plans about taking her sisters on extensive trips and so forth and she said she had the money and wanted to do something for the family. There was a vague state of euphoria that went along with the confusion. Then she was transferred here to the Baker Memorial and the rest of the story you have heard. While she was here she was still more or less confused and was not quite sure where she was. She still had ideas about buying expensive presents, taking trips and so forth. She was co-operative and remained in bed. A few days later signs in the chest were discovered and a tap done.

DR. FRANK T. HUNTER. I think I can answer a few of Dr. Lord's questions. As to the one about the physical examination of the lungs I saw her on the second day and my findings were definitely those of fluid at the right base possibly some at the left, with diminished voice and breath sounds and dullness to flatness.

In regard to the blood picture the cell volume was only slightly elevated by the hematocrit method and it brought up the question whether she had pernicious anemia on top of something else. The reticulocytes were 35 be-

foie liver was given. She was given liver with the idea that if she did have pernicious anemia we had better lose no time in starting treatment. No gastric analyses were made.

As to the chest tap, I did it myself and could obtain nothing until I put a lumbar puncture needle in for a depth of three inches. I then got a small amount of gelatinous bloody material, possibly not over two or three cubic centimeters, and then withdrew. I was rather surprised that in view of the x-ray picture and physical findings I did not get a considerable amount of clear fluid.

About her appetite, not only was it unimpaired but she sent out for and ate a large dish of "hot dogs" and potato salad. There is no question about her appetite being good.

The mouth condition, termed thrush, on direct smear showed a very curious large gram-positive bacillus. It cleared up in thirty-eight hours. Clinically the picture could not be distinguished from the type of thrush one sees in infants. As for the filamentous branching organisms, they were present in large numbers in direct smear from the puncture.

DR HOWARD B. SPRAGUE: I saw this patient once in consultation, before much of the laboratory data had been returned, in reference to whether there was a cardiac factor. The thing that impressed me was that the congestion of both upper and lower parts of the body suggested more an obstructive affair than a primary cardiac failure. I thought the most likely thing was either malignancy or an inflammatory process of the right base with probably a metastatic process in the brain.

The electrocardiogram does suggest some decreased myocardial function. I would like to correct one statement about the electrocardiograms, that is, in relation to the T wave in lead four, which is normally inverted in the technique that we use in this laboratory and is commonly used now in this country.

CLINICAL DIAGNOSIS

Carcinoma of the bronchus

DR FREDERICK T. LORD'S DIAGNOSES

Arteriosclerosis

Pneumonitis, actinomycosis or streptothricosis

Pernicious anemia?

Malignant bronchiogenic carcinoma?

ANATOMIC DIAGNOSES

Adenoma of the bronchus

Multiple abscesses of the lung, right lower lobe

Pulmonary streptothricosis

Pulmonary atelectasis, right upper and middle lobes

Empyema

Arteriosclerosis, coronary and aortic
Hypertrophy of the heart
Secondary anemia

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY: The autopsy, unfortunately, was not a complete one. We can not tell you whether she had anything in the brain. The findings in the chest were as interesting, however, and quite as unexpected as everything else in the clinical course. There was a small empyema. We found that the right lower lobe of the lung was tremendously enlarged, almost completely filling the pleural cavity, and was filled with large multilocular abscesses. On cutting down the bronchus we found just at the bifurcation of the lower lobe bronchus a polypoid tumor which microscopically was perfectly characteristic of a so-called benign adenoma of the bronchus. We have had eight of these benign adenomas preceding this case, all of them heretofore in young patients. The age group in our cases and for the most part in the literature has been a very standard one, running from the late teens to the late twenties, whereas this woman was in the sixties. The question always comes up as to whether they should be considered benign or malignant. The major part of this tumor looks like the typical benign adenomas in young people. It is not encapsulated, however, and the base infiltrates the bronchial wall pretty deeply. Cases of this sort have been described for a good many years as slowly growing carcinomas of the lung, and I would not be surprised at anyone's making that diagnosis on section of this case. On the other hand a very careful search by four members of the department failed to show a single mitotic figure. One wonders if there is any possibility that the tumor may have been present since youth. It seems almost incredible that it could be present all that time without producing symptoms.

The other findings were not of any particular significance. The heart was hypertrophied. There was a moderate degree of coronary sclerosis. The bone marrow was hyperplastic but showed no increase in megaloblasts. Considering the short time she was on liver therapy that allows us to rule out pernicious anemia. The bronchus beyond the tumor was moderately dilated, not markedly so. On microscopic examination of the lungs we have not been able to find any other branching organisms. Very few organisms are visible in the sections. The only ones I have been able to find are evidently cocci, so we must assume that the pulmonary infection was a mixed one.

A PHYSICIAN: Do you know anything more about the cultures?

DR LOUIS DIENES: The gram-positive fila-

mentous and branching organism which was visible in the pus grew readily on all media. It is an aerobic organism belonging to the group usually called streptothrix. This strain differs in many respects from the actinomyces responsible for most cases of human actinomycosis strains which as Dr. Lord pointed out, form a well-characterized group. Organisms more or less similar to actinomyces are widely distributed in nature as saprophytes and for all these organisms at present the name actinomyces is used as a generic term. The various strains belonging to the group are regarded as different species of the same genus.

DR. SPRAGUE: Did you find a satisfactory mechanical explanation for venous obstruction in the chest?

DR. MALLORY: No. The increased venous pressure presumably must have been due to some degree of heart failure.

A PHYSICIAN: Was the lower lobe as large as a normal inflated lobe?

DR. MALLORY: Larger. I should say the other lobe was collapsed and displaced.

A PHYSICIAN: Were the so-called actinomyces artefacts?

DR. MALLORY: I do not believe so. I myself, saw the smear of the lung puncture and there were unquestionably filamentous organisms in the material. They grew out readily moreover, in culture.

CASE 22312

PRESENTATION OF CASE

First Admission. A nineteen year old American office boy was admitted complaining of cough and hemoptysis.

Two years before entry after a vague illness of a week's duration during which he felt slightly feverish and lost his appetite he suddenly had a paroxysm of coughing associated with a small amount of whitish sputum. A few minutes later he coughed up some bright red blood and returned to his home at once to go to bed. He remained in bed for three days suffering from occasional coughing spells after which he expectorated dark clots and bright red blood. During the three days he brought up about a pint of blood in all. He was told by a physician that he had pneumonia and was sent to a hospital where he remained for three weeks. Sputum and blood examinations and a chest tap were noted as noncontributory. There was occasional blood streaked sputum during his hospital stay but he had improved markedly at the time of his discharge. There were occasional night sweats and chilly sensations but no further hemoptysis. Eight months after this illness he was confined to bed with "influenza" associated with a cough productive of mucoid, occasionally blood streaked material. There-

after he returned to work and except for two occasions, during which he took cold and had some blood streaked sputum, he remained comparatively well until two months before entry. At this time he developed a sore throat and a cough which was productive of a moderate amount of occasionally blood-streaked yellowish sputum. After ten days he began to expectorate as much as a teaspoonful of bright red blood three or four times daily. He went to bed and remained there until his admission. He had occasional fever sometimes up to 102°. His appetite flagged but he felt only slightly run down. More recently he controlled his cough voluntarily and the hemoptysis occurred only about once a week, although now it amounted to about a tablespoonful.

Physical examination showed a well-developed but slightly undernourished young man who did not appear acutely ill. The throat was slightly injected and there were several patches of readily removed yellowish exudate. The heart was neither enlarged nor obviously displaced. A soft early systolic murmur was heard at the base. The blood pressure was 140/80. The lungs showed slight impairment of resonance on the left infraclavicular region and diminution of resonance, breath sounds, and tactile fremitus in the postero-inferior portion of the right chest.

The temperature, pulse, and respirations were normal.

Examination of the urine was negative. The blood showed a red cell count of 5,150,000 with a hemoglobin of 75 per cent. The white cell count was 10,400. 91 per cent polymorphonuclears. A sputum specimen was negative for tubercle bacilli and spirochetes. A stool examination was negative. A Hinton test was negative.

X-ray examination showed mottled dullness along the course of the lung markings extending to the right base. In the lateral view the mottling lay in the posterior portion of the lower lobe. After lipiodol injection the left lower bronchial tree was negative. On the right there was obstruction to the passage of the opaque medium down the right lower main bronchus at a point just below the bifurcation of the middle bronchus. At the point of arrest the lower border of the lipiodol had the appearance of a cap formation.

The patient remained quite comfortable during his hospital stay. On the eighth day a bronchoscopy was done. This showed a rounded red smooth, shiny mass obstructing the right main bronchus about one quarter of an inch below the lower lip of the upper lobe bronchus. The mass was firm but bled readily at contact with the bronchoscope. No reaction in the surrounding bronchial mucosa was noted. A biopsy showed no definite tumor. Two bron-

choscopies were done at succeeding weekly intervals. Further note was to the effect that the tumor mass was not movable and was quite close to the bifurcation of the right main bronchus. Thereafter the patient received several x-ray treatments to the right chest. He remained quite comfortable and only occasionally had blood-streaked sputum. He was discharged on the forty-sixth day.

Final Admission, two months later

Following his discharge the patient remained comfortable. A month before re-entry another bronchoscopy showed the tumor to be slightly more hemorrhagic than previously. It now filled almost the entire bronchial lumen. He returned to the hospital for further treatment having had only a single blood-streaked sputum in the interval.

Physical examination was similar to that of the previous admission. A few inspiratory squeaks were heard in the right lower chest posteriorly and the breath sounds were slightly diminished in this region.

The temperature, pulse, and respirations were normal.

Examinations of the blood and urine were negative. Several sputum examinations were negative for blood and tubercle bacilli.

The patient remained comfortable while in the hospital. On the eleventh hospital day an exploratory thoracotomy was done.

DIFFERENTIAL DIAGNOSIS

DR JAMES H. TOWNSEND. In this case we have hemoptysis coming not out of a clear sky but after a short vague illness of one week's duration, presumably a slight respiratory infection which started him coughing. Then he had hemoptysis. At the age of nineteen certainly in more than ninety per cent of such cases the cause will be found to be tuberculosis. The other small percentage, and presumably in this case we are dealing with that percentage, will be found to belong in another group of rarer conditions which Dr. Lord has just discussed. Among them are tumor (although this is very young for a tumor to cause hemoptysis), rare lung infections such as actinomycosis, a queer sort of pneumonia or possibly the beginning of bronchiectasis or lung abscess. One must also consider the possibility of an unrecognized foreign body. He had a severe coughing fit at the onset of this, but nothing is said about having swallowed anything the wrong way.

I suppose the sputum was negative for tuberculosis, which is to be expected at this stage if it were tuberculosis, and I take it he did have some signs in his chest, presumably the lower part, and they did a chest tap which was negative. What these signs may have been we are not told. At this time we get a suggestion of

pus in the sputum which had not been present before.

We are dealing with a situation characterized by a number of brief acute infections, during each one of which cough was a prominent feature and on each occasion there was some blood spitting. On some occasions it was just tiny amounts, but at the first illness there was as much as a pint. At the present illness he is raising considerable quantities of blood, and seems to have more septic involvement. He is now running a temperature and has pus in the sputum as well as blood.

"The throat was slightly injected and there were several patches of readily removed yellowish exudate." I take that to mean that he did have an acute upper respiratory infection. We are not told just where that exudate was, whether on the tonsils or the pharyngeal wall or on the palate. The presence of these patches suggests some unusual sort of throat infection, such as thrush which possibly might get down into the lungs, but on the whole I am not inclined to take these yellowish patches very seriously.

"The lungs showed slight impairment of resonance in the left infraclavicular region and diminution of resonance, breath sounds, and tactile fremitus in the postero-inferior portion of the right chest." In other words some signs reported on both sides of the chest. On the left side the only thing mentioned is slight impairment of resonance in front in the infraclavicular region. I take it that the examiner was looking for evidence of apical pathology. Nothing else was present on that side. I doubt if it has any significance. In the right posterior lower chest there are signs of diminished resonance, diminished breathing, and diminished tactile fremitus. Those are signs suggesting either bronchial obstruction or possibly a small amount of fluid.

We have no mention in this history of pain in his chest and no mention that his cough is related to position.

He had not lost enough blood to make any real difference in his blood picture. The total white count suggests that there was not much infection but there is a very high percentage of polymorphonuclears. He does not seem sick enough though to have the total white count rather low because of an overwhelming infection.

This is all two years after the onset of hemoptysis, and I should think that at this time several negative sputa for tuberculosis are certainly significant and go a long way in ruling out tuberculosis as a cause of his present condition.

The pathology all seems to be in the right lower lobe and the dullness in the left upper lobe apparently was of no significance. Would

you like to comment on the x rays Dr Hampton?

X RAY INTERPRETATION

DR. AUBREY O. HAMPTON This triangular area of dullness occupying the posterior inferior aspect of the right side of the chest is quite typical of a collapse of the lower lobe and the films taken after lipiodol demonstrate quite clearly the point of obstruction in the right lower lobe bronchus. The inferior margin of the lipiodol shadow shows a concave defect which is often called "cap formation" and is characteristic of a rounded intrinsic mass within the bronchus. There are no other significant findings.

DIFFERENTIAL DIAGNOSIS CONTINUED

DR. TOWNSEND We have definite evidence that there is obstruction in the right lower main bronchus within an inch or so of the point where the middle bronchus branches from it and the question is what is the nature of the obstruction? The mottling extended into the left base below. This evidently is what one would expect in the way of infection below such an obstruction, doubtless atelectasis and beginning bronchiectasis or abscess formation.

The key to this situation seems to be the bronchoscopic examination. I think this illustrates the importance of making bronchoscopic examinations in all unusual cases of hemoptysis. If this had been done two years previously, possibly the outcome might have been different. There is definite pathology in the right lower bronchus which is described as a tumor mass with very little reaction about it, a mass which bleeds readily, but when they took a specimen from it it showed no definite tumor. I think we can be pretty sure that is not a foreign body. If a foreign body had been there there would have been much more reaction about it and much more pathology in the lung below it. Moreover the bronchoscopist visualized the mass and it bled. It presumably is living tissue and the question is the nature of it.

This boy is only nineteen years old. He was seventeen years old at the onset of his illness. He is two years younger than any of the cases of carcinoma of the lung reported by Arkin and Wagner in the *Journal of the American Medical Association* February 22, 1936. They reported 125 cases, the youngest twenty-one, only three under thirty. This boy was seventeen. Moreover, if it had been malignant to begin with one can hardly conceive that it would not have extended farther or metastasized in the intervening two years. Possibly it may have begun as a benign adenoma and more recently become malignant. There are a number of different tumors that may arise in this region, some may arise directly in the

large bronchus and some outside it and extend into it. In this case by x ray we have no visible evidence of tumor mass outside of the bronchus. This presumably does arise inside and from the bronchial tube itself. Benign adenomata as well as sarcomas occur in this neighborhood, and there is the very rare hemangiosarcoma. The fact that this bleeds so readily suggests that it might belong to that blood vessel tumor type.

Is there any evidence that this might be a metastatic process which has extended into the bronchus? There is none by x ray. We are not told much about the rest of the physical examination but presumably there was no evidence of any tumor anywhere else in this man's body.

We have three bronchoscopies. I take it that at least one of these they probably tried to remove this mass but were unable to do so and I would read between the lines that they gave x ray treatment hoping it might shrink the thing and then after an interval hoped that they might do more. In any case he was out for two months and then came in for his final admission.

"A month before entry another bronchoscopy showed the tumor to be slightly more hemorrhagic than previously." Again a suggestion of very vascular sort of tumor.

It now filled almost the entire bronchial lumen. Evidently it did not respond to x ray therapy.

"A few inspiratory squeaks were heard in the right lower chest posteriorly and the breath sounds were slightly diminished in this region." Apparently he still does get considerable air into the right chest.

"Several sputum examinations were negative for blood and tubercle bacilli." Again being sure to rule out tuberculosis. There is no evidence of it.

We have evidence of a definite tumor mass in the right main lower bronchus which has been present for two years at least. We have no evidence of metastases and no definite evidence of a tumor mass in the lung tissue itself from which this arose. On the whole I think it is most likely that this tumor at least started as a benign adenoma or a hemangioma in the bronchial tube, although by this time there may have been malignant changes that developed in the base of it.

He had a thoracotomy presumably because they were unable to remove the lesion by bronchoscopy and they hoped that by a direct approach or approach through the chest wall they might be able to remove it. Dr. Churchill can tell us about that.

DR. DONALD KING I saw this boy before he was admitted to the hospital. My diagnosis was bronchiectasis because we are getting used to seeing the hemorrhagic form of this disease.

Besides hemorrhage this patient also had a story of repeated bronchial infection. After his admission to the hospital the first diagnostic procedure was lipiodol injection. This showed complete obstruction of the right lower lobe bronchus, so that the next step was bronchoscopy and the specimen obtained through the bronchoscope for biopsy showed a benign adenoma which was obstructing the bronchus and had therefore caused bronchiectasis in the obstructed lobe.

We have had altogether eight cases of this so-called benign adenoma of the bronchus. Five of these are living and three have died. Of the three who have died one was given x-ray treatment and had radium seeds implanted in the growth. At autopsy the tumor was still present and the entire lung was destroyed by a suppurative process. The second fatal case died in another hospital after an attempt at bronchoscopic removal of the tumor. The death was said to have been due to novocaine poisoning. The third fatal case is the one presented here today. Of the five living cases one was treated with radium seeds and has done very well, and four have been operated upon. Three of these operative cases have done very well and one is much improved.

The only other point that I wish to make is that repeated bronchoscopic biopsies are often necessary. In one case six bronchoscopic specimens were reported by the pathologists to show only chronic inflammation, and it was not until the seventh specimen was taken that a report of tumor was made.

CLINICAL DIAGNOSES

Carcinoma of the lung
Pericarditis

DR JAMES H. TOWNSEND'S DIAGNOSES

Adenoma of the right primary bronchus, possibly with malignant changes

ANATOMIC DIAGNOSES

(Adenoma of the bronchus)
Operative wound. Thoracotomy and lobectomy of the right middle and lower lobes.
Pneumothorax, right.
Pleuritis, acute fibrinous, right.
Pericarditis, acute fibrinopurulent.
Acute myocardial degeneration, subpericardial zone.
Myocarditis, fibrous, focal.
Bronchopneumonia, left lower lobe.

PATHOLOGIC DISCUSSION

DR EDWARD D. CHURCHILL. The treatment of these cases is an interesting problem. It seems very drastic to attempt a pneumonectomy

or lobectomy for a so-called "benign" tumor. By "benign" I mean a tumor which is not given to metastasis or killing by direct extension. These tumors are not benign in the real sense of the word because they eventually do kill the patient. They kill by obstructing the bronchus. Some advanced cases show complete bronchial obstruction, fibrosis and bronchiectasis of the lung leading to a fatal termination. So it is histologically benign, clinically fatal.

The cause of death here, as in the other case, is infection. The inferior pulmonary vein is less than a centimeter in length and in ligating and freeing it a small opening was made into the pericardium. This was sutured but apparently contamination from the bronchial stump was sufficient to produce suppurative pericarditis. He was treated by aspiration and drainage.

This picture is the resected lower and middle lobes. Here is the bronchus and here the polypoid mass in the bronchus. A part of the tumor lies in the lumen of the bronchus and a very considerable proportion lies outside of it. In the majority of these cases the tumor has been confined to the bronchial wall or to the lumen of the bronchus but in this case the tumor had grown beyond the cartilage of the bronchial wall and spread outward a distinct distance into the mediastinum. That is a point of considerable importance from the point of view of therapy. If these tumors could be counted upon to remain entirely within the bronchial lumina they might be treated by bronchoscopic methods with success. Even if one did not succeed in entirely removing the tumor it would be possible from time to time to take off new excrescences as they arose.

DR TRACY B. MALLORY. This is the first case of so-called adenoma of the bronchus which we have presented at one of these conferences. Although we have now seen nine of them in our own clinic and have also had a chance to review several similar cases from other clinics, the recognition of these tumors as a distinct pathologic entity is a relatively recent event and credit for it is due primarily to the bronchoscopists who recognized the benign character of the lesion before the pathologists did. The first two cases which we had here I called slowly growing adenocarcinoma, as I feel sure the great majority of pathologists have up to the last three years. One of these cases came to autopsy after a five-year course characterized by bronchial obstruction and secondary pulmonary suppuration. The tumor was not encapsulated and showed slight evidences of infiltration at its edges, yet it showed no mitotic figures and after five years of growth was less than an inch in diameter. The second case

was operated upon by Dr Churchill after a histologic diagnosis of adenocarcinoma from a bronchoscopic biopsy. It was entirely similar histologically. That patient is entirely well today. Shortly after that operation Dr Churchill called our attention to the reports of similar tumors with a benign clinical course and since that time we have found them relatively easy to recognize if a suitable biopsy specimen can be obtained. Their exact nature is still a matter of controversy and we also do not know whether malignancy can eventually develop.

This patient that we have just discussed today was the third in our entire series. Two bronchoscopic biopsies were reported chronic in

flammation; another two were called hemangiomas—a mistake which could easily be made by one unfamiliar with these tumors because of their vascularity and the last two specimens were finally recognized as adenoma.

The autopsy added comparatively little to our knowledge about this patient. The right pleural cavity showed an acute fibrinous exudate but was free from pus except for a minute pocket immediately beneath the stump of the amputated bronchus and directly overlying the pericardium. The pericardium itself showed an acute fibrinopurulent exudate. Bronchopneumonia had developed in the left lower lobe. Death was undoubtedly due to infection.

INSTRUCTION IN HOSPITAL ADMINISTRATION

IN spite of the fact that there are about 7,000 hospitals in the United States which, annually, care for 7,000,000 bed-patients and 10,000,000 out-patients, it is only within the past two years that organized instruction in hospital administration has been available. This educational experiment¹ was conceived at the University of Chicago and is being carried out in the School of Business.

For registration, a bachelor's degree or a degree of doctor of medicine or of public health is required. A certain amount of instruction in such fundamental subjects as biology, physiology, economics, sociology, and psychology is required, but, of course, may have been included in the candidate's previous education. The courses cover the medical, community and business aspects of hospital administration, employing classroom and "clinical" methods—the latter consisting of observation and supervised field work in hospitals and clinics. The specific courses vary according to the individual—a med-

ical graduate requiring more training in business methods and students with a business background more training in biology and physiology. This preliminary training, which requires from four to six quarters in the University, is followed by an internship of six months to one year in a selected hospital. For a master's degree, a thesis must be submitted.

The need for administrative training has been recognized by the American Hospital Association and by the Rockefeller Foundation for many years, and the University of Chicago is to be congratulated for such a courageous and auspicious beginning.

THE HEALTH ADVANTAGES OF THE UNITED STATES

UNDER the above caption the Metropolitan Life Insurance Company in its statistical bulletin for March, 1936, publishes many interesting comparative figures showing the health advantages which we enjoy over less favored or less enlightened nations.

Cholera and plague are of historical interest to us—there has not been a death from cholera in New York City for forty-three years—but in British India more than 220,000 persons died from cholera, and nearly 46,000 from bubonic plague in the year 1931 alone. In the sixteen states bordering the Atlantic Ocean, where the lesson of vaccination has been well taught, there was only one death from smallpox in 1933, in British India, during the same year, with a population only five times as great, 103,641 smallpox deaths occurred.

The annual typhoid fever mortality in New York and Chicago rarely exceeds one death per 100,000 of population, in Nagasaki, Japan, the death rate from this disease reached 225 per 100,000, in 1931. In La Paz, Bolivia, the 1933 rate was 192 per 100,000, and in Asuncion, Paraguay, it was 187. Delhi, India, registers rates in excess of 100, year after year.

Few of our cities have death rates from measles, scarlet fever, whooping cough or diphtheria in excess of four per 100,000. Bogota, Colombia, Quito, Ecuador, and Karachi, India, register rates of 315, 200 and 175 respectively for measles alone, while La Paz, Bolivia, and San Salvador, Salvador, record rates of 497 and 159 for whooping cough, the Roumanian cities of Jassy and Bucharest have scarlet fever rates of 59 and 39, and in Kingston-upon-Hull, England, and Ghent, Belgium, diphtheria death rates of 42 and 45 prevail.

In 1918 the death rate from influenza in New York City reached the appalling height of 229 per 100,000 inhabitants, approximately the

same influenza mortality is experienced year after year in Fortaleza Brazil. The pneumonia death rate in New York has averaged about 100 per 100,000 in recent years. In Madras the annual rate is approximately 700 and in Valparaiso and Manila approximately 500.

Our country wide tuberculosis mortality has been reduced in thirty five years to 55 per 100,000, about one quarter of the rate which prevailed in 1900. In Manila the rate is about ten times this figure. In Guayaquil Ecuador it is 647, in Callao, Peru 573, in Lisbon Portugal 487 and in Athens, Greece 414.

Likewise with malaria although our death rate has increased in recent years to nearly 4 and in some Southern states is as high as 50 and 100 it cannot be compared to Manaus and Belem in Brazil, with their rates of 517 and 407 with Saigon Cholera in French Indo-China, with its rate of 305 or with San Salvador, where the rates commonly exceed 25.

Such improvement in public health cannot be attributed to changes in natural conditions or to increased resistance on the part of individuals. The credit is due to the intelligent and tireless efforts of our medical and public health services during the last thirty or forty years.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

HUNTER, FRANCIS T. A.B. A.M., M.D. Harvard University Medical School 1924. Assistant Physician Massachusetts General Hospital. Associate Physician, Collis P. Huntington Memorial Hospital. His subject is 'Spray X-Ray Therapy in Polycythemia Vera and in Erythroblastic Anemia'. Page 1123. Address 6 Commonwealth Avenue, Boston, Mass.

HOUSSEY BERNARDO A. M.D. For information see This Week's Issue, page 946, issue of May 7. His subjects are 'The Hypophysis and Resistance to Intoxications Infections and Tumors' and 'Certain Relations Between the Parathyroids, the Hypophysis and the Pancreas'. Pages 1128 and 1136. Address University of Buenos Aires, Buenos Aires Argentina, S. A.

STEIN ARTHUR. A.B., M.D. Tufts College Medical School 1934. Formerly Intern, Worcester State Hospital. Now Intern, Worcester City Hospital. His subject is 'Menorrhagia Occurring at the Onset of Catamenia in a Patient with Thrombopenic Purpura. Report of a Case'. Page 1147. Address City Hospital Worcester Mass.

The Massachusetts Medical Society

SECTION OF DERMATOLOGY AND SYPHILOLOGY

CHANGE IN ANNUAL MEETING PROGRAM

Because of illness it is impossible for Dr. Louis Schwartz of New York to take part in the Annual Meeting Program of this Section. He was to have spoken on Industrial Dermatoses.

In his stead Dr. Marion B. Sulzberger of New York will deliver an address on Definitions and Classifications in Dermatologic Allergy. Dr. Sulzberger is well known for his work on this subject.

MISCELLANY

MAINE NEWS

The Spring Clinic given by the visiting staff of the Eastern Maine General Hospital in conjunction with the Penobscot County Medical Society was held at the hospital on Monday and Tuesday May 13 and 19 1936. The discussion was conducted by Dr. C. H. Beecher and Dr. W. T. Rees of Burlington Vermont.

There were ward rounds in the mornings at 9:30 A.M. and the presentation of cases for discussion in the afternoons at 3:30. The clinic was devoted to general medical and surgical cases. The hospital accepted cases referred to it at no cost for the ward cases other than the regular hospital charges.

On Monday evening May 18 dinner was served at the Bangor House following which Dr. Rees spoke on "Thyroid Disease".

On Tuesday evening May 19 the Penobscot County Medical Society held its regular meeting at the Nurses' Residence of the Hospital. Following this meeting dinner was served after which Dr. Beecher discussed "Arteriosclerotic Disease".

Both Dr. Beecher and Dr. Rees are identified with the University of Vermont Medical School. Dr. Beecher being Professor of Medicine and Dr. Rees Assistant Professor of Surgery.

The Maine Medical Association will hold its Eighty-Fourth Annual Session June 21-23 1936 at Rangeley Maine.

PROGRAM Conferences

Monday June 22 9:30 A.M.

1. Postoperative Abdominal Distention. E. H. Riley M.D. Waterville.
2. Circulatory Failure in Infectious Disease. R. S. Hawkes M.D., Portland.
3. Deep Cervical Involvement from Oral and Nasopharyngeal Infections. C. H. Gordon M.D., Portland.
4. Some Phases of Chronic Uveitis. H. F. Hill M.D. Waterville.
5. Medical Examiners. G. L. Pratt M.D., Chairman Farmington. A round table discussion.

A PLEA FOR IMPROVEMENT OF THE SCIENTIFIC PROGRAMS OF COUNTY SOCIETY MEETINGS

The grammar of medicine is an ever-changing body of fundamentals. Whereas in the other learned professions growth is mainly in the nature of accretion in medicine growth is more likely to effect a transmutation of basic concepts. This was certainly the case when bacteriology was added to the grammar of medicine. So too it was when endocrinology, vitamins and modern psychiatry were discovered and developed. But these transmutations are not invariably effected by epochal discoveries. At times very radical modifications in basic concepts are necessitated by comparatively minor additions to our knowledge. As an instance in point may be taken the recent work on the relation of the physiology of the sympathetic nervous system to such conditions as peptic ulcer and essential hypertension.

The above consideration has a direct bearing upon the education of the doctor when as a neophyte he acquires it in his school and hospital training and more particularly on his continued education after graduation and when he is in active practice.

It is often said half in humor and half in wise denotation, that no one knows so much medicine as the third year medical student. His knowledge is so vast, so precise! He "knows the answers" that is provided he is a good book student. It will require some years of experience and an impressive accumulation of failures to free the young doctor of his conceit. He will only slowly learn the lesson that "grammar" is a body of tools and that art is still elusive. It is a pity then that the young man is not spared the delusion, and that what is taught him is not served with a warning on its tentative nature and with the advice that not only is it subject to change but that indeed periodic change and reinterpretation will be essential to his continued professional growth.

While there are many concerned with the curricula of medical schools, the situation is otherwise with what is termed graduate education. Training for specialization has been accorded a measure of study. But such instruction embraces only a small portion of the medical personnel. Most doctors are and will continue to be general practitioners. They too may periodically desire specialty training as their practice leans heavily in the direction say of obstetrics, gynecology, surgery and so forth. But here our concern is with general instruction for the general practitioner in general medicine. This is necessitated for every man by what we term rather loosely the advances in medicine, but which, as we indicated above arises out of the labile nature of the grammar of our science.

For this type of instruction we can hardly provide formal schooling. There is no fixed curriculum no defined teaching body. Here we need a means so that "he who runs may read" or more fittingly so that he who is in active practice may bring his

knowledge up to the mark without withdrawing from everyday activity. The need for this type of instruction has not gone unrecognized. Indeed, many county associations and academies have organized lecture series for the general practitioner. In the New York Academy of Medicine to cite but one illustration Friday afternoon lectures are available for the practitioners of the metropolis and during the last eight years a Graduate Fortnight, devoted to some one but embracing division of medical practice has been held. These are unique teaching activities as one can readily gather from the programs. They are not devoted primarily to what is the newest at the most recent and the least tried of medical ideas and practices; they are rather résumés of what is known, what is accepted and what has been proved. They are a consolidation of thought and advance in our science.

But even these unique teaching endeavors can reach only a small percentage of our profession. To render the practice more widespread and hence more fruitful, the concept must be instilled into that forum called the county society meeting. Here we have the most numerous and most common meeting place and occasion where and when doctors foregather. The county society meeting should, therefore offer the very best opportunity for this desirable form of instruction.

Our medical journals as a group should prove no less valuable a medium for such education but here we touch on a rather complicated subject and one which we can at this time no more than touch.

Let us apply ourselves more closely to the problem. We grant that the recently graduated physician is a rather raw product. If he continues for ten years without learning more than he knew when he came out of medical school and if he does not readjust his viewpoint his philosophical concepts so to say he will find himself badly behind the procession. How then does he or how should he continue his education? Of course he may take graduate instruction in some specialty or in internal medicine. While this is increasingly the practice among the younger men the number is still very small and it is difficult for the older man who must stay on the job.

Of course he can read his medical journals but most of the journals haven't yet gotten the idea. Their columns are filled with the newest hypotheses, the rare cases and the highly intricate conditions. True occasionally one finds in an annual address or in a contribution by some outstanding scholar an excellent résumé of a given field or subject in such instances this precious material is usually presented in the historical introduction which is likely as not will be skipped by the reader since most "histories" are merely an uncritical recitation of names and dates.

To give due credit we must, however note that the *Journal of the American Medical Association* has in recent months published excellent résumés on therapy and on endocrinology. Also the *Lancet* has been publishing serial résumé articles. These val-

able though they be, are too infrequent and loom small in the bulk of published material

And finally, not all medical men are so to say, eye-minded. Some cannot gain much from the printed page or find the effort too taxing and unprofitable. For them, the human voice is more effective and a more productive medium. The hospital conference, contact with fellow practitioners and meetings, serve best as sources of instruction for a large number of doctors.

This argues, then, for making the county society meeting truly instructive by offering, periodically, résumé programs. This idea is a simple one. Alas, too fatally simple. For, if it is applied crudely and uncritically, it creates a pathetic effect. What can be more boring than being told what is all too well known? Hash is hash even when called a résumé. But we are not after hash in the résumé meeting. We need and desire a recrystallization of thought and knowledge in a given field, a rearrangement of old elements to make a new pattern, a trimming of dead limbs to bring new life into a branch of knowledge. All of which calls for the choice of a suitable subject and a competent essayist.

There is a time and seasonableness for subjects. Not all may be revalued effectively. In many there is nothing new to report, as the old concepts still hold good. But others cry for restatement. There is a sort of nodal point at which progress in a given field may be focused to form a new and clear picture. Such is the instance now in the diseases of the blood, and in the evaluation of the emotional factor in functional disturbance. A year from now the time may be ripe for a résumé of physical therapy in general practice. Nutrition, the diagnosis and treatment of tuberculosis and traumatic surgery are fit subjects for restatement.

But one cannot readily compose a catalogue and schedule of subjects to be so treated which are suitable for differing times and places. The task is not for one man and the problem varies from place to place. But the essential idea is important. A résumé is not a mere restatement of what is known. It is essentially a philosophical task, it is the bringing forth of a new concept, at times furthering, at times reversing, the older concept. It is a critical evaluation, a sifting of older knowledge and its amalgamation with newer knowledge. A résumé is, indeed, of the very nature of the philosophy of medicine, that phase of medicine which is as precious as its science.

IAGO GALDSTON, M.D., *Executive Secretary,*
Medical Information Bureau,
New York Academy of Medicine
2 E 103rd Street, New York City

PATENT MEDICINES SEIZED BY FEDERAL INSPECTORS

Patent medicines are conspicuously present in the U. S. Department of Agriculture report of May 25, 1936. The products seized, their compositions, and the curative claims alleged to be false and fraudulent, are as follows:

"Anti Itch," a petrolatum ointment containing zinc oxide, glycerol, wintergreen and carbolic acid (10.63 per cent). The product was also held to be misbranded under the Federal Caustic Poison Act since it had no label statement of the common name of the poison it contained, no "Poison" warning, and no antidote in case of accidental injury.

"Booth's Hyomei," a solution of eucalyptol, menthol and creosote in alcohol and water, for catarrh, hay fever, catarrhal coughs, croup, bronchitis, catarrhal laryngitis, lung affections and difficult breathing (the product was further misbranded in declaring an alcohol content of 12 per cent when it contained only 9 per cent, and in representing its vapors as antiseptic).

"Bialot Rheumatic Tablets," containing amidopyrine, sodium salicylate, and coated with chocolate, for rheumatism, gout, neuralgia, neuritis and sciatica.

"Diaplex," consisting of the dried leaves and stems of the salt bush, for diabetes.

"Four Leaf Clovers," pink tablets containing boric acid, borax and starch, falsely represented as antiseptic, and for various ailments of women.

"G. S. Alterative Tonic," a solution of plant drugs and potassium iodide in alcohol and water, for pellagra, rheumatism, liver and kidney ailments, and as a tonic.

"H. P. Antiseptic and Healing Balm," a lead oleate ointment not antiseptic as represented, and claimed safe despite its lead content, for a multitude of lesions.

"Hi Test Catarrhal Jelly," a deteriorated salvage drug containing petrolatum, menthol and eucalyptol, for catarrh and hay fever, "Kopp's," a syrup containing the narcotic morphine sulphate, represented as safe for children.

"Lacta Kaolin Alpha," consisting of lactose, kaolin (clay) agar and cocoa, represented as a food, although composed chiefly of nonfood ingredients, "Lacta Kaolin Laxative," of the same composition as the preceding product, with the addition of the coal tar laxative phenolphthalein, without reference to the presence of the laxative drug.

"Mentos," a water solution of sulphur, borax, ammonia and perfume, represented as antiseptic but found on test incapable of killing pathogenic organisms.

"Mother Beach Stomach Tablets," made of sodium bicarbonate, bismuth subnitrate and magnesium oxide, for stomach ulcers, indigestion, and other ailments.

"My-Kel Tooth Powder," sodium perborate and talc, flavored with wintergreen, for keeping the gums firm, building up the tooth enamel, for pyorrhea, and to maintain freedom from mouth infections.

"Quality Sealed Sore Throat Remedy," another deteriorated salvage drug, a solution of potassium chlorate, tannic and carbolic acid in glycerin and water, short of the declared volume, for sore throat.

"Tricasco," a solution of plant extracts, licorice, a laxative and sugar, for forty ailments including consumption, pneumonia, rheumatism, palpitation of

the heart gont gallstones and etomach nleors
"Wards Vitamized Tonic Tablets" containing
iron iodine calcium a fish liver oil and berherine
making claims of vitamin A and D potency that
were found on test to be unsupportable

THE CONTROL OF SILICOSIS BY THE U S DEPARTMENT OF LABOR

Secretary of Labor Frances Perkins has announced
the apppointment of four committees specified below
in the co-operative campaign to lessen the
ravages of silicosis to which 600,000 workers in
mines, quarries, foundries, glass works and other
industries where silica dust may be inhaled are ex-
posed in some degree

RECENT PUBLICATIONS OF THE METROPOLI- TAN LIFE INSURANCE COMPANY

A series of pamphlets for lay readers has been
prepared by the Metropolitan Life Insurance Com-
pany. The titles of these brochures are as follows:

Taking Your Bearings — Emphasizes the value of
periodical physical examinations at various ages.
The old seaman on the cover shooting the sun with
a sextant gives the keynote to the pamphlet. Just
as a seaman uses his nautical instruments to locate
danger spots so with the help of a physician's
knowledge and special instruments one can discover
and avoid many of the physical hazards of life.

Care of the Eyes — Outlines practical methods of
conserving eyesight and describes in simple lan-
guage the more common eye defects and eye dis-
eases.

Sleep — Deals with the importance of sleep, rest,
and relaxation for all ages, emphasizing their close
relationship to health and disposition. Points out
that how well we sleep is as important as how long.

able though they be, are too infrequent and loom small in the bulk of published material

And finally, not all medical men are, so to say eye-minded. Some cannot gain much from the printed page or find the effort too taxing and unprofitable. For them, the human voice is more effective and a more productive medium. The hospital conference, contact with fellow practitioners and meetings, serve best as sources of instruction for a large number of doctors.

This argues, then, for making the county society meeting truly instructive by offering, periodically, résumé programs. This idea is a simple one. Alas, too fatally simple. "Quality Sealed Sore Throat Remedy," another deteriorated salvage drug, a solution of potassium chlorate, tannic and carbolic acid in glycerin and water, short of the declared volume, for sore throat.

"Tricasco," a solution of plant extracts, licorice, a laxative and sugar, for forty ailments including consumption, pneumonia, rheumatism, palpitation of

sion of the insurance principle in relation to hospital service in scientific studies concerning the cost and the organization of medical care and in the education of qualified personnel for studying and administering hospitals and clinics

MORTALITY RATES

Telegraphic returns from 86 cities with a total population of thirty-seven millions for the week ending May 9 indicate a mortality rate of 12.6 as against a rate of 12.0 for the corresponding week of last year. The highest rate (21.5) appears for Tacoma, Wash. and the lowest (4.1) for Waterbury Conn. The highest infant mortality rate (13.1) appears for San Antonio Texas and the lowest for Erie Pa., Fall River Mass. Fort Wayne Ind. Grand Rapids Mich., Hartford Conn., San Diego Calif., Schenectady N. Y., Somerville Mass., and South Bend Ind., which reported no infant mortality.

The annual rate for 86 cities is 18.5 for the nineteen weeks of 1935 as against a rate of 12.6 for the corresponding period of the previous year.

SUMMARY OF DEATHS AND DEATH RATES (ANNUAL BASIS) FROM AUTOMOBILE ACCIDENTS PER 100,000 ESTIMATED POPULATION FOR 86 CITIES FOR CORRESPONDING PERIODS OF 1936 AND 1935

	Week ending		First 19 weeks	
	May 9	May 11	1936	1935
	1935	1935		
Total deaths	163	161	2,665	3,110
Death rate	22.8	22.4	19.6	22.8
Deaths due to accidents in city	131	131	2,057	2,529
Death rate	18.3	18.3	15.2	18.6

—Bulletin, Bureau of the Census

THE RESIGNATION OF DR. DAVID D. SCANNELL

Dr. David D. Scannell has resigned as Surgeon in Chief of the Boston City Hospital effective June 1, 1936.

THE RECORD FOR BLOOD TRANSFUSIONS

Raymond Brix of Paris holds the record for blood transfusions having supplied 98 in one year. Since 1924 he has sold 257 quarts of his blood, without suffering any ill effects. — *Bulletin* New York State Medical Society

THE THREE CENTS A DAY HOSPITAL PLAN

A prediction made at the meeting of the Hospital Association of the State of New York at Buffalo May 23, 1936 is to the effect that the "three cents a day hospital plan" will be popular in the larger cities of New York State.

It was asserted that 33,000 persons in Rochester New York and 90,000 in New York City have subscribed to the plan.

It involves neither charity nor profit according to Mr. Frank Van Dyk, Executive Director of the Associated Hospital Service of New York City.

RECENT DEATHS

UPTON—CHARLES LOUIS UPTON M.D., whose office was at 31 Federal Street, Greenfield Massachusetts died May 25, 1936. Dr. Upton was born at Shelburne Falls in 1870 the son of Olivar and Sarah (Duncan) Upton and after a preliminary education at Arms Academy and Amherst College he matriculated at the University of Pennsylvania School of Medicine and graduated in 1896. Soon afterward he settled in Shelburne Falls where he practiced until he moved to Greenfield in 1925.

Dr. Upton was a Fellow of the Massachusetts Medical Society and the American Medical Association and a member of Lieutenant John J. Galvin Post of the American Legion.

His widow a son, Duncan G. Upton, and a daughter Mrs. Ruth Chase and four grandchildren survive him.

HART—MICHAEL JOSEPH HART M.D., of 1635 Dorchester Avenue Boston died at the Boston City Hospital May 23, 1935.

Dr. Hart was born in Fitchburg Massachusetts in 1871 and was a graduate of Boston College and of the Medical School of Harvard University class of 1896. He practiced in Ashmont for about forty years.

Dr. Hart was not married. Five nieces Mrs. George J. Weldon, Mrs. David Drinkwine, Mrs. W. F. O'Brien, Mrs. Raymond T. Powers and Mrs. William G. Hay and two nephews Paul F. and John J. McElroy all of Fitchburg survive him.

NOTICES

AN AWARD OF ONE THOUSAND DOLLARS FOR A MANUSCRIPT ON A SCIENCE SUBJECT

A cash award of \$1000 is offered by The Williams & Wilkins Company for the best manuscript on a science subject, presented before July 1, 1937.

Literary prizes are relatively common but it is not so usual for a publisher to be bidding for scientific material in this manner.

The publishers put no limitations on the subject matter or manner of handling and none on eligibility for the award. The MS must be in English and "of a sort calculated to appeal to the taste of the public at large." The desired length is given as 100,000 words.

While any MS on a science subject will be considered it is expected that the author will prove to be a man or woman engaged in a scientific pursuit who is possessed of the requisite literary skill to interpret science for that portion of the public which reads books.

To assure authenticity the publishers have enlisted the services of some twenty-five or thirty advisors, these being men of science of wide reputation and assumed competence. One or more of the advisors will pass upon each MS from the viewpoint of soundness and accuracy.

The award will lie in the joint discretion of four judges selected with a view to their especial qualification in choosing the sort of book that will appeal. These are the following: Dr Joseph Wheeler, Librarian of the Pratt Library in Baltimore and chairman of the Book List Committee of the Association for the Advancement of Science, Harry Hansen, reviewer and critic for the *New York World Telegram* and *Harpers Magazine*, Dr Lyman Bryson, Professor of Education of Teachers College, Columbia, and Director of the "Readability Laboratory," and David Dietz, science editor of the *Scripps Howard* newspapers.

Further details concerning the award may be had by addressing the publishers at Mt. Royal and Guilford Avenues, Baltimore, Maryland.

HARVARD UNIVERSITY TRICENTENARY CELEBRATION 1636 1936

SYMPOSIUM ON THE ENVIRONMENT AND ITS EFFECT UPON MAN

August 24 to 29, 1936, at the School of Public Health,
55 Shattuck Street, Boston

Monday

9 30 A.M. The Effects of the Social Environment. Dr Lawrence J Henderson, Abbot and James Lawrence Professor of Chemistry, Harvard University and Dr Elton Mayo, Professor of Industrial Research, Harvard Business School

11 00 A.M. Fatigue. Dr David B Dill, Assistant Professor of Biological Chemistry, Harvard School of Public Health

2 00 P.M. Airborne Disease. Dr Wilson G Smillie, Professor of Public Health Administration, Harvard School of Public Health

3 30 P.M. Bacteria and Pollen in Air. Mr William F Wells, Instructor in Sanitary Science, Harvard School of Public Health

8 00 P.M. Reception to members of the Symposium and their families

Tuesday

9 30 A.M. The Physiological Effects of High Temperatures and Humidities. Dr Cecil K Drinker, Professor of Physiology and Dean, Harvard School of Public Health

11 00 A.M. Industrial Air Conditioning. Mr Constantin P Yaglou, Assistant Professor of Industrial Hygiene, Harvard School of Public Health.

2 00 P.M. The Physiological Effects of High Pressures. Mr Louis A Shaw, Assistant Professor of Physiology, Harvard School of Public Health

3 30 P.M. Industrial Operations in Compressed Air. Mr Ole Singstad, Chief Consulting Engineer on Tunnels, Port of New York Authority

Wednesday

9 30 A.M. Carbon Monoxide Poisoning. Dr Cecil K Drinker

11 00 A.M. Occurrence and Significance of Gaseous Impurities. Mr William P Yant, Supervising Chemist, Health Laboratory Section and Supervising Engineer, Pittsburgh Experiment Station, U S Bureau of Mines

2 00 P.M. The Toxicology of Organic Vapors and Gases. Dr John S Foulger, Haskell Laboratory of Industrial Toxicology, Wilmington, Del

3 30 P.M. The Toxic Dusts. Dr Lawrence T Fairhall, Assistant Professor of Physiology, Harvard School of Public Health

Thursday—Pneumoconioses

9 30 A.M. Causation. Mr Phillip Drinker, Professor of Industrial Hygiene, Harvard School of Public Health

11 00 A.M. Clinical Aspects, Diagnoses, Prevention. Dr W Irving Clark, Physician to The Norton Company and Assistant Professor of the Practice of Industrial Medicine, Harvard School of Public Health

2 00 P.M. Control. Mr Theodore F Hatch, Instructor in Industrial Sanitation, Harvard Schools of Engineering and of Public Health

3 30 P.M. Protective Equipment. Dr Carlton E Brown, Chemist, Gas Section, Pittsburgh Experiment Station, U S Bureau of Mines

Friday

9 30 A.M. The Application of Air Conditioning in Normal Life. Mr Phillip Drinker

11 00 A.M. The Application of Air Conditioning to Hospitals. Mr C P Yaglou

2 00 P.M. A Laboratory of Industrial Toxicology. Dr W F von Oettingen, Director, Haskell Laboratory of Industrial Toxicology, Wilmington, Del

3 30 P.M. A Laboratory of Industrial Hygiene. Mr Warren F Cook, Chief Industrial Hygienist, State Department of Health, Hartford, Conn

Saturday A.M.

Demonstration in the Harvard School of Public Health and visits to the Industrial Clinic, The Norton Company, Worcester, Mass., The Fletcher Granite Company, West Chelmsford, Mass., The Fatigue Laboratory, Harvard Business School

To cover the expenses of the symposium a fee of \$25 will be charged those who attend. For further information address Marian Dale, Secretary, 55 Shattuck Street, Boston, Mass.

TRICENTENARY SESSION OF THE HARVARD MEDICAL SCHOOL

SEPTEMBER 14 AND 15, 1936

As part of the University celebration, the Medical School and the Medical Alumni Association invite the graduates of the School to return on September 14 and 15 for the Medical School Exercises.

and Medical Alumni Reunion. These will immediately precede the final Cambridge exercises on September 16, 17 and 18.

The Medical School Exercises will include

Demonstrations, special clinics, discussions and exhibits at the various hospitals associated with the Harvard Medical School.

Four carefully planned symposia programs presented by the Harvard Medical Faculty on Nutrition and the Deficiency Diseases

Chairman Dr. George R. Minot

The Nervous System: Central and Sympathetic

Chairman Dr. Walter B. Cannon

The Infectious Diseases

Chairman Dr. Hans Zinsser

The Endocrine Glands

Chairman Dr. J. Howard Means

The annual meeting and the dinner of the Harvard Medical Alumni Association will be held on the evening of September 15 in Vanderbilt Hall. This meeting has been postponed from its usual time in June in honor of the Tercentenary and to encourage the return at this time of as many graduates as possible.

"OPEN HOUSE"

July, August and September

The Tercentenary Celebration begins on July 6, 1936, when the University places its various buildings and activities "on view." Most of the departments of the Medical School and the affiliated hospitals will keep open house for all or part of the summer. During this time one or more members of the staff of each department will always be available to receive returning graduates or interested visitors and show and explain the routine activities or such demonstrations and exhibits as the department may offer. Further information as to items of special interest, dates and times will be published in the Medical Alumni Bulletin and will be available during the summer at the Tercentenary Office in Cambridge.

PROGRAM OF THE TRICENTENARY SESSION OF THE MEDICAL SCHOOL

Monday, September 14

9:00 A.M. 12:30 P.M. Clinics and demonstrations

The "open house" demonstrations and exhibits of the summer will be continued during this morning. The members of the staffs will be present to discuss their work informally and many of the departments and hospitals will offer special clinics and demonstrations. The final program will be announced at a later date in the Medical Alumni Bulletin.

12:30 P.M. Buffet luncheon in Vanderbilt Hall

~ 00:5-00 P.M. Harvard Medical School, Building D

Introduction to the Symposia

Dr. David L. Edsall, Dean Emeritus

Nutrition and the Deficiency Diseases

Chairman Dr. George R. Minot

Dr. J. L. Gamble — Intracellular Fluid and Its Maintenance

Dr. C. M. Jones — Protein Deficiency

Dr. C. W. Heath — The Deficiencies of Circulating Hemoglobin

Dr. W. B. Castle — The Relationship of Defective Nutrition to Changes in the Gastro-Intestinal Tract

Dr. S. B. Wolbach — Vitamin C and the Formation of Intracellular Material

Dr. K. D. Blackfan — Sub-Optimal Nutritional States and Partial Vitamin Deficiency

Dr. P. Howe — Oral Pathology in Relation to Avitaminoses

Dr. M. B. Strauss — Nervous Disorders Arising from Defective Nutrition

Dr. E. P. Joslin — Present Aspects of Diabetes

Monday evening is held open for possible Medical class reunions and hospital reunions.

Tuesday, September 15

There will be two simultaneous sessions on Tuesday morning.

(A) 9:30 A.M. 12:30 P.M. Harvard Medical School Building C

The Nervous System: Central and Sympathetic

Chairman Dr. Walter B. Cannon

Dr. J. C. White — Surgery of the Sympathetic Nervous System

Dr. A. Rosenbluth — Chemical Mediation of Nervous Effects

Dr. J. B. Ayer — The Use of Prostigmine in Myasthenia Gravis

Dr. H. Davis — The Electrical Activity of the Human Brain

Drs. F. A. Gibbs and W. G. Lennox — The Electrical Activity of the Brain in Epilepsy

Dr. S. Cobb — Cerebral Circulation

Dr. S. Weiss — Syncope and Collapse

Dr. T. J. Putnam — The Pathogenesis of Multiple Sclerosis

(B) 9:30 A.M. 1:30 P.M. Harvard Medical School Building D

The Infectious Diseases

Chairman Dr. Hans Zinsser

Dr. Hans Zinsser — Recent Advances in the Study of Typhus Fever

Dr. C. F. McKhann — The Immunological Application of Placental Extract

Dr. W. G. Smittle — Epidemiological Studies on the Virus of Influenza

Drs. C. S. Keefer and W. W. Spink — Immune Reactions in Gonococcal Infections

Dr. A. W. Sellards — Yellow Fever

- Dr C Lyons — Antibacterial Immunity in Hemolytic Streptococcal Infections
 Dr E S A Robinson—The Antiserum Treatment of Pneumonia from the Standpoint of Public Health
 Dr M Finland—Some Aspects of Pneumococcus Infection in Man
 Dr R P Strong—Studies on Filarioides
 Dr D L Augustine—Trichinosis, Incidence and Diagnostic Tests
 Drs H Pinkerton and G M Hass—Cultivation of Rickettsia in Tissue Culture

12 30 P M Buffet luncheon in Vanderbilt Hall

2 00 5 00 P M Harvard Medical School, Building D

The Endocrine Glands

Chairman Dr J Howard Means

- Dr G B Wislocki — The Blood Supply to the Hypophysis
 Dr H B Friedgood—The Nervous Control of the Anterior Hypophysis
 Dr E C Cutler—Diabetes Insipidus Its Relation to Hypophysis and Thyroid
 Dr J C Aub — Hypophyseal Parathyroid Relationships
 Dr A B Hastings—Factors Governing the Calcium Equilibria of the Body
 Dr F Albright—The Action of the Parathyroid Hormone upon the Skeleton
 Dr E D Churchill—The Surgery of the Parathyroids
 Dr W T Salter—The Genesis of Thyroid Protein

6 00 P M Annual Meeting of the Medical Alumni Association

7 00 P M Dinner of the Alumni Association in Vanderbilt Hall

REPORTS AND NOTICES OF MEETINGS

THE BOSTON UNIVERSITY SCHOOL OF MEDICINE ALUMNI

Describing the relationship of mental factors and disease to illness and the fact that psychiatry is in close touch with many community activities, Dr Winfred Overholser, State Commissioner of Mental Diseases, in an address delivered recently before the annual gathering of the Boston University School of Medicine Alumni at the Hotel Kenmore, declared that his Alma Mater and the Commonwealth of Massachusetts are two pioneer agencies in the original study and continuing development of this field.

"Psychiatry," he said, "like other branches of medicine has much to learn but it presents a fertile field for research."

The dinner was featured by a special reunion of the 10-year class of 1926 under the direction of Dr Ralph Wells of Newton Centre. Dr Cecil Clark of Newton toastmaster, introduced the speakers who, in

addition to Dr Overholser, included Dr Daniel L Marsh, President of Boston University, Dr Alexander S Begg, Dean of the School of Medicine, Dr Reginald Fitz, Director of the Evans Memorial, Dr Howard Clute, Professor of Surgery, and Walter Mulvihill of Worcester, president of the senior class, Dr Rudolph Jacoby of Newton, and Dr Samuel N Vose of Newton Centre, arranged the dinner.

Officers for 1936-37, who were elected, are the following doctors: President, David L Belding '13 Hingham; First Vice-President, C Wesley Sewall '14, West Roxbury; Second Vice-President, Nathan H Garrick '15 Boston; Secretary, Rudolph Jacoby '11, Newton; Treasurer, Harold W Ripley '17 Braintree; Auditor, Samuel N Vose '18, Newton; Directors, Frank E Barton '24, Newton, Cecil W Clark '15, Newton, Leighton F Johnson '15, Norwood, John A Rockwell '99, Cambridge, Helmuth Ulrich '11, Newton.

Speaking further on the importance of psychiatry, Dr Overholser said "The field of psychiatry has long since outgrown the walls of what were formerly known by the dismal name of 'asylums' Today, psychiatry is no longer the orphan of medicine, but is recognized generally as a specialty which has its bearing on every other specialty of medicine. The surgeon, the internist, everyone who today is dealing with the sick, is recognizing more and more the importance of mental factors in disease and the fact that physical disorders have their mental concomitants. This fact was recognized in different terms by the men who founded the Boston University School of Medicine, and it is gratifying to us, as alumni of that school, to realize that the founders were men who were ahead of their times."

"Psychiatry, in addition to its contacts with other branches of medicine comes into touch with many community activities as well. I need hardly mention to you the program in which Massachusetts was a leader, dealing with the early recognition of mentally retarded children in the public schools, of that pioneer activity of Dr Thom in developing the habit clinics in the child guidance work, and of the important pioneer activity of Massachusetts under the Briggs law of assisting the courts in their difficult task of dealing with defendants on the basis of a knowledge of their mental condition. It is pleasing to note that this latter activity has been recognized by the Federal Department of Justice and Public Health Service in selecting Boston as the first place in the country to establish in the Federal Courts a system of psychiatric advisers to the Court."

"Psychiatry, like other branches of medicine, has much to learn, and presents a fertile field for research. Much research is being done, both in Massachusetts and elsewhere, under the auspices of the State and of private foundations. Much needs to be learned about the method of prevention of mental disorders and, in this field again, psychiatry has a heavy obligation to the community in which it must not be found wanting."

"The Commonwealth of Massachusetts through its Department of Mental Diseases is giving every possible encouragement to the work of research and prevention. Massachusetts was indeed the first state to recognize by statute the fact that a state even if it gives every possible care to the mental patients within its hospitals is not fulfilling its entire duty to the community unless it takes steps to direct research activities toward the prevention and earlier onset of mental disorders with a view not only to decreasing the sum total of human misery but of lessening as well, the burden upon the taxpayers of supporting its evergrowing institutions."

THE INTERNATIONAL CONGRESS OF PHYSICAL MEDICINE AND PHYSIOTHERAPY

The sixth International Congress of Physical Medicine and Physiotherapy which was held in London, May 12 to 16 1936 under the patronage of the British Government was attended by widespread attention throughout England. The section on Physical Education was a prominent feature of the program which contained reports on recent developments in all branches of physical medicine and physical therapy. It was presided over by Sir Robert Stanton Woods M.D. one of the physicians to the late King George.

At this Congress Dr. William D. McFee was elected to Honorary Membership in the permanent organization the International Association of Physical Medicine and Physiotherapy this being the first time this honor has been conferred by the association.

NEW ENGLAND OPHTHALMOLOGICAL SOCIETY

The April meeting of the New England Ophthalmological Society was held April 31 in the Massachusetts Eye and Ear Infirmary. After the reading of the minutes of the previous meeting Dr. Benjamin Sachs presented the first case. A forty year old Italian male entered complaining of pain in the eyes of four weeks duration photophobia ptosis but no loss of vision. A bilateral enlargement of the lacrimal glands was found each being about the size of an almond the eyes being red and dry and there was evidence of old posterior synechia on the left. The tintinn was negative and the patient was given potassium iodide. A chest plate showed marked hilus thickening and it was felt that the condition was probably due to tuberculosis. A diagnosis of dacryoadenitis was made.

Dr. Sachs next presented a fifty-six year old male who has been treated for syphilis since 1906. had gonorrhea in 1904 and pulmonary tuberculosis in 1917. Examination showed a yellow jelly-like mass under the conjunctiva on the left eye without accompanying symptoms. There were other small nodular swellings involving both lids of both eyes as well as in the neck and legs. The patient

showed an eosinophilia of 6 per cent. It was felt that this was probably a case of sarcoma of the eyelid, which condition is said to respond well to arsenic and x-ray treatment.

Dr. Sachs then presented a case of staphylococcal retinitis, that in May 1935 presented a small right paracentral scotoma. This winter the patient developed grippe and following this noticed black spots before his right eye. In January a swelling of the right disc and a vitreous opacity was noted. Under observation this patient developed pathology involving the macula and a typical star shaped figure was demonstrated. The blood pressure skull plates and urine were negative.

Dr. Sachs then presented a case of unilateral exophthalmos which has developed following subtotal thyroidectomy in July 1935. The question arose as to how to stop this process but without a definite decision.

The next patient had been struck on the head five years previously. He was unconscious for two hours and some months later noticed a hard lump on the forehead. The patient had had dizzy spells which terminated in profuse epistaxis and foul discharge from the nose and he had also had several epileptiform attacks. Gradually he developed exophthalmos and a severe pain in both eyes during the past few weeks. Examination showed a non-tender hard mass not fixed to the skin in the mid forehead exophthalmos rather swollen lids and a limitation of the movements of the eyes. The fields and fundi were normal. Neurological examination and spinal fluid were normal. Skull plate showed destruction of the frontal bone and ethmoid. A diagnosis has not yet been made.

Dr. James Regan presented a case of a girl who following spinal anesthesia, developed photophobia and limitation of motion of the right eye due to paralysis of the right abducens nerve. During the three months since that time she had gradually improved. There are several examples in the literature of ophthalmoplegia following the administration of spinal anesthesia. Of these paralysis of the sixth nerve is most common but such cases usually clear up much more quickly than in this instance.

The seventh case was monocular pigmentary degeneration of the retina. There are eight other authentic cases reported in the literature. Dr. Wells demonstrated a pair of spectacles that can be used, while the patient is lying on his back for reading at right angles.

Dr. Algernon B. Reese delivered the paper of the evening on "Changes that Occur in a Detached Retina." The frequency with which central vision is poor following operations for re-attachment of the retina is well known. Statistics show that about 32 per cent of such patients give a central vision of 20/30 or better after re-attachment. It was also shown that the lapse of time between attachment of the retina and operation was an important factor. Microscopic examination of the detached retina shows that there are cystic spaces formed especially in the region of the macula. Those cases that

chimecas left behind him "a record of the highest civilization North America had known"

The author informs us in his summary of the Medicine-Men that the theory of disease-cause which is most universal and popular in the New World, is that of the disease-object intrusion. This is the theory which holds that sickness is due to the presence in the body of some foreign object, such as a fish bone, a stick, a stone, or a bit of hair. In addition, the following causes for illness, given in descending order of their importance, may be listed: soul loss, sorcery, spirit intrusion, and finally, breach of taboo.

He further tells us that the supernatural of course plays a major part in all the Indian's healing ceremonies. But the medicine-man's job is to inspire faith on the part of his patient, and to use some common sense in his treatment. Even today, he says, the treatment of many a modern charlatan is often as harmful and horrible as that of the Indian medicine man.

There is much of great interest in the part of the book devoted to child-bearing in the Indian races.

Surely the lover of Indian history will be impatient to read the fascinating pages of Dr Corlett's book.

Aids to Medicine James L Livingstone Fifth Edition 422 pp Baltimore William Wood and Company \$1.50

This is a compendium of medical knowledge which is one of a series of "Students' Aids" printed in Great Britain and distributed here by William Wood and Company. It is a volume of four hundred odd pages, four by six and a half inches and three-quarters of an inch in thickness, making a handy pocket volume for medical students to read in the subways and other such places. It covers a comprehensive variety of diseases and for that reason makes interesting random reading. The views expressed are essentially conservative and sound.

Venereal Disease Information Prepared by the U S Public Health Service Washington Government Printing Office

It is the purpose of the Public Health Service in issuing this publication to provide in condensed form a monthly summary of the scientific developments in the diagnosis, treatment, and control of syphilis and gonorrhea. More than three hundred American and foreign journals are reviewed for this work. Abstracts are made of articles describing laboratory, pathologic, and clinical work in the field of venereal diseases.

The most important literature on every phase of the subject is presented in the form of brief abstracts that are easily read. An index for the year is published with the December issue.

During the past year thousands of physicians found this publication useful in enabling them to keep abreast with developments in venereal disease work.

The cost of this publication is only fifty cents per annum, payable in advance to the Superintendent of Documents, Government Printing Office, Washington, D C. It is desired to remind the reader that this nominal charge represents only a very small portion of the total expense of preparation, the journal being a contribution of the Public Health Service in its program with State and local health departments directed against the venereal diseases. If you wish to secure the valuable service which this monthly magazine provides, send fifty cents to the Superintendent of Documents, Government Printing Office, Washington, D C.

Demonstrations of Physical Signs in Clinical Surgery Hamilton Bailey 287 pp Fifth Edition, Revised Baltimore, William Wood and Company \$6.50

The popularity of this volume is evidenced by the fact that five editions have been required since it first appeared in 1927. Practically every physical sign of value in surgical diagnosis is clearly yet briefly described. The very generous use of illustrations, many of them colored, adds greatly to its clarity. It has proved itself a most useful book for both students and practicing physicians.

Les Acquisitions Nouvelles de L'Endocrinologie R Rivoire 305 pp Paris Masson et Cie 36 fr

This book on newer conceptions in endocrinology is well written and exceptionally well up-to-date. The reviewer has checked certain data contained in this monograph, and he found them remarkably accurate.

There are six chapters in all. One each is devoted to parathyroid, suprarenal, pancreas, ovary, testes, and pituitary glands.

It makes easy and interesting reading to one conversant with French and the price is reasonable. It is a valuable addition for the endocrinologist.

Diseases of the Nose and Throat for Practitioners and Students C J Imperatori and H J Burman 723 pp Philadelphia J B Lippincott Company

This volume is designed as a textbook for the general practitioner and the senior medical student. It gives a description of many of the more common diseases and a few of the less common ones, and discusses their symptoms, diagnosis, treatment, pathology and causation. It is in outline form and is carefully illustrated.

Considering the point of view of the readers for whom the book is intended, there is far too much emphasis on the details of operative technique. Many of the more serious illnesses, moreover, such as malignant neoplasm, have been treated in a very superficial manner. The book is well prepared from a publisher's standpoint, but as a textbook it is superfluous, since there are many other excellent treatises on the same subject.

NUMBER 24

ACUTE CHOLECYSTITIS*

A Study of Conservative Treatment

BY CHARLES D. BRANCH, M.D.† AND ROBERT ZOLLINGER, M.D.†

INTRODUCTION

MODERN surgical opinion as expressed in recent articles tends to favor early operation in the treatment of acute cholecystitis. The impression is given that acute cholecystitis, because of the consistently high mortality rate should be considered an acute surgical emergency and that delay is no more to be tolerated than in acute appendicitis. However an analysis of these articles clearly shows that the so-called early operation is not always an immediate one, but may be performed during a period varying from several days to two weeks following the onset of the acute attack. It would seem, therefore, that there are relatively few surgeons who routinely advise immediate operation.

Miller,¹ 1930 and Graham² 1931 were among the first to call attention to the better results which they and their associates obtained when early operation was employed. Miller advised immediate operation in those cases in which the symptoms were severe and persistent and also in doubtful cases. Graham called attention to the reduction in mortality in his series from eleven per cent to five per cent following the attempt to operate in cases of acute cholecystitis forty-eight hours or less after the onset of the attack. Stoue and Owings³ 1933 have been the most dogmatic in sponsoring prompt operation and have concluded that immediate operation is the method of choice in all types of acute inflammation of the gallbladder. Zinniger⁴ 1932, was not so positive that all cases of acute cholecystitis should be submitted to immediate operation, advising this only for those cases in which the symptoms were severe and the leucocytosis was high. In the remaining cases, if the symptoms did not subside within forty-eight hours, operation was strongly urged. The majority of the other recent articles temporized and advised, what seemed to us to be, a conservative type of treatment. Smith,⁵ 1933 and Behrend,⁶ 1934, have been staunch advocates of conserva-

tive treatment for all cases unless free peritonitis existed.

Because of the divergence of opinion we have analyzed the cases of acute cholecystitis seen in the Peter Bent Brigham Hospital during the past twenty years in an effort to draw our own conclusions regarding the merits of either method of treatment. A conservative method has been generally used in the treatment of the 235 patients with acute cholecystitis treated during that period. As the accompanying chart (table 1)

TABLE 1

Years	10-19	20-29	30-39	40-49	50-59	60-69	70-79	80-89	Total	Deaths

Female		15	27	37	45	31	7	1	163	(9.3%)

*Three cases were not submitted to surgery

shows, there has been an increase in the incidence of these cases during the last three years. Whether this is due to the "depression", which Steiner⁷ believes to have caused procrastination in chronic cases is difficult to determine for it may be that there has been a tendency to operate before the acute attack has completely subsided. This would increase the number of cases in which patients showed evidence of acute inflammation at the time of operation. Undoubtedly there have been additional patients with acute

cholecystitis admitted to this hospital, but all those cases which were in the least questionable have been omitted

PATHOLOGY

It is generally agreed that calculi are usually associated with acute cholecystitis and that they are often found impacted in the neck of the gallbladder or cystic duct. The recent report of Andrews⁸ indicates that in all such cases with obstruction of the cystic duct there is vascular damage, the extent of which determines the lesion of the gallbladder wall. That there is a single factor causing the circulatory stasis preceding this damage has not been demonstrated. This has been assumed to have been due to the impaction of a calculus, which, by direct pressure, closed the vein and lymphatics. Kreider,⁹ in 1933 showed by injection of the veins in cases of cholelithiasis that an impacted stone could not cause venous stasis. He demonstrated that there was a venous plexus in the mucosa, a cystic plexus which was found just outside the muscularis and accompanied the branches of the cystic artery, and unpaired cystic veins. These cystic veins varied greatly in size, number and course, some of them accompanying the branches of the cystic artery toward the neck of the gallbladder, others carrying blood around the sides of the gallbladder, or from its deep surface, directly into the liver by way of the gallbladder fossa. He maintained that the cystic veins do not run close enough to the cystic duct to be affected by the pressure of the stone in the duct and that only a small fraction of venous drainage occurred by way of the neck of the gallbladder.

A second possibility is that the edema, which is present to a varying degree in all these cases, obstructs locally by direct pressure the lymphatics and lesser venous drainage, thus causing vascular damage. This of course would require an explanation for the formation of the edema, which might be caused by the absorption of the bile salts. Andrews and Henry¹⁰ have suggested that a too strong concentration of the bile salts provokes an inflammation capable of producing absorption, an explanation with which we are in agreement.

SYMPTOMATOLOGY

The symptomatology of acute cholecystitis may be quite varied although the classical description still emphasizes the occurrence of pain in the right upper quadrant with radiation to the angle of the scapula. It would be expected that most patients would complain of pain in the right upper abdomen. This has not been the rule in this series, for epigastric distress was nearly as common, and occasionally the chief complaint was localized pain or tenderness

in the left upper or right lower quadrant. Since in many patients the gallbladder was found to be distended upon operation, the varied symptomatology could be explained by previous experimental observations made in this hospital.¹¹

It has been observed that mechanical distention of the gallbladder and common duct in a conscious patient produces epigastric distress. The conclusion was drawn that the epigastric distress represented a true visceral type of pain, and that in cases of cholelithiasis it usually indicated overdistention of the gallbladder or ducts as the result of a stone located in, or tending to pass into, the cystic or common duct. Since the cystic duct or ampulla of the gallbladder is frequently blocked by a calculus, epigastric distress should be one of the more frequent initial symptoms of acute cholecystitis. In this series, according to the notations made by the surgeon or pathologist, a stone was impacted in the ampulla or cystic duct in 112 cases, or 46.4 per cent. From a study of these cases it is seen that the initial pain occurred in the epigastrium in eighty-eight, or 78.5 per cent. The pain in twenty of the above instances later shifted to the right upper quadrant with the increasing severity of the attack. This close relationship between the number of patients in which there was found definite evidence of cystic duct obstruction, and in which initial epigastric distress was present, is in accord with the experimental findings. In acute cases in which patients have epigastric distress and in which a cholecystostomy is done, the operator should be doubly certain to search for, and to remove, the probable impacted calculus. Furthermore, in those patients who have epigastric distress but show no evidence of acute cholecystitis the possibility of a stone in the common duct is suggested. This has been emphasized previously by one of us.¹²

Since referred pain to the right upper quadrant or back could not be reproduced by mechanical distention of the gallbladder or common duct, we concluded that referred pain to the right upper quadrant or back probably indicated an inflammatory process. The inference was drawn that the pain was referred over a peritoneocutaneous radiation (Morley¹³), instead of the widely accepted visceral sensory reflex of Mackenzie.¹⁴ In other words, the referred pain in gallbladder disease depends upon stimulation of the cerebrospinal nerves supplying the involved peritoneum. The attack of acute cholecystitis may begin in the form of epigastric distress due to distention of the cystic duct by a calculus, and later pain in the right upper quadrant develops as the result of the inflammatory process in the gallbladder stimulating the overlying peritoneum. Likewise, the associated pain in the back would indicate involve

ment of the cerebrospinal nerves supplying the painful segment. Inflammation would extend around the cystic and common ducts involving the cerebrospinal nerves in the gastrohepatic ligament, and in this manner pain would be localized in the back. We believe that the cerebrospinal nerve supply of the gastrohepatic ligament is the same as the margins of the diaphragm, that is, the lower six intercostal nerves. We know that the pain in the back is usually in the areas supplied by one or more of the lower six intercostal nerves.

An analysis of the pain in these patients with acute cholecystitis shows that eighty-seven or thirty-seven per cent complained of pain in the epigastrium originally and throughout their illness. According to Morley's theory it would be expected that this was true visceral pain and that, unless contact of an inflammatory process with the peritoneum occurred there would be no evidence of pain in the right upper quadrant or muscle spasm. Morley explains muscle spasm as due to a peritoneumotor reflex all within the cerebrospinal nerves. In fifty-three of these eighty-seven cases there was no evidence of rigidity or muscle spasm. However, in thirty-four instances there was evidence of rigidity. In twenty other patients there was pain in the epigastrium originally, but with the continuance of the disease process, the pain shifted to the right upper quadrant. According to our belief this is due to an inflammatory process coming into contact with the peritoneum and abdominal rigidity would be expected. We found that nineteen of these twenty patients had definite muscle spasm. In the case of 115 patients complaining of pain originally and continuously in the right upper quadrant there was muscle spasm in ninety-four, we would expect to find rigidity in all of these but in twenty-one there is no mention of this in the history. The remaining cases of the series were unusual in that patients had pain originally in the right lower quadrant in nine instances in the left upper quadrant in two cases while in two patients the pain was localized in the chest.

Although referred pain may result from other stimuli it is usually the result of an inflammatory process. Patients complaining of continuous pain in the right upper quadrant are considered as having an extensive inflammatory process involving the overlying peritoneum and extending down the ducts. It would, therefore, be expected that this group would show a high incidence of referred pain. Pain was referred to the back in eighty-six, to the shoulder in nineteen, and along the right costal margin in ten. In regard to epigastric pain referred pain was found to have occurred in only a few. Occasionally the pain extended to the back except in a few cases when it was localized to the angle of the right scapula.

Nausea and vomiting are usually associated with gallstone colic. In a previous communication we have shown that involuntary vomiting occurred in only twenty-five to forty-four per cent of the patients with chronic cholecystitis and cholelithiasis without evidence of a stone located in the extrahepatic ducts. The incidence jumps to approximately ninety per cent in the cases of common duct stone. In acute cholecystitis, nausea and vomiting are common symptoms. Nausea was found in 197 of our 235 cases, while involuntary vomiting was found in 176 cases or 74.9 per cent. By involuntary vomiting is meant spontaneous vomiting which the patient does not induce in an effort to relieve nausea. In the experimental work carried out it was found that the distention of the gallbladder did not produce vomiting while distention of the common or cystic duct caused involuntary vomiting. Therefore, it is probable that, in the 176 cases in which vomiting occurred, a calculus was impacted in the cystic duct or had passed through the cystic or common duct.

The physical findings of these patients upon admission to the hospital were not remarkable. As expected, tenderness was present in a great majority, localized in the right upper quadrant in 151 patients, in the epigastrium in twenty-four over the entire right abdomen in twenty-five and in the right lower quadrant in four patients. It was interesting to note that two of the patients showed well localized tenderness in the left upper quadrant. Involuntary muscle spasm was found in 143 of the patients. This has been analyzed above in relation to the onset of the pain. A mass was palpated at the time of admission in seventy-six of these patients.

TREATMENT

The treatment of these patients with acute cholecystitis was on the whole by conservative methods. Thirty-four or 14.4 per cent were submitted to immediate operation. This was done, in the majority of instances, because of signs of definite peritonitis, or because of suspicion of impending perforation of the gall bladder.

Perforation was suspected in those patients in which there was a rising leukocytosis and an increasing tenderness and rigidity in the right upper quadrant. The remaining 195 patients who were submitted to operation were treated conservatively. They were kept in bed preferably in Fowler's position. Food was denied them and in recent years fluids, particularly dextrose solution, were administered subcutaneously and intravenously. The patients' temperatures routinely fell most of them reaching a normal level and only a few remaining above 99° F. This is shown graphically in the accompanying chart (figure 1). The average period necessary for

this to occur was 47 days. It is our belief that a period of five to seven days, or perhaps longer in a few cases, gives an opportunity for the patient's condition to improve and for the acute inflammatory process to subside, thus simplifying operation. That the danger of delay is not great is shown by the relatively few cases of generalized peritonitis. Judd and Phillips¹⁶ reported 508 cases of patients with acute cholecystitis, only three (0.59 per cent) having generalized peritonitis. Graham¹⁶ reported two cases occurring in his series, an incidence of 1.47 per

ery of calculi in nineteen, or 8.3 per cent of the 229 cases.

The gallbladder was found to have perforated in twenty-one patients, or 8.8 per cent of those operated upon. Six of these had been operated upon immediately following their admission to the hospital, the other fifteen were found at the time of delayed operation. In those patients operated upon at the time of delayed operation there had not been a spread of peritonitis. Careful analysis of these cases demonstrates that sixteen showed rigidity, while the remaining five were not suspected of having much in the way of an inflammatory process. Those patients who did not have rigidity complained of pain in the epigastrium, and they were found to have well walled-off abscesses of rather small size near the liver surface.

Calculi were found in 214 of the patients, they were mentioned as blocking the cystic duct in sixty-six instances, and as being impacted in the ampulla in forty-six additional cases. As has been mentioned before, common duct stones were found in nineteen of the patients whose biliary tract was explored. While this does not account for the total of 176 cases in which involuntary vomiting was a feature, at least it is significant, as it is an incidence of 63.6 per cent, and many of these patients may have had temporary blocking of the cystic duct by a stone which had been passed or had fallen back into the gallbladder at the time of operation. In recent years these patients have been given large amounts of fluids containing dextrose postoperatively to aid in the repair of liver damage. In patients on whom cholecystectomy was done the drain was removed routinely on the third or fourth day. In those cases in which there was no complication the patient was placed on a high carbohydrate and low fat diet about the third day following operation.

The complications of upper abdominal operations are usually associated with the respiratory tract. Surprisingly enough in this series there were only eight patients who developed bronchopneumonia, atelectasis occurred in two additional cases, and pleurisy with effusion in two others. The remaining complications are listed on the accompanying chart (table 2).

In this series of 235 cases there were twenty-seven deaths, three occurring among the six cases that were not submitted to operation. The operative mortality for the remaining 229 cases was 10.4 per cent (twenty-four deaths). Seven (20.5 per cent of the cases submitted to immediate operation) were immediately operated upon while the seventeen other deaths followed an interval, 8.7 per cent of the 199 having had a delayed operation. Cholecystectomy had been done in nineteen of these, cholecystectomy with exploration of the common duct in three, and cholecystostomy in two.

FIGURE 1 Solid line—Temperature on admission. Dotted line—Temperature following a period of conservative treatment.

cent. Our experience has been much the same in this group of acute cholecystitis. Generalized peritonitis was found to be present in six or 2.55 per cent. Because of the ability of the structures about the region of the gallbladder to wall off this area, and also because of the vascular supply of the gallbladder itself, this would be expected. Graham¹⁶ concluded that it was untenable to make an analogy between acute cholecystitis and acute appendicitis for these reasons, and the same inference can be drawn from our group of cases.

Cholecystectomy was performed in 205 of the operative cases; in the remaining twenty-four, cholecystostomy was carried out. The majority of these twenty-four cases were patients in whom the condition was critical and who would not survive a more extensive procedure. Since cholecystectomy is the operation of choice, we believe that a period of waiting permits this operation to be carried out in most instances and does not necessitate a second operation which is so often required when cholecystostomy has been done. This delay also permits the inflammatory process to subside and thus eliminates to a large extent, the danger of spreading the infection to the general peritoneal cavity. Nine of the twenty-four cases required a subsequent cholecystectomy, with one fatality (11.1 per cent). The common duct was explored in forty-five patients in our series with the discov-

The death of the patients who were operated upon immediately was due, in a large part, to their poor condition. Three were moribund upon admission and operation was undertaken only as a last resort. The cause of death in those patients in whom operation was delayed was varied, four were caused by bronchopneumonia, while three others showed evidence of emboli lodging in the pulmonary artery and one going to the brain. Five cases might have terminated differently if too extensive an operative procedure had not been carried out. If cholecystostomy had been done the chance for the spread of infection would have been lessened. It is probable that in such cases simple

drainage is the preferred method of treatment. Liver damage, as shown by cholangitis and localized abscesses, was the most important etiological agent in three patients, while in the remaining two the cause of death could not be determined.

Follow up studies were possible in 152 of the 208 patients who survived operation. These patients were seen after a period of at least two years following operation and a large number at least five years afterwards. In 110 of these patients there was no recurrence of symptoms either in the form of epigastric distress or colic, nor had gastrointestinal symptoms returned. Sixteen patients complained of definite pain either in the epigastrium or the right upper quadrant. In some of these the pain was described as a colic similar to that occurring before operation. Fifteen patients complained of indigestion and gaseous eructation following operation. In five patients subsequent attacks of colic suggested that reoperation be performed which resulted in the finding of a common duct stone. One died of carcinoma of the head of the pancreas one and one-half years after operation. Five individuals died of other causes before the period of two years had elapsed. In the 152 patients seen seven postoperative hernias had developed.

SUMMARY

An analysis of 235 cases of acute cholecystitis treated by conservative surgical methods is presented.

The location, significance and mechanism of pain in acute cholecystitis is discussed in relation to previous experimental studies.

Thirty four or 14.4 per cent, were submitted to immediate operation. The remaining 195 patients who were operated on were treated conservatively for an average of 47 days before operation.

Generalized peritonitis was found to be present at operation in six, or 2.5 per cent, of the cases.

Cholecystectomy was performed in 205 cases and cholecystostomy in twenty four cases.

There were twenty seven deaths among the 235 patients, three being in the group not submitted to operation. The operative mortality for the entire series was 10.7 per cent. In the case of immediate operation there were seven deaths (mortality 20.5 per cent), and after delayed operation seventeen deaths (mortality 8.7 per cent).

CONCLUSION

A survey of the literature shows that very few surgeons consider acute cholecystitis a condition requiring immediate surgical intervention as in the case of appendicitis. The conservative type of treatment, with operation after an interval of several days, has been followed in this series of cases. From our analysis of this series it would seem that a delay of several days is of advantage since it gives an opportunity to improve the patient's general condition without spread of the local process.

amateur regulators of human affairs began to appear on the scene ignorant amateurs who had never even "anatomized a malefactor", and yet who competed in the spiritual and physical management of souls in a manner thoroughly distasteful to competent professionals like William Pynchon. It became necessary to put a stop to such goings on. The manner in which medical licensure originated also, was delightfully simple. Mistress Hawkins was said to have a knack at practical obstetrics and to be a good hand at the prescription of medicinal herbs. Unhappily for her, however, she was caught at these practices by someone who did not approve. There was no Board of Registration in Medicine and no Committee on Ethics and Discipline to contend with, all that was required to put a stop to her activities was a General Court ruling, easily obtainable, no doubt, if one knew the ropes, "Jane Hawkins, the wife of Richard Hawkins, had liberty till the beginning of the 3rd month, called May, and the Magistrates (if shee did not depart before) to dispose of her, and in the meane time shee is not to meddle in surgery or physick, drinks, plaisters or oyles, nor to question matters of religion, except with the elders for satisfaction." These restrictions not proving sufficient, 'twas ordered some months later "Jane Hawkins is enjoined to depart away to morrow morning, and not to return againe hither upon paine of severe whipping and such other punishment as the courte shall think meete, and her sonnes stand bound in 20 pounds to carry her away, according to order." And that was that!

In cow-path days Springfield was far removed from Boston, an isolated community in the middle of Massachusetts the transportation problem was unsettled, there were no good roads, and there were plenty of Indians and other dangers to catch the unwary. Such being the case, there was little traveling so that each individual town in the Commonwealth was thoroughly independent and ran its own affairs in a manner to suit itself. It took no time at all for people to recognize that epidemics were uncomfortable, with high mortality, and that good health was almost a public necessity. One might argue, as did the Reverend Michael Wigglesworth of Malden, that the country was going to the dogs, that young people were not so good as they should be and that ill-health on the whole was more due to depravity than anything else.

*"Our healthful days are at an end,
And sicknesses come on
From yeer to yeer, becaus our hearts
Away from God are gone
New England, where for many yeers
You scarcely heard a cough,
And where Physicians had no work,
Now finds them work enough

*Massachusetts Historical Society Publications 12: 83 1871-1873

Now colds and coughs, Rheums, and sore-throats,
Do more & more abound
Now Agues sore & Feavers strong
In every place are found
How many houses have we seen
Last Autumn, and this spring,
Wherein the healthful were too few
To help the languishing

One wave another followeth,
And one disease begins
Before another cease, becaus
We turn not from our sins
We stopp our ear against reproof,
And hearken not to God
God stops his ear against our prayer,
And takes not off his rod

Beware, O sinful Land, beware,
And do not think it strange
That sorer Judgements are at hand,
Unless thou quickly change
Or God, or thou, must quickly change,
Or else thou art undone
Wrath cannot cease, if sin remain,
Where judgement is begun"

People less sentimental and more practical, however, believed that while prayer no doubt was useful yet the best way to control the spread of infectious disease was by more active methods. Boston's first quarantine law passed in 1647, marks the beginning of health control by municipal, state or federal agencies.

"For as much as this Corte is credibly informed that ye plague, or like grieves infectious disease, hath lately exceedingly raged in ye Barbadoes, Christophers, and other islands in ye West Indies, to ye great depopulating of those, it is therefore ordered, that all (our own) or other vessels coming from any pts of ye West Indies to Boston Harbor shall stop (and come to an) anchor before they come at ye Castle, under ye poenalty of 100 pounds, and that no persn coming in any vessel from the West Indies shall go ashore in any towne, village or farme, or come within foure rods of any other person, but such as belongs to the vessels company that hee or shee came in, or any wayes land or convey any goods brought in any such vessels to any towne, village, or farme, aforesaid, or any other place within this iurisdiction, except it be upon some island where no inhabitant resides, without licence from ye councill or some three of them, under ye aforesaid poenalty of a hundred pounds for every offence"

The early years of the eighteenth century added two more episodes significant to my narrative. In 1721, Zabdiel Boylston aided and abetted by the Reverend Cotton Mather introduced public education of the layman on medical affairs, thus laying the foundation for all the Sunday afternoon public lectures and for the popular books on health and hygiene that were to come later. In that year there was an epidemic of smallpox in Boston. Boylston having conducted a careful clinical investigation dealing with the mitigation of this disease by the method of inoculation published the results of his studies. This publication stirred up a great controversy people raved, ranted and blasphemed over it. But nevertheless as a result of

Boylston's efforts the mortality from smallpox dropped from around fourteen to a little over one per cent, and he demonstrated convincingly enough that doctors could be influential in the creation of medical propaganda and could deal effectually with masses of people through the medium of literature and public teaching.

Two years later some wise clinician pointed out that the rum drinkers of New England were

suffering inordinately from the "Dry Gripes" and that the cause of this unpleasantness lay in the fact that their rum was being distilled through leaden pipes. Accordingly the General Court ordered

"Whereas the strong liquors and spirits that are distilled through leaden pipes are judged on good grounds to be unwholesome and hurtful notwithstanding which some persons to save

charge may be led into the making or using of such heads worms or pipes for remedy and prevention whereof—

Be it enacted by the Lieutenant-Governor Council and Representatives in General Court assembled and by the authority of the same,

(Sect. 1) That no person whatsoever shall make use of any such leaden heads or worms for the future and that whosoever shall presume to distill or draw off any spirits or strong liquors thro such leaden heads or worms upon legal conviction thereof before any of his majestie a courts of record shall forfeit and pay a fine of one hundred pounds.

And he it further enacted by the authority aforesaid

(Sect. 2) That no braxier pewterer or other artificer whatsoever shall presume to make any worm or head for distilling of coarse and base pewter or such as hath any mixture of lead in it, under the penalty of one hundred pounds

This was the first time that governmental authority took steps to prevent any other disease than that of an infectious or contagious nature. Before 1775, therefore, medicine had advanced far beyond cow path days and the State already was exerting its influence.

Surely the War of the Revolution taught New England physicians two important lessons that there was an obvious dearth of men properly qualified by education to undertake the practice of medicine in spite of the old fashioned preceptor system, and that hospitals were the proper places for practical clinical teaching. After the War therefore medical schools and hospitals soon began to crop up in appropriate centers: Harvard (1782), Dartmouth (1798), Yale (1814), Brown (1814), Castleton Medical College (1820), Bowdoin Medical College (1821), University of Vermont Medical Department (1823), Berkshire Medical College (1823), Vermont Medical College of Woodstock (1830). The Massachusetts General Hospital opened in 1821,* at once becoming, as Sir William Osler was later to characterize a good hospital, "a place of refuge for the sick poor of the city, a place where students are taught the best in medicine, a place where new thought is materialized in research and a consulting centre for the whole country in cases of obscurity."

A very interesting curve can be constructed from the available figures of the Massachusetts Medical Society and the Massachusetts census. Apparently there has been a surprisingly constant relationship for nearly a hundred and fifty years between the size of our Society and the population of the Commonwealth. With the in-

There well may be a numerical relationship between the concentration of population and the need for hospital facilities. It is a striking coincidence that in 1410 when the Massachusetts General Hospital was being planned the population of Boston was 31,737 and that in 1884 when the Portland Hospital was being planned the population of Portland was 23,319. In 1921 Massachusetts has a population of about four and a half million there are 7 hospitals recognized by the American Medical Association or one hospital for each 17,000 people.

creasing needs for doctors in the early days, and the difficulties of transportation between the various towns, it is evident that medical schools like those at Pittsfield and Woodstock, to men-

to meet the demands for well-trained practitioners

Changes were due to occur In 1840, Springfield was eighty-seven miles from Boston and

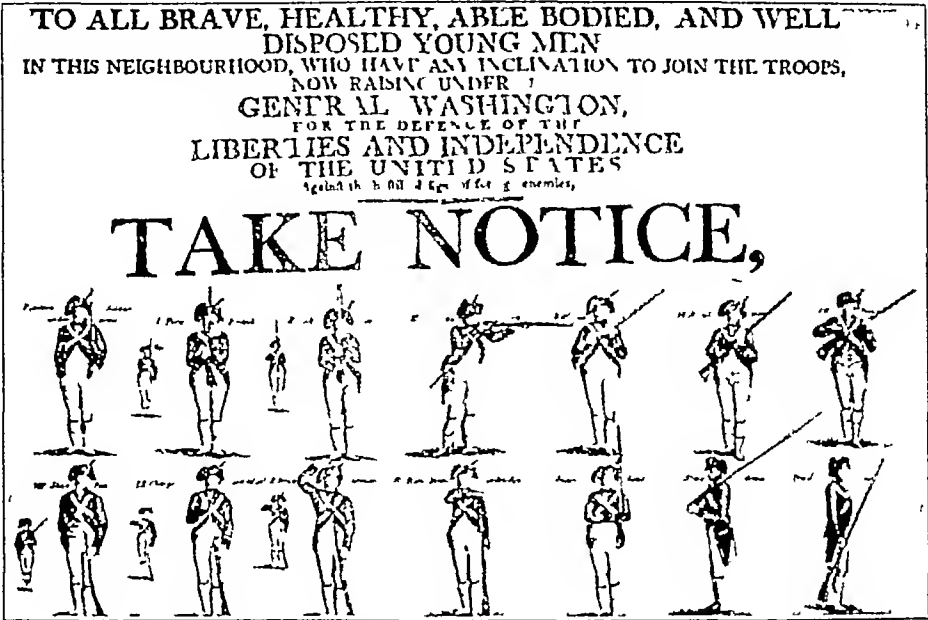

FIG 4 1775 1790 The Revolutionary Period An appeal for volunteers by General Washington There were almost no doctors to answer this call (Pennsylvania Historical Society Library)

FIG 5 • 1790 1935 The Growth of the Massachusetts Medical Society and the Population of Massachusetts

tion two of the more ephemeral ones, did an excellent and essential piece of work in helping

*Unfortunately this diagram does not tell the whole story In 1933 there were 4406 active members of the Massachusetts Medical Society and yet there were 7014 doctors listed as of Massachusetts by the American Medical Directory In that year 269 new doctors were licensed to practice in Massachusetts of whom 53 (20 per cent) were graduates of medical schools unrecognized by the Society In recent years the number of doctors with unrecognizable medical education who have migrated to Massachusetts has steadily increased The citizens of the Commonwealth cannot be guaranteed adequate medical supervision until they regain the courage of their Puritan forebears and handle medical licensure in as forceful a manner

sixteen hours away It was a homelike village of eleven thousand souls, with "two banks, several printing offices, six churches and many elegant private residences" To get there a Bostonian stepped aboard the mail stage at Earl's, 36 Hanover Street, at two o'clock in the morning, drove leisurely over the turnpike through Waltham, Sudbury, Marlborough, Worcester, Brookfield, Palmer and arrived in Springfield at six o'clock in the evening

Only a few years later railroads were to be built, opening up new country very quickly and shortening distances between old places even more remarkably Almost overnight, it seemed, Boston and Springfield were close neighbors, now only three and a half hours apart Such increased facilities for transportation had at once, I believe, a significant effect on medical education and progress The Commonwealth grew richer rapidly, and many boys heretofore unable to afford a college education could now obtain one The smaller medical schools were no longer necessary for it was nearly as easy for a Springfield student, for example, to go to the Harvard Medical School as it had been for his brother a few years earlier to go to Pittsfield People soon realized that large medical centres like Boston afforded better opportunities for medical institutions than the smaller towns

*Historical Collections John Warner Barber Worcester

FIG. 6 13 Th. F. Pike Boston to Springfield (Harvard Medical School Library)

Hence the smaller medical schools having filled a useful purpose before the railroads came now were gradually snuffed out the larger ones continuing to exist in accordance with the law of survival of the fittest.

The year 1850 is important to the tale I am trying to unfold for, in this year Mr. Lemuel Shattuck published his famous monograph 'Report of a General Plan for the Promotion of Public and Personal Health.' This remarkable

document, assisted by the Massachusetts Medical Society* as obstetrician eventually brought forth the State Board of Health.

It should be emphasized that Lemuel Shattuck was not a medical man but a school teacher, bookseller and publisher. He wrote his report with practically no assistance and from an extraordinarily farsighted point of view. He be-

In 1861 the Massachusetts Medical Society petitioned the Legislature for the establishment of a State Board of Health a petition which finally was heeded eight years later.

lieved, as others had believed before him, that public good health was an essential attribute to civilized living and was public property. There was a vast amount of unnecessarily impaired health that could be prevented the prevention of disease, on the whole, was much more important than its cure. He proposed that the State should enter the practice of preventive medicine in so far as this was possible by studying public health through accurately maintained vital statistics, by establishing and enforcing rational public health laws, by investigation of public health problems as they arose, and by continued improvement of public health by carefully controlled research. He advocated such modern projects as the medical inspection of school children, the development of training schools for nurses, the periodic health examination of apparently healthy people in fact he was far ahead of his time in many ways. Like so many pioneer efforts in medicine, the importance of his work at the time was largely overlooked, bearing fruit, however, many years later.

It is curious how slight an impression was made on medicine by the Civil War. Army surgeons were busy enough to be sure, and well organized modern-looking army hospitals were established. But no new medical knowledge came into existence during this period. The Civil War, however, brought forth one baffling thought that many doctors subsequently have pondered over. In concluding his Gettysburg speech President Lincoln said, "Government of the people, by the people, and for the people, shall not perish from this earth." How can this phrase best be construed in terms of medical pol

FIG 9 1864 The Civil War Mount Pleasant Hospital Washington D C a typical war Hospital (Harvard Medical School Library)

loy? Shall medicine becoming, as it has year by year, increasingly complex in its social and economic relations, best be regulated for the people, by the people through governmental control? Or will medicine in future be developed most safely, by the people, and for the people, through their insistence on a better trained more efficient profession managing its own affairs and operating for their benefit in a manner unhampered by overzealous legislative restrictions?

After the Civil War ended Massachusetts continued to grow. Between 1880 and 1900 three new complications to life were introduced

portance, and singularly well fitted to terrorize horses, was to become a universal means of transportation. In the fullness of time the motor car was to do to the railroad what the railroad had done to the stagecoach—it was to wipe out distance and timetables. Inaccessible places were to exist no longer and all Massachusetts doctors were to be within easy driving range of one another.

In the meantime before all this happened, the youthful State Board of Health was maturing. All over Massachusetts were developed improved conditions for maintaining good public health—better food, water and sewage control,

FIG. 10. 1890-1895. The Gay Nineties: The horseless carriage seemed a foolish means of transportation, of little practical use and singularly well fitted to terrorize horses. (Brookline Public Library)

Thomas Edison devised the electric light, Alexander Bell the telephone, and electrically driven horseless carriages began to appear on the roads. One could write an entertaining essay upon the effect on medicine of these three inventions. To be sure, knowledge regarding electricity had been developing gradually for a long time. But the invention of the telephone with dramatic suddenness shortened distance even more notably than had the railroads. Springfield and Boston were now within easy speaking distance instead of three and a half hours apart.

The electric light, by the interest it at once aroused in scientific minds, opened up a new pathway to increased medical knowledge. New physiological equipment with modern electrical devices soon developed and made possible new researches, and new clinical apparatus like the X-ray, the electrocardiograph and the basal metabolism machine presently came into existence and general use, each dependent upon advancing knowledge of how to use electricity to good advantage.

The horseless carriage, at first regarded as a freakish toy for the rich, of little practical im-

portance, and singularly well fitted to terrorize horses, was to become a universal means of transportation. In the fullness of time the motor car was to do to the railroad what the railroad had done to the stagecoach—it was to wipe out distance and timetables. Inaccessible places were to exist no longer and all Massachusetts doctors were to be within easy driving range of one another.

portance, and singularly well fitted to terrorize horses, was to become a universal means of transportation. In the fullness of time the motor car was to do to the railroad what the railroad had done to the stagecoach—it was to wipe out distance and timetables. Inaccessible places were to exist no longer and all Massachusetts doctors were to be within easy driving range of one another.

The Spanish War proved an important event to Massachusetts doctors because it focused public attention on typhoid fever. In 1895, three years previously, when clinical bacteriology came to light, the State entered the practice of therapeutic medicine by manufacturing and giving away diphtheria antitoxin. No one objected to this kind of lifesaving State medicine. A little later, when it became known that nearly one out of every five soldiers who enlisted for the Spanish War developed typhoid there was no notable objection to the suppression of this disease by the State. People now were being informed that various other infectious diseases might be prevented or cured by modern methods. Hence as the State increased its work no one rebelled. Smallpox vaccine was freely distributed, gonorrheal ophthalmia was attacked in a laboratory was established for the early diagnosis of tuberculosis, State made antitetanic and antimeningococcal sera were soon available. This chapter in the medical history of Massa-

chusetts is extremely interesting to think about, for it seemed to depend so definitely on three factors. A man at the head of the State Board of Health (the title of which was later changed to the State Department of Health) was essential with vision and courage enough to combat the problems at hand. This man was Henry P. Walcott, a former President of the Massachusetts Medical Society. An event was necessary

FIG. 11. 1898. The Spanish War. Visitors to Camp. One out of every five men in the Camp developed Typhoid Fever (Brookline Public Library.)

to excite the people over the unnecessary loss of human life from preventable infection and thus arouse a public opinion favorable to action. This event was the Spanish War. A scientifically trained man with sufficient expert knowledge to develop the State Laboratory Department satisfactorily and critically had to be found. This man was Theobald Smith. The combination of these three factors was largely responsible for the rapid development in State Medicine which has just been mentioned.

The years passed quickly and soon 1917 was reached. A new war was in the offing and was to teach Massachusetts doctors a new lesson. The War of the Revolution had revealed that there were not enough doctors to care for the needs of the rapidly growing population and that hospitals were the proper places for the best conduct of practical clinical teaching. The Great War demonstrated that there were not enough well-trained doctors to care for the

needs of the population and that properly organized hospitals afforded excellent opportunities for well-directed postgraduate instruction. Many doctors in practice but a little out of step with what was going on were to enter the Army Medical Corps and receive intensive postgraduate teaching by well-qualified instructors.

Many doctors were to learn in the army good medical organization, the relation of modern laboratory methods to diagnosis and treatment, the value of systematic history taking and physical examination, the difference between haphazard and skilled medical or surgical therapy. A certain number of doctors were to return from the army to civilian life, wondering whether it might not be possible to conduct civilian medicine on a military-like basis, with a properly organized profession under able leadership working as a unit to bring to the sick and wounded of the community all that is best in advancing knowledge.

The last few years, in the light of the trend that has been developed in the past, are especially noteworthy. For the period since 1920, at a time when American life was very complex, has demonstrated the effect on medicine of an era of too great prosperity. We still are so close to these years that it is impossible to evaluate them properly. Certain facts, however, are apparent which afford an interesting field for speculation.

To my mind three of the most striking features of the last few years have been the general realization of how important a profession medicine is, how intimately its development and that of American industrial life appear to be correlated, and how much simpler it is for the State to finance medicine than for charitable members of the community to do so.

The various statistical tables which have been published demonstrate that the wealth of the country increased in notable fashion between 1920 and 1930, and that the high tide of prosperity was immediately followed by an equally impressive ebb. Statistical tables dealing with medical affairs reveal a similar rise and fall. This can easily be demonstrated by comparing, for instance, the income of the country, the income of almost any large Massachusetts hospital, and the income from advertising paid to the *Journal of the American Medical Association* during this period. The resultant curves are strikingly parallel.

It is a reasonable conclusion that from 1920 to 1930, when the country's income was becoming larger and larger, medicine, like other industries, overexpanded. In those days, evidently, it paid to advertise. New and expensively built hospital plants were established, old hospitals were made over, new laboratories were built, new and expensive hospital equipment was manufactured and sold, new and expensive

drugs became popular, new books were written and found a market, the cost of good medical care was exaggerated. When depression came after the stock market crash in 1929 there was no longer money available to carry on the great

A few pioneer medical economists began to express their ideas and warnings during the era of prosperity when hospitals and doctors suddenly became poor there was a sharp almost hectic rise of interest in medical economics which

FIG. 1. 1913. The General Hospital, Harvard Medical School Library.

overhead expense that had been set up. The question arose as to what should be done.

The immediate effect of such a situation has been to bring into existence a new field of medical literature. A few years ago the sub-

FIG. 1. 1913. The relation between the income of the United States of a typical Massachusetts Hospital and of the Journal of the American Medical Association from advertising.

ject of medical economics was rarely discussed, now it is a favorite topic. The growth of this type of reading matter as reported in the Quarterly Cumulative Index presents a curve almost inverse to the curves of hospital income and medical advertising.

FIG. 14. 1913. The development of a new medical literature.

persists. It is only comparatively recently that various plans for hospital or health insurance have been widely debated and are receiving seri-

ous consideration and that community chests have become a common method for attempting to keep alive medical interests that otherwise might die

FIG 15 1920 1934 The growth in annual appropriation and certain activities of the Massachusetts State Department of Health

The State, on the other hand, has continued its medical work untrammelled. Regardless of depression or prosperity, money has been forthcoming to make sure that good public health should be maintained in Massachusetts, so far new funds have always been found to carry forward such new projects as our Department of Health has considered advisable.

Fortunately no historian is expected to do more than study the past; it is not his function to attempt to forecast the future. As one reviews, even casually, the three hundred years of medicine that have elapsed since Springfield was founded, it is difficult to avoid one definite conclusion. In 1855, the Massachusetts Medical Society met here for the first time. The members from Boston who drove to the meeting rose early for their unhurried journey over the turnpike through Waltham, Sudbury, Marlborough, Worcester, Brookfield and Palmer. Today, I will wager, the members from Boston who drive homeward from Springfield after their third meeting here, will be conscious of one very significant impression which never before has been so inescapable. As they speed past green, red and yellow lights on the new highway, they must realize, perhaps somewhat sadly, that the old independent days of cow-path and turnpike are gone. Now, with the rest of the citizens of Massachusetts, they are traveling, on occasion too fast for safety, along the State Road.

FIG 16 1936 The State Road Boston to Springfield

THE HEREDITARY ASPECT OF PROGRESSIVE
PSEUDOHYPERTROPHIC MUSCULAR DYSTROPHY

BY GARRY DEN HOUGH, JR., M.D.*

IN a recent contribution on the inheritance of muscular dystrophy Karl Pearson¹ said "There are few pathological states productive of greater human misery than the muscular dystrophies. There are hardly any states which have a more marked familial character and none wherein it is more the bounden duty of the unaffected members of a tainted stock to refrain from reproduction." He further asks "Are we to wait till these muscular dystrophies have been classified into separate categories and an adequate series of pedigrees collected for each type?"

In my opinion, such classification and collection of pedigrees is exactly what is needed and for that reason I am reporting the following family history. This family represents the only instance in my personal investigation of over a hundred cases of the pseudohypertrophic form of muscular dystrophy in which the condition was known to be present in more than one generation although frequently two or more cases in siblings have been observed. As will be seen the transmission was through the apparently normal female members of the family.

In the H. Family which I am presenting a single child (IV 19 on the chart) first came to my attention. At that time he was twelve years old and presented an advanced stage of typical pseudohypertrophic progressive muscular dystrophy of the usual Duchenne type. In obtaining the family history it was found that two first cousins (IV 15 and 16) were suffering from the same disease. Further investigation discovered two more cases in second cousins (IV 1 and 2).

Through the interest and co-operation of the family information was obtained concerning seventy nine other members of the family. The brother of the maternal great-grandmother (I 3) was a cripple and was "always confined to a wheel chair. He died between thirty and forty years of age. The cause of death could not be ascertained nor could any information be obtained concerning any progression of his disability. While by no means certain it is possible that he represents a case of progressive muscular dystrophy.

The apparently healthy sister of this cripple married and had eleven apparently normal children: five boys and six girls. She died at eighty-four years of age and her husband at eighty-nine. Four members of the second generation are no longer living. One died of cancer, one died aged forty-five years of unknown cause, one died at eighteen of tuberculosis and one died of typhoid at eight years. Eight siblings, three males and five females, had offspring the known families varying from two to thirteen.

The third generation consists of forty-six known individuals: twenty males, eighteen females and eight whose sex is not known. Thirty-six of this generation are now living and ten have died. Five sib-

lings in one family died of tuberculosis and three in another family died at birth. One died in child birth and one was drowned. There is no individual in this generation with any suggestion of muscular dystrophy.

The known individuals of the fourth generation which includes the five cases of dystrophy consist of nine males and ten females, the offspring of seven members of the third generation who were the children of the ninth and tenth in the series born in 1867 and 1870 respectively. Five of these were females and two males.

The five children of the two males are all normal while five of the fourteen children of the five females show the disease. Two of the children are only two years old so they may possibly still develop the disease but at present they show no evidence of it.

It is unfortunate that information could not be obtained concerning the offspring of the earlier part of the third generation but this was impossible.

LITERATURE

As early as 1862 and again in 1869 Duchenne presented two brief pedigrees of families in which muscular dystrophy of the facioscapulo-humeral type was transmitted as a mendelian dominant. These are quoted by Pearson¹ who presents two more family histories: one of the facioscapulo-humeral type and one of the pseudohypertrophic form. In the first, the transmission was direct through the affected individuals for four generations.

Barker² in 1930 called attention to the fact that the hereditary transmission of the disease was a reliable method of differentiating certain types of progressive muscular dystrophy. He pointed out that the facioscapulo-humeral type, to which the name of Landouzy Dejerine has been applied, is commonly transmitted as a mendelian dominant. The more frequent Duchenne type in which the involvement with pseudohypertrophy first appears in the lower extremities Barker stated, was usually a recessive characteristic.

Minkowski and Sidler³ in 1927 first called attention to the factor of parental consanguinity. They studied a series of cases of the disease occurring in an isolated village in Switzerland where genealogical data were available over a period of 300 years. They found that all afflicted individuals were descendants of two families (R and H) among whom there had been many intermarriages. Progressive pseudohypertrophic muscular dystrophy appeared only when both father and mother were descended from both the R and H family and the transmission was not sex linked. In this connection it may be noted that a high incidence of the disease has been observed among the French

*Hon. Garry Den, Jr.—Assistant Surgeon Shriners' Hospital for Crippled Children. For record and address of author see "This Week's Issue" page 104.

Arcadians in Louisiana.* It is suggested that the intermarriage of similarly related families might be found among these people who have maintained their traditions and identity over a considerable period.

A third type of family history has been presented in recent studies in which the transmission has followed the same course as in hemophilia. The unaffected daughter in these families transmits the disease to her son.

Dittich⁴ of Heidelberg has reported such a family history in which six cases have occurred in three generations. The transmission was twice through an apparently healthy oldest daughter and once through an apparently normal second daughter.

Voshell⁵ of Baltimore has contributed a most interesting family history of ten cases occurring in four generations. He presents data concerning seventy-five descendants and in every case transmission was by the unaffected female.

In a recent contribution Kostakow⁶ reports a family history of forty-nine individuals in four generations, fifteen of whom presented dystrophy. In this family, also, the inheritance was purely as a sex-bound recessive appearing in the male children of apparently normal females. He cites references in the literature to this type of transmission (Bing⁷), and also as both a dominant (Weitz,⁸ Riese,⁹ Davidenkoff¹⁰ and Barnes¹¹) and as a recessive (Weitz⁸).

SUMMARY

The pedigrees of families showing progressive muscular dystrophy in the literature show that the hereditary transmission may be as a dominant, a recessive, or a sex-linked characteristic.

A family history presenting six cases of the disease, one of which is uncertain, is here reported. Seventy-nine known individuals are recorded. The transmission was in all cases in this family through an apparently normal female.

CONCLUSIONS

1. There is increasing evidence to substantiate Barker's statement that the facioscapulo-humeral or Landouzy-Déjerine type of progressive muscular dystrophy is transmitted as a dominant characteristic. As these individuals frequently live to sexual maturity, they should be warned against having offspring.

2. The more common pseudohypertrophic or Duchenne type of progressive muscular dystrophy is apparently transmitted through the clinically normal female members of the family, exactly as is hemophilia. Perhaps this is due to the fact that individuals with this type of the disease are almost always incapacitated.

*Personal communication from Dr. Francis L. Fort, 1042 Park Street, Jacksonville, Florida.

before sexual maturity. There is sufficient evidence to prohibit reproduction by the apparently normal females in such a family, but to permit offspring to the apparently normal males.

3. The method of inheritance may be used as a basis of sound classification as it is directly concerned with the prevention of the condition. This is important because one source of confusion in recent studies has been the inclusion of all cases presenting the syndrome of muscular dystrophy in one clinical group. This has been due to an effort to simplify our consideration of the condition and is based on the recognition that the original classifications founded on anatomical localization and the presence or absence of pseudohypertrophy failed to serve any useful purpose. However the varying types of hereditary transmission as well as other evidence seems to prove conclusively that these cases are not all one disease entity.

MYXEDEMA FOLLOWING THE REMOVAL OF AN
ABERRANT THYROID TUMOR*

BY J. G. PROBSTEN, M.D.† AND HARRY AGRESS, M.D.‡

It is extremely interesting that profound disturbances in thyroid metabolism such as myxedema, are frequently attendant upon the removal of median aberrant thyroid tissue. This phenomenon is strikingly in contrast with the extirpation of lateral aberrant thyroids. The discrepancy is best explained by differences in embryonic development. There is general concurrence of opinion that the pathogenesis of median aberrant thyroids is that of an arrested descent of the tissue along the thyroglossal duct tract from its origin at the thyroid tubercle to its ultimate resting place in the normal organism. That myxedema follows the removal of such thyroid tissue is readily appreciated since it might well be the only thyroid present.

On the other hand, there is no such agreement concerning the pathogenesis of lateral cervical aberrant thyroids. It has been conjectured that one or possibly a combination of three probabilities account for these moot elements, namely (a) variations in the development and descent of the ultimobranchial bodies or "lateral anlagen" as inferred from the observations of Kingsbury¹ and of Norris;² (b) migratory propensities of human thyroid tissue similar to that noted in salmonid fishes by Gaylord and Marsh;³ or (c) the separation of nodules from the parent thyroid observed in endemic goiter regions by Rendin Stern and Beerholdt. (Quoted by Moritz and Bayless⁴)

Cattell⁵ reports a patient in whom mild symptoms of myxedema with a normal basal metabolic rate existed preoperatively and in whom mild hypothyroidism developed following the removal of a lateral aberrant thyroid tumor. Myxedema in such instances is unique and prompts the report of this case of total hypothyroidism following the extirpation of an unusually located cervical tumor mass.

CASE REPORT

S. D., a seventeen year old white female appeared on July 13 1933 at the Out Patient Department of the Jewish Hospital complaining of a swelling which had been present for two weeks just to the right of the midline in the sublingual region. Her past history was interesting in that it was one of retarded development in infancy and early childhood. Her first teeth appeared at the age of two years and she did not start to walk or talk until four years of age. She was always somewhat mentally retarded as compared with other children in the family. Her menses started at the age of seventeen years, were irregular scanty and painful.

At the time she first presented herself her physical examination was essentially negative except for the presence of a small painless swelling in the right sublingual region. Further observation and consultation were deemed advisable and when she was seen again in several weeks there was no change noted in the nature of the mass. The roentgenologist reported "a suspicious bony projection probably stone in the sublingual region." Unfortunately a basal metabolism was not taken before operation.

Exploratory operation was advised with the following clinical diagnoses: (a) Sublingual lymph gland; (b) "suspected obstruction of the sublingual ducts"; (c) hygroma; and (d) "thyroglossal duct cyst."

Operation was performed under gas-ether anesthesia August 9 1933. A spherical soft tumor mass approximately 3 cm in diameter was found superior

*Personal communication from Dr. Francis L. Fort, 1022 Park Street, Jacksonville, Florida.

of a lingual thyroid (and we might add, any suspected median thyroid) does not necessarily indicate active treatment" was not well taken in this instance. He urges that routine cervical exploratory operation for thyroid tissue in the normal position be performed before removal of an aberrant thyroid or any tumor in the neck which may always be thyroid tissue. On the other hand, the known "tendency (of lateral aberrant thyroids) toward a specific type of tumor formation" and the malignant tendencies of this tumor^{2, 5, 9, 15} indicate complete removal. This is particularly desirable in view of the excellent postoperative prognosis offered.^{6, 9, 10} Although malignant changes in median tumors have been reported^{1, 2} their incidence is extremely rare, most of the median tumors being simple colloid goiters or normal thyroid tissue. The fact that our case was one of benign papillary cystadenoma would favor its classification among the lateral cervical group.

Myxedema is unique following the removal of lateral tumors. This fact alone leads us to place our case in the median group. Another fact in favor of this classification is the presence of a single mass, multiplicity^{9, 14} being the more common occurrence in the lateral group and even bilateral involvement being conjectured.¹⁴

SUMMARY

A girl, aged seventeen years developed complete myxedema following the removal of a

right suprahyoid aberrant thyroid, which was apparently the only thyroid tissue present. Her recovery was complete following replacement therapy.

MEDICAL PROGRESS

RECENT PROGRESS IN PHYSIOLOGY

BY PERCY O. STILES, PH.D.*

VASOMOTOR Reactions of the Mucosa. A question long discussed in this connection has been reopened and fully examined by Spiesman.¹ The traditional teaching has been that a reciprocal relation is maintained between the vascular condition of the skin and that of the nasal and pharyngeal lining. According to this view the contraction of the surface vessels when the skin is chilled induces an engorgement of the mucous membranes. The resulting congestion has been held to have much to do with the "catching" of colds. The suggestion has been entertained that the primary active congestion becomes passive and that the resistance of the tissue to bacterial infection is lowered in consequence. Twenty years or more ago evidence was presented to show that the reaction of the respiratory membranes to cooling of the skin is quite opposed to what has been pictured. The

observations of Spiesman support this conclusion that the vasomotor changes in skin and mucosa are not contrasted but parallel.

The means employed to discover the behavior of the vessels consists in a thermal couple so secured as to keep a steady contact with the nasal lining. Cold applications are made on various parts of the body surface. It is found consistently that when a patch of skin is cooled the mucous membrane registers a shift in temperature in the same direction and not upward as would formerly have been predicted. Having fallen to a minimum the temperature of the nasal lining gradually returns toward the initial reading but almost always stops short of it showing a lasting effect of the cutaneous cold. It can be lowered again by transferring the cooling to a different area.

Tests have been made from day to day on several subjects who have from time to time developed colds. It appears that the vascular

*Stiles, Percy O.—Assistant Professor of Physiology in the Medical School. For record and address of author see "This Week's Journal" page 1201.

reactions of the mucosa become modified when the symptoms of a cold are manifest. The assumption is made that colds may be either sterile or bacterial, the first being essentially an exaggerated vasomotor disturbance and the second founded on a bacterial or virus infection. Undertaking to distinguish the two in his volunteers Spiesman reports that the simple vasomotor rhinitis is a condition which features the traditional internal engorgement under the influence of external chilling. The more toxic type of cold does not show this reversal of the normal reflex constriction but the readjustment is said to be delayed. The impression is left with the reader that vasomotor changes are not so definitely the cause of colds as they are superficial signs of a change taking place in the tissues.

It has been shown that the sensory nerves concerned in the reaction to external cold are those of temperature rather than those of pain. Intense local cold is definitely painful but the noxious component can be suppressed by subcutaneous injection of butyn epinephrine solution. The responses to cooling of the analgesic area continue unaltered. The heating of a portion of the skin can be demonstrated to increase the blood-flow and hence the temperature of the respiratory membranes.

Reflexes from the Skin as Affecting Skeletal Muscle Tonus. This matter readily linked with the last, has been dealt with by workers in the Yale Medical School.² It has long been taught that the depressing effect of stagnant air may be due in large part to the failure of such air to maintain the desirable type of stimulation of cutaneous end-organs to which we are accustomed. Mild air currents have been said to excite both the vasomotor effectors and the voluntary musculature. In default of this surface stimulation there is conceived to be a retarded return of blood to the heart. To an unfortunate extent it finds storage space at the periphery. Since the heart can obviously pass on only so much blood as it receives, the output to the arteries must be reduced and the tendency of the systemic pressure must be downward. These changes may well explain the drowsiness and the sense of inertia commonly associated with stuffy rooms.

The novel technique described in the paper here reviewed is offered as a means of estimating the varying tone of skeletal muscle. The value recorded is the pressure required to begin the intramuscular injection of sterile saline through a needle inserted into a selected muscle. The more complete the relaxation the more easily the inflow will be started. The effect of the general physical condition on muscle tonus may be judged from the following comparison. Two groups of ten each were examined, ten being in good health and ten patients confined to

then beds. With the normal subjects the average pressure in millimeters of water necessary to begin the injection was 74, for the invalids it was 47. It is pointed out that muscles so softened will harbor a great deal of blood and this is an important factor in prostration.

To determine the effect of air currents on the muscle tone this injection test was made upon naked men lying in a warm room where drafts could be created when desired by turning on an electric fan. The change was definite, the resistance of the muscles to the entrance of water was always increased, commonly by 15 or 20 millimeters of the scale. There was no corresponding increase in the arterial blood pressure. The reaction is found to be based on the mechanical stimulation of the draft rather than on any cooling of the skin.

Supplementary experiments have shown that bathing the skin with carbonated water has a reflex effect on muscle tone in the same direction as that of air currents. This is to say that the entrance of injected saline into the muscles is hindered and it is fair to assume that blood is displaced into the veins. So far as the reaction of the skin is concerned it is opposite for carbon dioxide to what it is for a draft. The gas produces a flushing of the body surface which is evidently the sign of peripheral dilation.

Compressed Air. In a previous review reference was made to the limiting pressure of oxygen which can be breathed with safety. Human subjects have lost consciousness when remaining for forty-five minutes under an oxygen pressure of four atmospheres. This is nearly twenty times the normal atmospheric pressure of oxygen since the percentage in air is just short of twenty-one. In studies of compressed gases it is necessary to make allowance for the presence or absence of nitrogen from the mixtures. A recent communication³ makes it possible to compare the effect of straight oxygen at four atmospheres (already indicated), with that of air having the same pressure. This air, such as might be sent to a diver 100 feet below sea-level, offers oxygen under a pressure of less than one atmosphere and nitrogen at more than three. It appears that nitrogen under such compression adds to the hazard of the situation.

Men remaining long in this compressed air have given evidence of mental confusion. The impairment of their powers of judgment and decision has been suggestive of the early stages of anesthesia. Since the oxygen pressure is far from being high enough to be responsible the rôle of the nitrogen calls for consideration. Among the physical properties of this gas there is noted its rather high solubility in bodies of the lipid group. Many if not all the volatile anesthetics are distinguished in the same way and their tendency to unite with fatty constituents of the nervous system has been invoked

to explain their narcotizing action. It is customary to speak of nitrogen as an inert gas but in this particular respect it may exert a definite pharmacological influence.

As nitrogen modifies the effect of compressed air during the period of inhalation so it figures in the risks of the subsequent decompression. The disturbances collectively called caisson sickness, compressed air illness, or 'bends' have long been referred to the formation of bubbles in the blood and elsewhere as the result of too rapid easing of the external pressure. Both oxygen and nitrogen may conceivably share in this effervescence. But oxygen has the better chance of disappearing promptly from the tissues since their metabolism calls for it. There is no corresponding possibility of getting rid of nitrogen; its removal must be by way of the lungs and of necessity a gradual process.

When an animal has been subjected to severe compression and a quick reduction of pressure has followed, a great variety of symptoms may appear. Many of these are explicable as due to obstruction of the pulmonary circulation by minute bubbles described as nitrogen emboli. A renewed application of pressure, using either pure oxygen or air, may relieve the situation. The significant fact has been noted that such relief is less likely to be succeeded by fresh embolic signs when oxygen is used than when compressed air is employed. It seems rational to charge the "iron doctor" with oxygen or at least to limit its nitrogen content to that measured by the partial pressure of this gas in the atmosphere.

The Cerebral Cortex and Heat Production
It has been shown that decorticate warm-blooded animals preserve some power of temperature regulation although the function is more or less impaired. It has remained until now to determine the effect of cortical lesions on the metabolic rate. The communication to be summarized is from Rakićen.¹ In the cerebrum of the monkey as in the human being motor and premotor areas are distinguished standing in relation to the tension and use of the skeletal muscles. These areas have been removed in variously modified experiments and the metabolism of the surviving animals has been measured on the basis of oxygen consumed and carbon dioxide liberated.

The excision of both motor and premotor areas on both sides has been followed by an increase in metabolism in proportion to surface area, amounting to from 15 to 30 per cent. The high level has been maintained for as long a period as seven weeks with no tendency to decline, therefore it can hardly be attributed to irritation. The nutrition of the monkeys has suffered in some degree but this would be expected to depress the metabolic rate. The rise is rather to be associated with the increased spasticity of

the musculature which is characteristic of the condition. The observation calls to mind the fact that a large share of the influences exerted by the cerebral centers are inhibitory in their nature. This has long been recognized as regards muscular activity and it might have been predicted that it would be paralleled in metabolism.

In fact a paper has just been published by Riech and Rosenblith² which reopens the subject of cortical inhibition as exercised upon the lower motor mechanisms. It will be recalled that there are comparatively few parts of the cortex stimulation which can be relied on to call forth muscular movements. When, however, movements variously caused are going on cortical excitation at numerous points will be found to check them. Furthermore it has been noted that stimulation of one hemisphere will often put a stop to muscular activity on either side of the body.

The Role of Nerves Having Slow Conduction

The fibers which are bound together in mixed nerves have lately been assigned to three classes usually designated as A, B and C. Those of the third type are the most slender; they are nearly or quite without myelin, and they are difficult to stimulate. In particular the impulses propagated along the C fibers are incredibly slow by all the standards of a few years ago; they may proceed at such rates as 1 meter per second. If all the fibers in a long nerve are stimulated at one end it will be clear that, as the impulses pass along, those in the fastest conducting (A) fibers will forge ahead and those in the C fibers will lag behind. Instruments are available to detect the flight of these disturbances as they pass selected points.

Using the techniques of electrophysiology Clark, Hughes and Gasser³ have been able to analyze the activities of the different fiber groups in nerves of the cat. Means have been devised for blocking conduction along some of these without interfering with it in others. Differential studies show that when only the C fibers are functioning in afferent nerves it remains possible to obtain vascular and respiratory reflexes. When a stretch of nerve is subjected to asphyxia the C fibers are found to be the latest to become blocked. They are still in condition to convey impulses after forty-five minutes suspension of circulation.

Comparing this finding with what is known of the properties of human nerves the inference is encouraged that the C fibers include those responsible for sensations of warmth and pain. This is in the light of the fact that only these sensations persist after such an interruption of blood supply to a limb as suppresses the A and B components in the cat.

The study of action potentials in nerves, the experimental method just referred to, is more

and more employed in analyzing the details of various reactions. A curious example is afforded by a case of stuttering.⁷ Galvanometric records were made from the two masseter muscles in the victim of the speech defect and from those of a normal subject. In the control there was a practical identity between the features registered on the right and on the left. In the patient the tracings were dissimilar, the faulty co-ordination found expression at the low level of the motor centers in the brain-stem. The curious question is raised of how high up among the superimposed levels of the nervous system the trouble may be supposed to originate. Does the thought of the unfortunate individual meet with the same interruptions which we find so painful in the halting vocal performance? In other words, are we to think of the cortex as stuttering or does it start well-ordered currents to the subcenters only to have them meet with derangement en route?

A large share of the current physiological literature pertains to vitamins, hormones and humoral agents. Obviously these have much in common and have ill-defined border lines. The part played by humoral compounds in the development of processes formerly charged to the direct action of nerves on their effectors is constantly discovered in new localities. A typical example may be mentioned. This is embodied in a paper by Bunting, Meek and Maaske.⁸ The subject is the chemical control of the small intestine through the vagus nerve and its hormone, a substance having many of the properties of acetylcholine and perhaps identical with it. Two methods were employed, the first

made use of an isolated intestinal loop which was under observation during vagus stimulation. The loop although no longer supplied with nerves was found to reproduce the motor activities of neighboring parts still subject to nervous control. This is good evidence of a humoral agent at work but does not indicate where it has been formed.

The additional information that the hormone is really to be obtained from the small intestine has been secured by perfusing the vessels of the gut and testing the power of the perfusate to inhibit the frog's heart. An effect could be produced which it was possible to reduplicate with acetylcholine in Ringer's solution. The inhibitory property was found to be characteristic of the perfusate returning from the small intestine even when the vagus was not stimulated but the degree of the effect was much increased by such stimulation.

ROCKY MOUNTAIN SPOTTED FEVER

According to the Department of Agriculture, three recent cases of Rocky Mountain spotted fever have been found near Washington, D C. This disease is widespread and has a high mortality. The wood tick is the vector largely responsible for the spread of the disease. Dr F C Bishopp of the United States Department of Agriculture has warned the public of the danger of the existing prevalence of these parasites here in the East especially in Maryland, Virginia, Delaware and North Carolina.

Spotted fever has been reported from many states in the Eastern part of the country, except in New England, Ohio, Michigan, Wisconsin and Mississippi.

These ticks attach themselves to dogs and other animals and hence may be transported to widely separated areas. In the far West a different species of ticks is responsible for spotted fever infection.

Further information with respect to the menace of ticks may be obtained on application to the United States Department of Agriculture.

A PLAN FOR CONDUCTING MENTAL TESTS

The report is current in the daily press that psychiatrists are to be employed by the Federal Gov-

ernment to examine the mental condition of defendants in Federal Court proceedings.

The list of psychiatrists appointed to serve the Massachusetts Federal Courts is as follows: Dr Joseph E Barrett, Assistant Commissioner of the State Department of Mental Diseases, Dr C MacFie Campbell, Medical Director, Boston Psychopathic Hospital, Dr Gerald F Houser, Assistant Superintendent of Boston State Hospital, Dr Frederick LeDrew, Senior Physician, Boston State Hospital, Dr E Houston Merritt, Jr, Boston City Hospital, Dr Winfred Overholser, Commissioner, Massachusetts Department of Mental Diseases, Dr Tracy J Putnam, Boston City Hospital, Dr Harry C Solomon and Dr Henry R Viets both of Boston.

Selections from these appointees will be employed when desired by the Court.

A NEW GENERATOR FOR X RAY THERAPY

A new form of high voltage generator for x ray outfits used in medical therapy, operating on radically new principles and with marked advantages and economy over previous types, has been invented and tested, and the first unit is being installed in the Huntington Memorial Hospital—*Science*, May 29, 1936.

CASE 22241

PRESENTATION OF CASE

A fifty-three-year-old native pointer was admitted complaining of weakness and hiccup.

Three years before entry the patient had an attack of right-sided pleurisy which caused him to remain at home, but not in bed, under medical care for nine months. His illness was associated with marked weakness, slight cough, but no fever or chills. During this time there was aching pain in the right shoulder arm and elbow with some numbness of the fingers. This was termed neuritis. Thereafter all symptoms subsided and the patient felt very well until three months before admission. At this time he noticed increasing weakness of his legs and arms with some numbness of the fingertips and slight dull headache. There was no fever, cough, or pain. There was slight dyspnea on exertion. Three weeks ago having been unemployed for some time, he succeeded in obtaining work. At this time he contracted a slight cough which persisted and was associated with some hoarseness. Seven days before entry upon his own initiative, he had six teeth extracted. He continued to work for three days afterward although he became very weak, felt dizzy and developed hiccup. The latter was continuous and, although he obtained some rest by means of soporifics, his wife stated that it continued during his sleep. His weight had decreased from 130 to 116 pounds during the preceding three months.

Physical examination showed a well-developed and nourished man hiccupping at frequent intervals. Many small telangiectases were noted on the nose and cheeks. The right pupil was slightly larger than the left but they both reacted normally. The right disc was slightly more blurred than the left. There was inconstant lateral and vertical nystagmus. With transillumination the right antrum appeared less translucent than the left. Small epitrochlear nodes were palpable bilaterally. There was dullness over the right lower chest anteriorly and posteriorly and in this region tactile fremitus and breath sounds exhibited diminished intensity. No rales were heard. The heart was normal. The blood pressure was 110/72. The prostate was slightly enlarged and boggy. No other de-

tails were noted. The upper and right lower abdominal reflexes were absent. The patient showed a wide based gait but the tendon reflexes were all normal and no abnormal reflexes were elicited.

The temperature was 99.4°, the pulse 70. The respirations were 20.

Examination of the urine was negative. The blood showed a red cell count of 4,150,000 with a hemoglobin of 75 per cent. The white cell count was 3,400, 88 per cent polymorphonuclears. The smear showed no stippling of the red blood cells. No tubercle bacilli were seen in a specimen of sputum was not obtainable. The stools were negative. A basal metabolic rate was -1. A Hinton test was negative. The serum calcium was 7.85 milligrams and the phosphorus 2.5. An intradermal injection of 1:20,000 tuberculin showed a 9 millimeter raised area without erythema. The serum protein was 5.5 and the cholesterol was 175 milligrams. Agglutination tests for undulant fever and the typhoid group were negative. A lumbar puncture showed an initial pressure of 40 mm. Dynamics were normal. A cell count showed one lymphocyte. The alcohol test was positive and the ammonium sulphate faintly positive. The total protein was 48 milligrams and the sugar 77 milligrams. A Wassermann test of the fluid was negative.

X-ray examination of the chest showed dullness at the right base obscuring the costophrenic angle and lateral portion of the diaphragm. There was considerable thickening of the axillary pleura. In the lateral view the dullness lay posteriorly. There was indefinite mottling in the left first interspace. Another film two days later showed mottling in both infracardiac regions. A film of the skull was negative as was a gastrointestinal series.

During his hospital stay the patient's temperature fluctuated between 98° and 101° and his pulse between 70 and 100. Further details elicited from his wife demonstrated the fact that he had showed drowsiness, slow slurred speech, and considerable headache during the preceding three months. Examination on the fourth hospital day showed the patient to be drowsy. His speech was slow and hesitant. The facies exhibited a mask-like quality. There was no nystagmus and the pupils and fundi were negative. Deep reflexes were symmetrically active. Both abdominal and the right cremasteric reflexes were absent. There was no Babinski sign. The patient walked on a wide base and deviated to the right with his eyes closed. In the Romberg position he fell to the right and backward. His course continued relatively unchanged. The hiccup ceased occasionally and there were infrequent attacks of vomiting. On the sixteenth hospital day a lumbar puncture showed an initial pressure of 270. A cell count showed three lymphocytes and one polymorpho-

nuclear cell. The total protein was 44 and the qualitative tests for globulin were unchanged. On the same day a ventricular puncture was performed. Clear fluid was withdrawn from the left ventricle without evidence of increased pressure. The right ventricle could not be entered. The patient exhibited bradypnea after this procedure and his blood pressure dropped to 50/20. He was treated supportively and two days later a ventriculogram showed filling of all the ventricles. There was slight dilatation of both anterior horns and the third ventricle but no definite displacement. He became comatose and died on the following day.

DIFFERENTIAL DIAGNOSIS

DR DONALD S KING. This patient had two sets of symptoms—pulmonary and neurologic. Let us take up the two pictures separately, first the respiratory picture, and secondly the cerebral picture. Three years ago for a period of nine months he is said to have suffered from pleurisy accompanied by weakness, cough, pain in the right shoulder, pain in the right elbow, and numbness of the fingers, but all these symptoms cleared and he was free from symptoms for two years. This story, I should say, is consistent with tuberculous pleurisy. The pain in the right shoulder could be accounted for on the basis of a diaphragmatic referal and I am inclined to discount the diagnosis of neuritis in the right arm. Three months before his admission to the hospital there were weakness and dyspnea and the start of a fourteen-pound loss in weight. Three weeks before admission cough and hoarseness began. The respiratory history is consistent with pulmonary tuberculosis which started with pleurisy followed two years later by a reactivation of a pulmonary process.

The physical signs are consistent with old tuberculous pleurisy at the right base. The temperature and pulse are those of an acute tuberculous process. If military tuberculosis were present it would probably not give any additional physical signs, so that the examination is consistent with old tuberculous pleurisy and acute military tuberculosis.

A tuberculin skin test was positive. There was a definite leukopenia and a high percentage of polymuclear neutrophils. These blood findings are consistent with military tuberculosis and are occasionally responsible for the confusion of this disease with typhoid fever. The blood chemistry shows a low total protein, a low serum calcium and phosphorus, and a normal cholesterol. So far as I know, this chemical picture has no especial diagnostic value and is consistent with military tuberculosis.

The x-ray film in my opinion, Dr Holmes, is consistent with tuberculous pleurisy at the right base and military tuberculosis at the apices. Do you agree with this diagnosis or do you feel that some other diagnosis is more likely or that

the changes which suggest military tuberculosis should be discounted?

DR GEORGE W HOLMES. My interpretation would be about the same. The amount of change is not so marked as one would expect with a full-blown military tuberculosis. It looks more like an old infection or a rapid form of tuberculosis rather than true military.

DR KING. We have only these two films. They are not far enough apart to tell whether the disease is progressing. I take it that the x-ray department does not believe this to be sarcoid, military carcinoma, military abscesses, fungus infection, and so forth.

DR HOLMES. No.

DR KING. The respiratory picture is then in my opinion consistent with old tuberculous pleurisy and military tuberculosis.

Now as to the neurologic picture. The "neuritis", which he had three years before I am throwing out. During the three months before the hospital admission there were drowsiness, slurred speech, headache, weakness of the arms and legs, and numbness of the fingertips. After admission to the hospital there was a continuous stupor going into coma, increased weakness, vertigo, hiccough and vomiting. If one has accepted the diagnosis of military tuberculosis, he would then naturally with these neurologic symptoms make a diagnosis of tuberculous meningitis. It is perfectly consistent for the symptoms to drag for three months or even more.

The neurologic examination showed mask-like facies, a wide based gait, absent abdominal and light cremasteric reflexes, and a deviation to the right when the patient walked with eyes closed. In the "Romberg position" the patient is said to have fallen to the right and backward. I cannot on the basis of this neurologic examination localize a central nervous system lesion. It does not seem to me like a cerebellar tumor, and, as you will see later, the service was looking for tumor in the region of the ventricles.

Lumbar puncture showed at first a low pressure of 40 and later a high initial pressure of 207. Examination of the spinal fluid showed the protein and sugar to be slightly elevated. I am sorry that there is no report of the sugar found in the fluid taken at the second examination. A determination of the amount of sugar is helpful in the diagnosis of tuberculous meningitis since there is usually a progressive fall in sugar though it may have been high at the onset. The protein was unchanged in the second examination. There is no mention of a fibrin clot or a search for tubercle bacilli in the spinal fluid.

The ventriculogram, as I understand it, is normal. I do not know how much stress to put on the fact that at the time of puncture the right ventricle could not be entered since later examination showed that this ventricle did

fill with air. We will have to ask the neurologists about this point.

On the neurologic side then it seems to me that the evidence is against tuberculous meningitis because the apical fluid examination showed a normal cell count and a normal sugar so far as these examinations were made. There is no definite evidence of a tumor involving the walls of the ventricle. There are no characteristic cerebellar symptoms. If then, one is trying to make a single diagnosis with an etiological factor that would explain both the respiratory and central nervous symptoms and had already made up his mind that there was miliary tuberculosis in the lungs, the natural conclusion would have to be that the cerebral symptoms were due to a tuberculoma rather than meningitis. Just where the tuberculoma is located, I will not attempt to say. There is no proof that it is near the ventricle or in the cerebellum. I should guess that it was a cerebral tuberculoma.

I do not believe that we are dealing with other disease conditions which might give the two sets of symptoms in the lung and brain these possibilities being bronchiogenic carcinoma, pulmonary abscess, or hypernephroma with metastases to both lungs and brain.

My final diagnosis would then be (1) old tuberculous pleurisy, (2) acute pulmonary tuberculosis of the miliary type, (3) cerebral tuberculoma, (4) generalized miliary tuberculosis with only slight if any involvement of the meninges.

DR. GERALD BLAKE. At entrance this man did not look very ill. He looked sleepy, was well nourished and not complaining of anything except his three months of weakness, ten days headache and more recent hiccup. His subjective symptoms were slowness of speech which he said he had always had but which the family said had increased within the last three months. He also had blurring of the right disc, nystagmus and noticeable lassitude. The signs were, as described of a healed process at the right base and the early process by x-ray at the apex. It was impossible to say whether that was active or not. We did not get much help from the first lumbar puncture and his course was gradually downhill with rather few changes in the neurologic signs. Following the second lumbar puncture within fifteen minutes he stopped breathing and then for about half an hour he breathed three or four times normally and then would stop for fifteen or twenty seconds, not the Cheyne Stokes type but an abrupt stopping and abrupt beginning without much change in color. He was stimulated and continued to breathe in this way. The neurologic service saw him again and took him over for further investigation.

CLINICAL DIAGNOSES

Pulmonary tuberculosis
Coma, undetermined origin

DR. DONALD S. KING'S DIAGNOSES

Old tuberculous pleurisy
Acute pulmonary tuberculosis of the miliary type
Cerebral tuberculoma.
Generalized miliary tuberculosis with only slight if any involvement of the meninges

ANATOMICAL DIAGNOSES

Miliary tuberculosis of the lungs
Pleuritis, chronic, fibrous, right
Solitary tubercle of the medulla
Tuberculosis of the adrenals, bilateral
Atherosclerosis, slight, aortic and coronary
Operative wound. Ventriculography

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY. Members of the neurological service were evidently not very anxious to commit themselves on this patient. Various possibilities were suggested such as a lesion in one of the cerebral hemispheres, possibly a tuberculoma, possibly abscess or tumor. Later another note in the record says that the symptoms appear to be due to medullary compression.

The autopsy showed the old fibrous pleurisy and the widespread miliary tuberculosis which were predicted. The tuberculoma was also found though no one had succeeded in localizing it. It was not quite a centimeter in diameter and lay in the right side of the medulla just in the region of the olive. There was no meningitis. The surprise of the autopsy was the finding that both adrenals were almost completely replaced by large tuberculous masses. Only a small fragment of the cortex about half a centimeter in diameter was left undestroyed. That alone stood between this patient and Addison's disease.

CASE 22242

PRESENTATION OF CASE

A fourteen year old white native schoolgirl was admitted complaining of pain in the left knee.

About one month before entry the patient began having pain in the left knee which was followed in a few days by slight swelling and limitation of motion. The pain occurred first in the popliteal region but after one week appeared anteriorly as well. Walking caused no increase in discomfort but standing for a short period produced aching pain along the lateral aspect of the thigh and calf. Tenderness gradually ensued and the pain became constant both night and day. It was worse between 5:00 and 7:00 A.M., when it became rather throbbing in character. As limitation of motion progressed the patient became unable to walk up or down stairs. No history of contributory trauma was obtainable.

Physical examination showed a slender slightly undernourished girl in no acute discomfort. Except for the left lower extremity the examination was essentially negative. The affected knee was held by preference in approximately 150° extension, it could not be further extended but could be flexed to 80°. The leg was normal but the knee showed a visible fullness extending up and about the thigh for a distance of three inches above the joint. At the upper margin of the patella the circumference was fourteen and a half inches compared with twelve and a half inches on the right. Some evidence of fluid in the joint was elicited. The external femoral condyle was enlarged, bony in consistency, and exquisitely tender. There was tenderness to a lesser degree about the remainder of the knee. On a later examination tenderness and bone-like overgrowth could be indistinctly made out on the interosseous margin of the upper end of the tibia just lateral to the patellar tuberosity. The inguinal lymph nodes were not remarkable.

The temperature, pulse, and respirations were normal.

Examination of the urine showed a specific gravity of 1.020 with a faint trace of albumin and a positive reaction to the Benedict's test. The degree of this reaction was not noted. Tests for diacetic acid were positive. Examination for Bence-Jones bodies was negative. The blood showed a red cell count of 4,400,000, with a hemoglobin of 100 per cent. The white cell count was 8,600, 60 per cent polymorphonuclears. Tuberculin and Hinton tests were negative. The serum calcium was 10.8 milligrams and the phosphorus 5.00. The phosphatase was 8.6 units, Bodansky method.

X-ray examination showed a fusiform soft tissue thickening surrounding the lower end of the femur. The cortex in the involved area was eroded and at the margins of the lesion on the shaft the periosteum was separated and exhibited typical lipping. There was ray spicule formation but no bone atrophy and the joint was not involved. A similar lesion was present at the upper end of the tibia, posteriorly and laterally. This also showed spicule formation and elevation of the periosteum. No definite soft tissue tumor was identified. Films of the bones, skull, and the chest showed no significant abnormality. Later films showed, in addition, bone destruction in both tumors.

On the ninth hospital day, operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. JOSEPH S. BARR: This is the case history of a fourteen year old white schoolgirl who began to have pain in the left knee four weeks before entry. The onset was insidious without history of trauma. At first localized to the popliteal space, the pain gradually spread until the whole knee was involved. There was

no particular change in the amount of discomfort caused by change in position or by weight bearing. The pain was throbbing in character, present night and day, and seemed to be worse early in the morning. The knee began to flex, motion was limited, and finally the patient was unable to walk.

This history is suggestive of a malignant process or of a subacute infectious process such as tuberculosis or Brodie's abscess. The history of disability in children is notoriously unreliable, and the diagnosis hinges much more on the physical findings and laboratory tests than on the history. On physical examination nothing remarkable was noted except for the left lower extremity. The knee showed definite limitation of both flexion and extension. There was apparently a slight excess of fluid in the joint. The lower end of the femur was enlarged, the swelling being bony in consistency, and exquisitely tender. There was less definite tenderness about the remainder of the knee. The vague findings in the tibia will become significant when interpreted in the light of the x-ray examination. The temperature, pulse, and respirations were normal. Examination of the urine showed a faint trace of albumin, and the Bence-Jones reaction, as one would expect, was negative. The positive reaction to Benedict's test and the presence of diacetic acid can have no significant relationship to her bone lesions. Blood examination was essentially negative except for slight anemia. We note the white cell count of 8,600, with only 60 per cent polymorphonuclears. The tuberculin and Hinton tests were negative. The serum calcium was 10.8 milligrams, phosphorus 5 milligrams per 100 cubic centimeters, and phosphatase 8.6 units.

These data yield us definite information and serve to rule out some of the diagnostic possibilities. Tuberculosis will practically always give a positive tuberculin test unless there is an overwhelming infection present, which would not seem to be so in this case. A single negative Hinton test does not eliminate the possibility of lues, but makes it unlikely. The normal temperature and pulse with a normal white cell count and differential would seem to rule out pyogenic infection. On the other hand, the physical examination and laboratory studies are entirely compatible with the diagnosis of primary malignancy, presumably of the lower end of the femur. Osteogenic sarcoma is most common in this age group, and this is a perfectly typical history and physical examination of such a case. The phosphatase is moderately elevated in this case, and I believe that is true of malignancy involving epiphyses.

The extraordinary interest in this case centers around the x-ray examination. The appearance of the lower end of the femur is quite characteristic of primary osteogenic sarcoma. The cortex is eroded. The periosteum is sep-

arated and there is typical ray spiculae formation without involvement of the joint, but a similar lesion is also present in the upper end of the tibia, particularly evident on its posterior and lateral aspects. X-rays taken eight days after the original films showed increased bone destruction in both the tibia and the femur. If either the lesion in the femur or the tibia were there alone, this only reasonable diagnosis would be osteogenic sarcoma. To have two primary bone tumors developing simultaneously must be extraordinarily rare. I know of no such case reported in the literature. Simultaneous development of tumors in brothers and sisters has been reported. I can think however of no alternative diagnosis which would give this characteristic picture. Metastatic bone lesions in this age group are rare and no primary focus was found on physical examination. I presume that one of these two lesions might be primary with secondary involvement of the other bone by direct extension through the soft tissues around the joint. This occurs rarely if ever as the mechanism of dissemination through the blood stream or lymphatics does not permit of direct extension past a joint line into the adjacent bony structure. I am therefore forced to make a diagnosis of a double primary bone malignancy, in spite of the fact that I have never heard of such a case occurring.

If this diagnosis is correct the prognosis is practically hopeless, for in this age group the primary osteogenic sarcomas are uniformly rapidly fatal.

DR. CHANNING C. SIMMONS: I should agree with the foregoing remarks of Dr. Barr with one exception, that is as to the prognosis. It is admittedly bad but there are on record in this hospital several cases of proved osteogenic sarcoma living without disease five or more years after operation.

As a matter of record it is interesting to note that twelve days after amputation the blood phosphatase fell to 2.68 units, Bodansky method.

PREOPERATIVE DIAGNOSIS

Osteogenic sarcoma of the left leg

DR. JOSEPH S. BARR'S DIAGNOSIS

Primary malignant bone tumor lower end of the left femur and the upper end of the left tibia probably osteogenic sarcoma of the osteoblastic, osteolytic type

PATHOLOGIC DIAGNOSIS

Osteogenic sarcomas of the femur and tibia

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY: The unusual clinical picture which the patient presented natur-

ally aroused a great deal of interest and Dr. Codman was appealed to for an opinion about it. He wrote the following note:

"The films seem typical of osteogenic sarcoma in both the femur and tibia. I have never seen juxta-epiphyseal syphilis have this appearance although it occurs above and below the knee as this does it is usually chiefly osteolytic. If the Wassermann is negative amputation is indicated. Within a year I saw an article in the *Journal of the American Medical Association* reporting a number of instances of osteogenic sarcoma in the same family of children. In one case I think, two tumors occurred in the same patient. I know of no other case of the kind."

Other opinions which were suggested naturally included metastatic involvement of the bones and also Ewing's tumor. The x-ray pictures however, were much more typical of osteogenic sarcoma than of Ewing's tumor and the patient did not show the febrile reaction which is so common with this tumor.

After a week of study she was operated upon by Dr. Simmons. A biopsy of the femoral tumor was done and following a frozen section diagnosis he did an amputation just below the lesser trochanter of the femur. When the two bones were dissected out in the laboratory we found osteogenic sarcomas of both the femur and the tibia. The tumor of the femur encircled the shaft for a distance of 10 centimeters, beginning at a point 15 cm. above the lateral condyle. The tumor of the tibia was on the lateral surface of the upper third of the bone and projected chiefly into the interosseous space so that it was naturally difficult to make out on physical examination. No evidence of any connection between the two masses could be found and the knee joint was not invaded by either tumor.

On microscopic examination there was a considerable difference in the histologic character of the two tumors. The one from the femur would do well for a textbook illustration of a typical osteogenic sarcoma. In various areas it showed pure fibroblastic zones, islands of relatively well-differentiated cartilage isomellae of osteoid material, and trabeculae of well formed bone. The tumor from the tibia in contrast showed no trace of cartilage or bone formation and appeared to be entirely fibroblastic in its differentiation. It contained a very high number of multinucleated tumor giant cells. That it too, however, should be classed in the general group of osteogenic sarcomas admits of little doubt in view of its location and gross character. This is the first case that any of us have seen of multiple osteogenic sarcomas in a single patient and, as Dr. Codman has pointed out, cases are extremely rare in the literature and in the material of the registry of bone sarcomas.

CONTRARY OPINIONS RESPECTING THE USE OF ANALGESIC DRUGS IN CHILD- BIRTH

At the annual meeting of the American Medical Association in the section on obstetrics and gynecology three papers were read this year on methods for the amelioration of labor pains. These contributions were made by physicians of ability and judgment, working in well-organized clinics and all included a sufficiently large number of cases to be of value. A discussion arose which, if reports in the lay press are true, was characterized by considerable vigor, and appeared at times to have been slightly tinged with acrimony. Those who dissented did not hold that the methods described were inefficient, then contention was that it was wrong to relieve the pains of childbirth. Such a mental attitude recalls the protest by the established Church of England which greeted Sir James Young Simpson's use of chloroform for that purpose in 1847. The objection raised eighty-nine years ago was that of impiety and

the aid was invoked of the third chapter of Genesis where it is written that women should bring forth children in sorrow. Continuing this same unworthy spirit of revenge upon Eve for her misdemeanors in the Garden of Eden it was decreed that all of her daughters should endure the same unpleasant experience. Today, possibly because not so many people are familiar with the Bible, the attack has shifted from the soul to the psyche. We are told that if a woman is prevented from enjoying the pains of childbirth it may cause great damage to her personality, and the development of nervous disorders will be the price for an escape from reality. Although the pains of labor are apparently beneficial to the woman who is so fortunate as to enjoy them, we are also told that they may be made to vanish if the fear of childbirth is eliminated by suggestion both in the prenatal period and during labor by careful explanation of their physiology. An individual who has sufficient powers of persuasion to convince a parturient woman in full cry that she is mistaken, that she is not suffering at all, or who can induce a light anesthesia by a bedside description of the autonomic nervous system has gifts that are wasted in the practice of medicine.

It was further stated that the use of analgesic drugs produced high maternal and fetal mortalities, although no statistics were given to substantiate these contentions, nor are any such figures available in the literature. Since no proof of these serious charges were given we must accept them solely as the personal opinions of those who advanced them and assign to them as much or as little value as we please. If the experience of one Boston hospital is of any importance it may be of interest to note that during the years that analgesic drugs have been largely used the neonatal death rate from intracranial hemorrhage has fallen to less than one third of its former figure while the death rate from atelectasis and asphyxia has remained unchanged. Such results do not indicate that the use of these drugs has led to violent operative deliveries, nor do they show that more babies have died because they were employed. On the other hand, it is the opinion of many that analgesics, properly used, protect the interests of both mother and infant since the knowledge that the patient is not suffering enables the obstetrician to await the normal conclusion of labor and removes any temptation, because of her agony and importunities, to operate too soon.

One needs but to question a few women who have had babies without any anesthetic and have had a subsequent delivery under analgesic drugs to be convinced that such methods are in the nature of a great blessing. It would require much argument to convince these women that

they did not suffer at their prior deliveries, or that it was good for their nervous systems, or that they should have their next child with out anesthesia.

While the benefits derived from analgesic drugs are great, they should be used by the proper persons in the proper patients and in the proper places. Physicians who employ these drugs should be trained in their use and should be thoroughly familiar with their pharmacological action. Once medication has been given, the physician must be with the patient on ready call. From the time the drugs are first given until the patient is fully awake she must never be left unattended by a nurse who must be thoroughly familiar with the use of these agents. These drugs are never to be used in the patient's home; they belong essentially to hospitals with good maternity departments. These methods are not recommended for practitioners who do obstetrics as part of a general practice and who lack the time and experience to carry them out nor are they advocated for the small hospital with an occasional obstetrical case. These methods, moreover, are not suitable for abnormal cases and they may prove dangerous when employed in the presence of respiratory infections or when the patient has recently eaten.

THE CYTODIAGNOSIS OF MALIGNANCY

It has long been claimed by McCarty of the Mayo Clinic that the malignant cell has one pathognomonic characteristic—a very large nucleolus, far larger than occurs in most normal cells. Several of his students have confirmed this diagnostic point. However remembering the large nucleoli of the liver parenchymal cell and the nerve cell, most pathologists have been reluctant to regard nucleolar size as specifically diagnostic of malignancy. In fact, most of them are unwilling to make any differentiation between malignant and benign cells on cytologic characteristics alone.

Research for specific stains for malignant cells has met with the same degree of success as would be expected from any other rainbow-end quest. Lewis¹ in summing up the characteristics of the malignant cell in contrast with the benign was forced to depend on the time-honored criteria of anaplasia of abnormal mitotic forms, and of altered function. However, any or all of these can be duplicated in repair. Thus in simple epithelial repair of the skin we see loss of differentiation, rapid growth, mitotic activity very occasionally even with abnormal mitoses occurring.

An interesting report in this regard is made by Foote who found that the degree of aciculation in distinguishing malignant from benign ascitic fluid was only 70 per cent, using all

available criteria for differentiating malignant and nonmalignant cells. His conclusion was that in the absence of clear-cut histologic organization, that is, the formation of glandules or cell clusters, the differentiation of malignant and nonmalignant cells was uncertain.

This difficulty of distinguishing cells has considerable bearing on the practical value of the so-called punch biopsy advocated by a few pathologists and some surgeons. The punch biopsy if it obtains only isolated cells, rather than a definite plug of tissue, is of low reliability. Its chief value lies in instances where the diagnosis of malignancy hinges not on the recognition of the detail of cells involved but the finding of cells of specific character in a given site. Thus if the patient has had cancer of the lip and keratinized epithelial cells are obtained from a punch biopsy of a neck node, it is a reasonable assumption that metastasis of cancer of the lip has occurred to the node. On the other hand if one obtains poorly differentiated lymphocytes from the node the diagnosis of lymphoma certainly would not be justified, even though mitotic figures may be present. All in all the assumption seems justified both on theoretical grounds and from practical experience that the diagnosis of malignancy from a single cell is highly inaccurate and may react unfavorably on the welfare of the patient.

AN ANTHROPOLOGIST SPEAKS HIS MIND

Dr. E. A. Hooton, professor of anthropology at Harvard University speaking before the American Association of Physical Anthropologists in New Haven last month demonstrated that no justification exists for the preferment of Nordic and Aryan stocks among the recognized racial types. A study carried on at Harvard among three social groups—the cream of the population, the middle class and the criminal class according to a dispatch to *The Boston Herald*, showed that the racial types were represented in the same proportion in all three groups.

Maintaining that every racial strain should be purified by sterilization of its criminal insane and diseased, Dr. Hooton denounced as 'ridiculous and pernicious' the 'doctrines of racial inequality which have become a menace to the peace of the world and have brought tragedy upon millions.' Every one of our so-called racial types in the series studied according to Dr. Hooton is represented by a substantial body of convicted felons at one end and a group of eminently respectable and intelligent citizens at the other.

In the words of the speaker, "one does not need to be an anthropologist to recognize that there is rampant, not only in this country but elsewhere in the world, a selfish stupidity, which reeks of human decay and degeneration. It manifests itself in some quarters by brutal oppression of minorities selected for ill treatment on account of religious, linguistic or fancied racial differences.

"Elsewhere it is expressed in shameless aggression against defenseless primitive peoples. Here in the United States it is horribly evident in maudlin sympathy for criminals and in the toleration of crime that seems to characterize the mass of our population, in the looting of our national treasury in the name of patriotism, the wasting of our resources for political patronage, and even perhaps in muddle-headed efforts at national planning and regimentation, which bid fair to reduce us to the unfortunate economic status of those fabled inhabitants of the Scilly islands, who were 'forced to eke out a precarious livelihood by taking in each other's washing'."

MASSACHUSETTS TUBERCULOSIS LEAGUE

GREETINGS BY DR. HENRY D. CHADWICK,
STATE COMMISSIONER OF PUBLIC HEALTH

After reviewing the progress of tuberculosis work in Massachusetts, Dr. Henry D. Chadwick, State Commissioner of Public Health, spoke of the 200 new beds at Westfield State Sanatorium of which one fourth are for cancer and three fourths for tuberculosis. He also mentioned the 150 new beds in the Middlesex County Sanatorium, as well as the new nursing home in Norfolk County Hospital which will release some ten beds for patients in that institution. In each project 45 per cent of the cost is paid from the Public Works Administration.

Dr. Chadwick pointed out that Massachusetts has 24 beds per annual death prior to use of this new construction, so this state will be well equipped to hospitalize its tuberculous. It will greatly reduce the centers of tuberculosis infection in the communities. In this connection may be mentioned that few states have yet passed the national goal of tuberculosis workers for two hospital beds per annual tuberculosis death.

THE PREVENTION AND CONTROL OF TUBERCULOSIS IN THE COMMONWEALTH OF MASSACHUSETTS WITH SPECIAL REFERENCE TO THE ACTIVITIES OF THE MASSACHUSETTS TUBERCULOSIS LEAGUE*

BY FREDERICK T. LORD, M.D.

We meet to celebrate the twenty third anniversary of the establishment of the League.

During the past year Mr. Frank Kiernan resigned after ten years as Executive Secretary of the League.

*President's Address presented at the Annual Meeting at Springfield April 8, 1936.

to accept the position of Executive Secretary of the New York Tuberculosis and Health Association. During his term of service the machinery of the League and its affiliated organizations operated efficiently and smoothly and we owe much to his leadership organizing ability energy and enthusiasm. His place has been taken by Mr. Arthur J. Strawson, who acted as Field Secretary for the National Tuberculosis Association for a number of years and who resigned his position as Executive Secretary for Southern Worcester County to come to us.

During the past year Miss Jean V. Latimer, Educational Secretary for seven years, resigned to take a position in another field. Through her efforts valuable progress was made in increasing the interest of school authorities and the public in child health education. Her Teaching Unit on Tuberculosis for Secondary Schools is now used in many large cities of the country. Miss Elma I. Perkins succeeds Miss Latimer as Educational Secretary.

THE MASSACHUSETTS STATE HEALTH COMMISSION

In 1935 in accordance with an act of the Legislature of May 10 His Excellency Governor Curley appointed a commission to collect data and make recommendations concerning a revision of the Public Health Laws of the Commonwealth. The Commonwealth Fund of New York generously contributed \$10,000 to defray expenses. Various aspects of matters pertaining to Public Health have been assigned by the commission to subcommittees. Among these a subcommittee on Tuberculosis Control was appointed. This subcommittee has under consideration and will make a report to the Commission on the incidence of tuberculosis, case-finding, facilities for and adequacy of sanatorium treatment, rehabilitation services, health education, voluntary agencies, summer health camps and prevention, open air schools and medical education as it relates to tuberculosis.

An extended discussion of these matters is therefore unnecessary and I confine my remarks to a brief statement of the present situation with respect to the declining mortality, institutional care, tuberculosis dispensaries and case-finding.

DECLINING DEATH RATE

The rates of mortality and morbidity from tuberculosis continue to fall in spite of the severe industrial depression and there is the prospect of the practical elimination of the disease as a serious public health problem. The favorable showing is to be ascribed to environmental rather than natural factors. Improved standards of living and a diminishing amount of community infection through education and hospitalization are largely responsible.

In Massachusetts the case-fatality ratio for pulmonary tuberculosis has fallen from 395 per 100,000 living in 1887 to 43.8 in 1934 and 41.6 in 1935. Considering actual figures there were 1814 deaths from the disease in 1935 and estimating nine cases per

death there are about 16,000 patients to be cared for and prevented from infecting others.

In spite of the encouraging decline tuberculosis is still a major public health problem and the chief cause of death from disease in early adult life. New methods of attack maintain an unabated demand on our resources.

INSTITUTIONAL CARE

Adequate facilities for hospitalization are essential and accomplish the double purpose of the elimination of spread of the disease by contact and the promotion of recovery through the application of modern therapeutic measures. There are in Massachusetts 4500 beds in federal state county municipal and private institutions or 248 beds per death. Enlargement of the Middlesex County Sanatorium and the Westfield State Sanatorium by 150 beds each may be expected to provide a sufficient total provision to meet the needs of the state.

The state and county sanatoria have on the whole furnished adequate and easily available service. Some of the tuberculosis hospitals in cities or towns have on the other hand been handicapped by small size and inability adequately to apply collapse therapy. Two of these institutions have been deprived of the subsidy of five dollars per week for indigent patients because of failure to comply with standards imposed by the State Department of Health. It would seem best eventually in the interest of economy and of quality of service with few exceptions for cities and towns to transfer the responsibility for the care of tuberculous patients to the state or county sanatoria in their respective districts.

TUBERCULOSIS DISPENSARIES

It is now no longer necessary for towns of 50,000 population and over to maintain tuberculosis dispensaries and it would seem desirable in the interest of economy and of efficiency of service for cities and towns with few exceptions to shift the responsibility for diagnostic service to the state or county sanatoria.

CASE FINDING

Early diagnosis of extreme importance to the patient and the community is in large measure a failure when dependence is placed on the patient to present himself for investigation and without the routine use of the x-ray. Significant symptoms and physical signs are frequently lacking in the early stages of the disease and it seems desirable to select easily available groups and those with more than the usual chance of the disease for investigation.

In the continuing project following the termination of the Ten Year Program in June 1934 facilities are available for the routine examination annually of children in the seventh, ninth and eleventh grades. In a few of the larger cities the examination of school children is carried out under the direction of local boards of health. The state and county sanatoria furnish neighborhood service on request from the local board of health and the school committee.

Where towns are near enough, the work is done at the sanatorium. For the more remote towns in the district a traveling clinic from the sanatorium is available. For isolated communities where the sanatoria are unable to furnish such service, the State Department of Public Health provides portable x-ray units and a clinic unit until the entire responsibility can be taken over by the local community.

The family contacts of tuberculous children and of tuberculous patients in sanatoria and in the practice of physicians should be investigated, including an x-ray examination.

As a matter of protection for children, all school teachers should have an x-ray examination or be tested with tuberculin and the reactors x-rayed. School teachers with active tuberculosis should not be permitted to teach. All diabetics should have an x-ray examination when the diagnosis is made.

MEDICAL EDUCATION

The success of measures for the prevention and control of tuberculosis in the community depends in large measure on the participation in the program of adequately trained physicians in general practice. The standards of medical education and licensure in Massachusetts are too low. In consequence, physicians may still enter practice inadequately equipped. At least two years of premedical college training are desirable. Of six medical schools in the country incapable of the proper education of medical students, two are in Massachusetts.*

LICENSURE FOR PRACTICE

Graduation from medical schools of approved standing is the most important qualification for practice but Massachusetts is one of sixteen states in the Union in which graduates of unapproved medical schools are licensed to practice.

Massachusetts is among the worst offenders with respect to qualifications for practice as no attention is paid under the present law to the scope or quality of instruction in the medical school in the acceptance of the candidate for examination. Authority (as in House Bill 34) should be given the licensing board to accept for examination only those candidates who are graduates of approved medical schools.

PUBLIC HEALTH

Extension of public health service through increased financial support and the establishment of more full-time health officers is desirable. Organization should be on the basis of the unit of local government and is often best on a county basis to spread the cost over a larger population.

A difficulty in the carrying out of an adequate community health program is the lack of appreciation on the part of the public of its importance. Education by unofficial health agencies will improve the situation and lead to the wider acceptance of

well established measures for the control of communicable disease. As an indication of shortcomings in this direction, in the investigation of school children for tuberculosis in the Ten Year Program paid for by taxes, lack of parental consent deprived about one out of three children in the grade schools and one out of two in the high schools of the advantage of the investigation.

Of the two demonstration centers in Massachusetts, it is encouraging that one of them, that in the Nashoba district, embracing ten towns, will itself carry on the improved service with assistance from the State and without further reliance on the Commonwealth Fund of New York.

ANNUAL REPORT OF THE EXECUTIVE SECRETARY*

YEAR ENDING APRIL 8, 1936

BY ARTHUR J. STRAWSON

In coming before you for the first time I wish to extend to you my sympathy in the loss of your tried and true executive, Mr. Frank Kiernan. Your loss is a gain for the New York City Tuberculosis and Health Association.

In reviewing the past twelve months' work at this 23rd Annual Meeting your executive secretary who came only in January, 1936, will include a report on nine months of program prior to his coming to the Massachusetts Tuberculosis League. His work has begun pleasantly. He asks your indulgence while he becomes familiar with the programs and problems of all the affiliated associations.

REHABILITATION OF TUBERCULOSIS PATIENTS

In 1935 was completed at Middlesex County Sanatorium in cooperation with Dr. Sumner H. Remick, Medical Director, a study of what may be done to aid recovering tuberculosis patients in selecting an occupation and in preparing to earn a better living despite their changed physical condition.

This study was financed by the League with the National Tuberculosis Association supplying at first Mrs. B. W. Burhoe, Rehabilitation Secretary. Dr. John C. Flanagan of Harvard University was found to have the qualifications required and, on part time, did much of the work.

It is now recommended that such a course might better be given by a full-time sanatorium employee who selects from time to time, lecturers or teachers in specialized lines. Such a person would be a Director of Social Adjustment or Rehabilitation. Under this person would be a social worker, occupational therapist and librarian. He would know enough of psychiatry to diagnose mental cases and to assist them. His work would be with physicians and nurses whose programs he should understand. Finally, he must have a deep social interest. With out such a worker the more important parts of the rehabilitation program may better be omitted.

*EDITORIAL NOTE: An amended bill raising the standards of medical education under the title of House 17-0 was enacted and signed by the Governor April 30, 1936.

*Presented at the Annual Meeting of the Massachusetts Tuberculosis League at Springfield April 8, 1936.

MASSACHUSETTS UNDER THE MICROSCOPE

A report was made last year on the formation and financing of the Massachusetts State Health Commission. Under the direction of Dr Carl E. Buck, of the American Public Health Association and fourteen Massachusetts committees the health work of the Commonwealth is now being intensively studied. Our President Executive Secretary and Health Education Secretary are adding on various committees. The League Office did much of the Commission's clerical work in the organization period. In 1937 will arise the task of putting to work the Commission's recommendations. Obviously it will call for many changes of procedure in the conduct of public and voluntary health work. Into this project it is hoped that all tuberculosis and other health related agencies of the Commonwealth will, in 1937 enter with enthusiasm. The final report of the Commission is due by the end of this year.

GRANITE DUST CONTROL

Through its Committee on Granite Dust Control a study is now in progress on control methods in smaller granite cutting industries. The League has joined other New England state tuberculosis associations as well as various national health and insurance agencies in helping Mr Manfred Bowditch of the Division of Occupational Hygiene in the State Department of Labor and Industries to conduct this study.

Delay in completing the study was due to difficulty in getting a suitable group of stone workers paid for by the Public Works Administration to follow up those paid for by the terminated Federal Emergency Relief Administration. Happily this problem was well solved the work progresses and a report should be completed within the coming summer. The report to be published will give cost estimates and efficiencies of the several installations within the cost range of the smaller granite cutting companies. Thereafter some local associations may be able to aid in securing use of newer dust stopping devices.

DIABETES STUDY

With the aid of a financial contribution for the purpose a study was made of the final illness of the 301 diabetics who died in Boston in 1935. For this work the Diabetes Committee of the League found the services of Dr George W. Lynch eminently satisfactory.

The study may result in securing a more adequate and correct use of Insulin. Diabetic persons seem to be more subject to tuberculosis than most others while diabetic children as recent studies show are ten times more likely to develop tuberculosis than are nondiabetic children.

LOWELL STUDY

In the spring of 1935 a study of the mortality and morbidity statistics for tuberculosis was completed. Tabulations were made by age sex ward distribution, form of the disease, number of contacts in families, case-reporting etc. The report was submitted

to the Lowell Tuberculosis Association which in turn passed it on to the co-operative City Director of Health for his active consideration. Through the study a more or less complete picture of the tuberculosis problem in Lowell was secured according to areas of concentration. Such a picture is always helpful to a health agency public or private in shaping its program to concentrate its efforts where ever they are most needed. This branch of service by the League staff is practically available to any Massachusetts association interested in making a similar study of its tuberculosis problem.

HEALTH EDUCATION INSTITUTE

At Fitchburg State Normal College led by the Northern Worcester County Public Health Association the Southern Worcester County Health Association, Franklin County Health Association the State League and other agencies united to provide a health education institute for one day. Dr Fredrick W. Maroney of Teachers College Columbia University New York City was the principal speaker and a jury on health education was conducted. The many superintendents principals and teachers in attendance seemed well pleased and well repaid.

ASSOCIATION PROGRAM DEVELOPMENT

The affiliated associations and League early in 1935 were fortunate to have a study made of their programs by Dr Philip P. Jacobs the vigorous long time worker of the National Tuberculosis Association. Since the study and report on programs of the associations many of the recommendations have been adopted. Others merely await revision of conditions. While use of still other recommendations seems impractical the effort leads us all to try out our established methods to make sure which ones need replacement or revision.

After the association program study a very well attended State Tuberculosis Institute was conducted in Boston by Dr Philip P. Jacobs for all tuberculosis workers of Massachusetts.

EARLY DIAGNOSIS CAMPAIGN

The spring health education campaign of local state and national tuberculosis voluntary agencies maintains a vigorous program. Not all associations use it but some derive large benefits. Not least is the public appearance of the local associations in a health campaign wherein no funds are sought or mentioned. Besides advancing popular education against tuberculosis the Early Diagnosis Campaign thus improves the community status of our local associations. The National Association prints material for the campaign on a national scale with resultant cost savings to all concerned.

In time for the 1936 Campaign the League procured Eastman Classroom Films for the use of local associations. The following new films are available: Bacteria Breathing Homo Nursing (Routine Procedure) Posture and Care of the Teeth.

In the older films now largely rehabilitated are Story of My Life by Tee Bee Dolay is Dangerous,

Consequences, Tuberculosis—How it May be Avoided and The Kid Comes Through.

All of these films, both old and new, except Consequences, are available in 16 mm size. While there is no charge for their use the local associations pay the return transportation.

SUMMER HEALTH CAMPS

At Worcester all summer health camp workers were invited by the League to discuss among themselves and with Dr. Henry D. Chadwick, State Commissioner of Public Health, the selection of camp children so as best to advance tuberculosis prevention. Such meetings have much to do with the improvement in various lines of summer health camp standards. Without such efforts camps tend to remain or to become recreational camps rather than camps for tuberculosis prevention. At present several of the Associations have extended the camp period to eight weeks, while others are struggling to do so.

MASSACHUSETTS HEALTH JOURNAL

The Massachusetts Health Journal was continued as a plan for aiding and encouraging the many workers in tuberculosis throughout the Commonwealth. Besides the *Journal*, twenty-six special mimeographed bulletins were sent to local workers on routine or special matters.

ORGANIZATION

After much loss of population from Haverhill and considerable financial difficulty the Haverhill Tuberculosis Association rather wisely voted on March 1, 1936, to consolidate with the Essex County Health Association. This Association with its capable executive secretary and health education worker can give Haverhill good service. Miss Christine B. Higgins, R.N., the former Haverhill executive, has fortunately secured a position with the State Department of Public Health in its work of social security.

In Southern Worcester County, Mr. Doyle E. Hinton, formerly executive of the Delaware Tuberculosis Society, has been appointed as executive secretary.

In the Malden Tuberculosis and Health Association, Mrs. Frederick R. Makepeace, R.N., was appointed secretary in place of Mrs. F. Anna Green, resigned. Mrs. Green had been secretary of that Association since its formation in 1911.

SEAL SALE

Preparatory to the opening of the 1935 Seal Sale the League secured the expert Seal Sale organization services of Miss Frances E. Brophy from the National Tuberculosis Association to conduct intensive courses with workers in all sections of the State.

As in most other states, we are rising from the depths reached in 1932 and 1933. In 1933 the Christmas Seal Sale amounted to \$185,913, in 1934, \$189,259. As a few associations have not settled up their Seal Sale account with the League, we can

not today tell the 1935 total. We expect that the total sale for the state will pass the \$195,000 mark.

Of county associations reporting to date Southern Worcester has the highest gain over 1934. It rivals its 1934 sale by \$1,515.49. Of city associations reporting to date Lawrence has the largest gain over 1934. Its gain is \$265. If the history of the 1921 depression repeats itself, our Seal Sale may be made to increase for the next few years.

SCHOOL CHEST CLINICS

The opportunity our associations have in the field of the new school chest clinics, Miss Perkins will fully present. In this connection the League is happy to find its tuberculosis teaching unit able to aid the schools and sanatoria by increasing the number of pupils consenting to the tests and x-rays.

LEGISLATION

Considerable has been done, particularly to advance the measure for better education of persons studying for medicine. The local associations also helped to secure the passage of this measure which for twenty-five years, according to Dr. Walter P. Bowers, Editor of *The New England Journal of Medicine*, has been knocking at the doors of our Legislature. Having passed with a good majority, it will soon await the favoring pen of our Governor.*

In 1937 the aid of all associations will be needed to secure passage of the health legislation now being worked out by the Massachusetts State Health Commission. The Commission will have the new legislative proposals drafted in bills ready for your consideration and backing.

Your executive secretary wishes for each worker and association that the coming year may be a happy and successful one.

*This Bill under the title of House 1720 was signed by Governor Curley April 30, 1936.

ANNUAL REPORT OF EDUCATIONAL SECRETARY*

BY ELNA I. PERKINS

In giving an account of the beginning of my work as Educational Secretary of the Massachusetts Tuberculosis League, I wish first to express my appreciation of the work of my predecessor, Miss Jean V. Latimer, who served the League for seven years with excellent leadership and capability in the field of health education. Her accomplishments have shown the way to follow in both direction and method and we are most grateful for her fine example and for the materials which she created that we are now using.

After considering our well established program and the work of the official agencies in Massachusetts, the greatest need of the immediate year appeared to be an extension of educational work on tuberculosis in all the junior and senior high schools.

*Presented at the Annual Meeting of the Massachusetts Tuberculosis League at Springfield April 8, 1936.

in the state with the purposes of establishing the subject more definitely in courses of study and in aiding the new tuberculin testing program inaugurated last year in the seventh ninth and eleventh grades

Dr Frederick T Lord, President of the League in his report made to you last year indicated the need for this work in the schools by saying that the failure to secure as many consents for the tuberculin test from high school pupils as from elementary school pupils in the Chadwick Clinic should be regarded as an indication of our shortcomings in health education. He also said that parental consents should be obtained from more nearly one hundred per cent of parents of children in the grades tested and that the responsibility of the League and the affiliated organizations in this matter is obvious. I wish to give emphasis to Dr Lord's statements and to say that the Educational Secretary has assumed responsibility for the League in developing an educational program on tuberculosis that will directly aid the tuberculin testing work. Our Executive Secretary Mr Strawson gives wholehearted support and assistance in this undertaking with a knowledge of helpful procedures based on his experience as Executive Secretary of the Southern Worcester County Health Association. He and Miss M Eleanor Hanson R.N. Field Secretary of the Southern Worcester County Association accomplished much in promoting the school clinic work last year in cooperation with Dr Edson W Glidden Superintendent of the Worcester County Sanatorium.

May I suggest that every affiliated organization should likewise assume responsibility for very definite co-operation with the sanatoria which do the tuberculin testing the local Boards of Health and the schools in aiding the tuberculin testing work to the end that larger numbers of children may be given the test.

The tuberculosis associations may help the tuberculin testing program by the following definite plans which have proved their value, particularly in Southern Worcester and Essex Counties

Inquire of the sanatoria the time of year when the testing is to be done in each town in the association's territory

Offer to the superintendent of schools in each town at least two months before preparations for the testing are begun the materials which the association can furnish for classroom teaching on tuberculosis

Offer the service of the association or assistance from the League in giving information to principals and teachers at their group meetings

Contact all organizations in the community which could devote a program to the subject of preventing tuberculosis in young people. Have exhibits prepared for libraries or other suitable public meeting places and give pub-

licity to newspapers on the purpose of the tuberculin testing program

After consent blanks have been returned from parents offer the service of a worker from the association to assist the local public health nurses or school nurses in communities having inadequate numbers of nurses to do the necessary home visiting to secure consents from parents

Towns which have not yet had tuberculin testing in their schools under the new arrangement may be helped to see the need for having school clinics by suggestion from the local associations. Since the services of the school clinics are provided by sanatoria on joint request from the local boards of health and school committees, the tuberculosis association may take up the matter with the local boards of health and school committees

Our National Association and the League have printed suitable, helpful materials to offer teachers for classroom use in teaching the subject of tuberculosis. We have the Teaching Unit on Tuberculosis prepared by Miss Latimer which is being used in this state and others increasingly and is much appreciated by teachers who have used it. This year the League reprinted a pamphlet originally published by the National Tuberculosis Association entitled Do Children Have Tuberculosis with a new cover having a picture of the application of the von Pirquet test as used in the school chest clinics in Massachusetts. This pamphlet is intended to serve as a text to be placed in the hands of pupils when the Teaching Unit is used. Many of the publications of the National Association are very helpful to teachers as supplementary material to the Teaching Unit and I recommend wider use of them. The question of who shall pay for this material if used in quantities each year needs to be agreed upon. I believe that Seal Sale funds cannot be used to greater advantage in any community than in the purchase of this material for use in schools. Funds now being spent for milk or other relief purposes might be budgeted for this purpose and have more direct effect in tuberculosis prevention. The policy of spending Seal Sale funds for educational purposes rather than for relief purposes is strongly recommended by our National Tuberculosis Association in the Seal Sale contract. Towns whose Seal Sale Committees have a large percentage of Seal Sale funds to spend locally at their discretion should consider the opportunity they have to furnish literature on tuberculosis to their own local schools. If the county associations are unable to provide literature for all towns from health education budgets

It is fitting to quote Dr Stuart Pritchard former president of the National Tuberculosis Association who referred to the tuberculin test in his address at the National Association meeting in 1934

'Any given child's attitude toward the tuberculin test depends not alone on what he learns from the teacher or the text, but also on the attitude of his mother, his father, other children, the Boy Scout leader, the physician, the dentist the Sunday School teacher, the newspaper and the motion picture—offset against each other with varying weights according to the value the child unconsciously places upon the source"

Dr Pritchard also reminds us in the same address that future health programs will require less crusading and more practical assistance to individuals and communities in the form of organization and education. Let us give practical assistance to the tuberculin testing program in Massachusetts schools in any way that we can.

One other service of the League related to health education I wish to mention as having greater possibilities of usefulness is the free loan library which the League has always maintained. This year the library has been enlarged, and a list of all books printed and distributed. The library is intended to serve the affiliated organizations, and we hope it may be increasingly used by them. One of the chief uses of the library is for exhibits of new and useful books on all phases of health at group meetings of teachers and of nurses. The library is one of the most valuable services in health education offered by the League to all persons interested in public health, and it is hoped that more people may be made acquainted with the opportunity to use it.

During the year, group meetings for public health and school nurses have been held at some sanatoria in co-operation with the local tuberculosis associations, and with assistance from the League on programs. Since these meetings have proved to be very helpful to nurses in instructing them in the newer methods of treatment and prevention of tuberculosis, the League offers assistance to other local associations which may plan similar meetings.

The League has co-operated with several of the state teachers' colleges this year by arranging for Miss Fannie Shaw, School Health Education Secretary, of the National Tuberculosis Association staff, to visit them and talk to classes in health education or special assemblies.

The League has provided in its Health Education budget for institutes for teachers, similar to those successfully conducted in the past two years in co-operation with local associations and school officials. It is hoped that at least three institutes may be arranged for next year.

Our associations have made many fine contributions to health education in schools and communities in past years, and can be expected to continue to apply new knowledge in developing programs that meet the needs of the future. Co-operation with all other agencies is the proved method by which we shall arrive nearer the goal of "equality in health for all men"

REPORT OF TREASURER

Statement of Income and Expense
January 1, 1935 to December 31, 1935

Income

Percentage from Christmas Seal Sale	\$18,925 90
Memberships	346 00
Grant for Study of Diabetes in Boston	500 00
Interest on bank funds	672 27
Salary Refunds from Executive Secretary	250 00
Repayment of Loan by Affiliated Organization	600 00
Total Income	\$21,294 17

Expense

<i>Health Education</i> — Including institutes, books and periodicals, <i>Health Journal</i> , purchase and printing of health pamphlets, travel, salaries	\$7,129 95
<i>Summer Health Camps</i> — Assistance to Affiliated Organizations in securing workers and equipment, visitation and inspection, travel, salaries	723 81
<i>Legislative Work</i> — Including circularization of local associations, conferences, clerical service	390 06
<i>Special Studies</i> — Including Study of Diabetes in Boston in 1935, Study of programs and work of Affiliated Organizations, Social and Vocational Rehabilitation at Middlesex County Sanatorium, and Study of Granite and Dust Control	1,310 87
<i>Administration</i> — Rent, office supplies and equipment, postage and express, telephone, meetings, salaries, printing, etc	3,423 41
<i>Seal Sale</i> — Field service, regional conferences, publicity, newspaper material, telephone, shipping clerk, charges on supplies, salaries, postage	3,651 98
<i>Organization and Field Work</i> — Visitation of local organizations, individual	

and group conferences, public addresses travel salaries reorganization.....	3 536 70
Total Expense.....	\$20 166 78
Excess of Income over Ex pense	1 127.39

HEALTH SECURITY*

BY KENDALL EMERSON M.D.

Managing Director National Tuberculosis
Association

As a result of the years of depression the subject of economic security dominates our social problems. By this we mean that wealth shall be so distributed as to insure to each family such share in national production as may be necessary to provide an income for comfortable living and the avoidance of penury in old age. Among the hindrances to realizing these objectives are improvidence, unemployment and unpredictable disaster. Improvidence is an unfortunate characteristic of many human beings. No social device can wholly ward off its penalties. Unemployment is to an extent an insurance problem. Disaster may come in the form of accident such as fire, flood or cyclone and can be partially offset by insurance also. But the chief unpredictable disaster is that of serious, expensive and prolonged illness with its accompanying loss of earning capacity. No adequate economic security is possible without effective provision for health security as well.

This fact was fully recognized by the planners of the Economic Security Act. That a program for health insurance could not be fabricated for inclusion in this Act is evidence of the prolixity of the problems which such inclusion would involve. An enormous amount of time and effort was expended by wise counsellors in the attempt to solve the puzzle. It is probably greatly to their credit that nothing concrete accrued since a half-digested measure would quite certainly have been worse than none.

I cannot tarry to discuss the polar points of view that have been expressed, my vociferated regard for compulsory health insurance. As in such emotional conflicts personal prejudice has blurred clear thinking and thwarted fair debate. Both sides being human, neither is right. On the whole, coercion at the present moment of heat would invite needless disaster. The reasonable procedure would appear to be to rest on our oars until cooler judgments may prevail. Meanwhile we may profit by the variety of local and more restricted experiments which are in progress. This is consonant with our genius. This clear thinking of the few rarely impresses the herd.

Experience is a costly school but its ripper fruits are more sound and enduring.

Meanwhile it is wholly proper and fitting to examine with interest and some care just where we stand at the moment in this matter of health security. In so doing we are faced with a rather striking paradox. There is general agreement that hard times, the resulting poverty, physical hardship and mental strain wreak havoc with health. Yet in 1933 the year of deepest depression this country struck a new all time low in its mortality rate. Throughout the years of idleness from unemployment and reduced income comes the death rate from tuberculosis supposedly a disease of poverty has continued to decline with its predilection regularly. No grave epidemics have occurred, hospitals have shown no overcrowding. How can such facts be reconciled with the outcry for health security when on the surface at least, we seem to have more of it under conditions of underprivilege than in times of prosperity?

We need invoke no miraculous explanation of this apparent paradox. The bulk of the answer is contained in the two words public health. Consider this matter of health security from the historical angle. What is your health security today as contrasted with that of your grandfather? Seventy-five years ago yellow fever, cholera and plague were still knocking occasionally at our maritime portals. Malaria was rioting unchecked in many parts of our country. Typhoid touched most households in our more crowded centers. Diphtheria put to death thousands of helpless babies annually and tuberculosis was reckoned a fatal disease. Your chance today of surviving the perils and risks of infancy are four times better than your grandfather's. Your life expectancy at birth is twenty years longer than his. You are relatively secure from the hordes of controllable pestilences. For these changes community organization for the administration of preventive medical measures is largely responsible.

Right here I want to pause and stress a most important point in this discussion. Public health is not an abstraction. The public health service does not exist as a disembodied force. Its value hinges exclusively on the personnel engaged in its application. To a major extent the discoveries on which its evolution rests, the methods of practical application of such scientific knowledge have been innovations of that profession which I honor above all others, the profession of medicine. Certain enthusiastic lay partisans there are who fall deliberately or through ignorance to give due weight to these facts. Some even accuse the medical profession as a body of dereliction of its highest duty to maintain the health of the people, forgetting that the successful administration of preventive medicine would be nonexistent were it not for the basic contributions of the medical profession itself. One must not wax oversensitive on this point. Physicians too are human. But to accuse them as a class of lack of sympathy with the progress of every legitimate preventive medical measure is to exhibit a woeful lack of judgment and good sportsmanship.

And so the credit for your health security of today as contrasted with that of your grandfather rests on a foundation well and broadly laid by the profession whose age old duty it has been to prevent as well as to relieve suffering. On this sturdy foundation a splendid corps of workers, some trained as physicians, some as administrators, some as technicians, some as nurses, some as social workers, have been building the structure of modern public health which is bearing fruits at this present time of stress beyond any dream which we could have cherished thirty years ago.

In addition to the medical profession and the public health service another vital fraction, and that a very large one, enters into the equation which has resulted in the degree of improved health security which we enjoy. I refer to the public itself. Without co-operation from this multitude, very scant progress would be possible. A college president once remarked that though you lead a horse to water and can't make him drink, still you may find a way to make him thirsty. How to make the public thirsty has been among the puzzling problems in the development of public health from the time that it went upon a rational and scientific basis. The only solution to the problem ever suggested or discovered is *health education*. No other means has been found to arouse this essential popular thirst. But that one has had a somewhat amazing success, until today we find it a leading objective among the activities of professional, social and educational groups in a community.

Referring again to the Economic Security Act, we hear the undoubted voice of a health minded populace speaking its approval of the appropriations of large sums to the Federal Public Health Service and to the health work of the Children's Bureau. No better proof could be forthcoming of the effective educational work pushed forward during the decades just past than the fact that from its first reading until its stormy passage no debate or challenge arose as to the wisdom of these two appropriations included in the provisions of the Act.

But to stop on this note of satisfaction with our achievements to date along the line of health security would be to mislead you completely as to the objective of this paper. While honesty requires acknowledgment of progress actually made, equal candor obliges us to admit that we are still lamentably far from the goal of possible achievement.

I will not bore you with figures to show our national penuriousness in the support of our local, state and federal public health services. Suffice it to say that in only one or two small corners of this country is there to be found an adequate public health budget. For the most part our towns and cities and states are spending from one-third to one-half the sums which experience has taught should be expended if our communities are to profit fully from the application of the principles of preventive medicine already known and ready to be put into operation. That is not a creditable showing for

a country that professes a vital interest in economic security, of which health security constitutes one of the most significant factors. Our business today is to stop wrangling over theories and to put facts to work. Whatever brilliant solution of the sick care problem awaits sedimentation in the minds of medical economists, preventive medicine has already crystallized out of our social experience a procedure which, now used with only fractional efficiency, is capable of development into the largest contributor to health security.

Take a single example. Suppose that tomorrow the number of public health nurses in this country were doubled, the result in early diagnosis of disease, in early treatment with quicker cure, in saving of lost time and the expense of illness, would be well-nigh incalculable.

Should the medical profession look with apprehension on such a suggestion let me state that theirs would be the chief profit. The nurse does not treat, she discovers. Her duty is to get patient and doctor into contact. Delay in this procedure is a major cause of health insecurity, eliminating such delay is the biggest step forward in health security.

Many other illustrations come to mind. A nearly adequate tuberculosis program reduced the death rate from that disease in Cattaraugus County last year to 18.3 in contrast to a national rate of 57. A well advanced venereal disease control program in Sweden has cut syphilis to one-twelfth of its prevalence in 1919, and brought it under practical public health control.

Without question the way of improved health security lies in large part, as it has in the past, along the path of more effective preventive medical work. To this end the medical profession will contribute an ever deepening interest in health with no sacrifice of their skilled ability in the treatment of disease. Methods of teaching are being developed in the medical schools to insure this indispensable objective. The public health service with increased resources and better trained personnel will make a larger contribution. A sanely educated public will co-operate more nearly to the needful degree. By all these means a brighter outlook is assured for the future just so far as prevention can contribute to the objective.

But this is only one side of the picture. We will always have sickness. Although test tube reproduction seems just around the corner, man will still be born of woman for a great many generations to come. Death comes to each and every one of us in our appointed time. Appendices will continue to disturb our peaceful lives. Strange aberrations of our endocrines, hormones and the vital fluids of our bodies are not destined to desert us in any visible future. And firearms, automobiles and aeroplanes will increasingly work their will on our fragile bones. We must have doctors and we must pay them enough so that they can survive to care for us in trouble.

One effect of depression and reduced incomes is an immediate tendency to ignore doctors' bills. If

our automobile breaks down and needs a new rear axle it is ordered at once and paid for on the same basis. If we get some wires crossed in our own insides we first try to postpone having them adjusted which is foolish and ultimately expensive. Secondly we go to the doctor when matters get too bad and run up perhaps a considerable account. There being no written contract, this bill waits and too often is permanently set aside. From our double delay there result health insecurity for ourselves and notable economic insecurity for the physician.

In an attempt to remedy this maladjustment nothing could be more natural than for the sociologist to turn for relief to the well-tested principle of insurance. At first thought such a course would seem a dependable way out for both parties concerned. By tradition and training however the doctor instinctively shuns regimentation. He is an individualist to a greater extent than most professional people who work naturally in teams or organizations. There is a sacrosanct relationship between him and his patient which is only approximated by that of the clergyman or the lawyer. And there is a great deal to be said for the social as well as the professional value of such relationship. Hence the suggestion of health insurance has had hard sledding with the medical profession as represented by organized medicine.

There is a further difficulty that arises in attempting an equitable solution of the health security problem along insurance lines. It lies in the difficulty of any wide application of the plan especially in this country. One evidence of this appears in the exclusion from the proposal of agricultural laborers and domestic servants, certainly two low paid classes who might naturally benefit by this form of insurance. It gives a flavor of class legislation to the scheme which is not wholly in keeping with our American instincts. Furthermore the limits of income between which health insurance should be applied is a controversial question. What is indigency? Below what income level is all payment impossible on a small insurance premium basis? Is there a determinable upper limit above which a private physician should expect reimbursement for his services at rates current in a given community?

It is a serious mistake to accuse the medical profession of selfish interference with the public welfare when it raises such questions and others in an honest effort to study the community's best interests as well as its own. If an emergency in health security really existed as claimed by some it would be another matter. I have indicated that neither by increased death rate nor by the prevalence of uncontrolled epidemics can a state of true emergency be declared in existence. This does not deny the chronic need for more adequate care of the sick which must be squarely faced both professionally and socially and met by some new plan or plans arrived at as the result of calm and dispassionate consideration of the many puzzling factors involved.

One can only guess at the nature of such plans

No single solution of the problems spread over the vast area of our great country is likely. Much more probable is the suggestion that a number of workable programs will develop each perhaps the most effective for the particular region in which it operates. For example in a small district in Oklahoma the co-operative system of community living has been extended to include medical care. Here a well-equipped hospital has been built with common funds and all members of the co-operative group are entitled to full medical care by skilled physicians who in turn receive adequate remuneration for their services.

Group practice is another of the procedures which has evidently become a permanent settler among accepted projects for the application of expert medical care at an expense within the limits of more modest incomes. The hospital insurance program while not growing with anticipated rapidity has also taken an apparently useful position as a further provision toward the assurance of health security.

District and state medical societies have undertaken with energy and enthusiasm experiments in the distribution of medical care which bid fair to solve some of the problems of reaching more effectively hitherto neglected groups in their respective communities.

Of the plan to pay the doctors bill through the medium of extended credit, I personally do not hold in high opinion. Apparently the American Medical Association is watching this experiment with interest and has not to my knowledge opposed it seriously. On the other hand to me it seems a rather frail and not particularly desirable procedure. The tendency to postpone payments run up hills and hays on the installment plan is too widespread among our American people. Extended credit was certainly one of the reasons for the grim disaster of 1929. I believe it is out of keeping with what should be our economic ideals to promote health security on a deferred payment basis.

Two years ago at Kansas City I read a paper on a topic allied to that with which the present one deals. At that time the depression was still deepening and the questions of adequate care of the sick, and adequate remuneration for the suffering medical profession were even more acute than they are today. To me there then seemed no way out save through federal aid in the direction of health insurance. Today I am largely of the opposite opinion. In fact, it is my definite feeling that federal compulsory health insurance is an increasingly remote probability. I am inclined to the belief that the social workers are not quite so clear in their minds as to just what is best for this country as they were then. I am further strongly of the opinion that the medical profession has been effectively shaken out of its laissez faire attitude toward the problem of inadequate distribution of medical care. Both agree that there is something wrong but both are now aware that the disability is of a chronic nature amenable to vast improvement by patient and time-

consuming methods of treatment but not likely to be curable by means of any single panacea much less by hasty and ill considered surgical operation

In summary, then, health security depends on three things, scientific medical knowledge both curative and preventive, financial ability to purchase it, both on the part of individuals and communities, a health-minded public with wisdom enough to make the purchase. These are all abstractions and cannot be brought about by legislation. Legal enactments will be needed to protect us from those who through misguidance or viciousness jeopardize their neighbors safety, but in the final reckoning health security will come not through the enactment of laws but through the cumulative effect on all classes of an intensively prosecuted program of health education

MISCELLANY

CONNECTICUT NEWS ITEMS

The State Department of Health on May 22, 1936, announced the appointment of a public health dentist, a librarian and an assistant mental hygienist. These three appointments represent additions to the department, two of the positions being new ones made possible by funds granted Connecticut under the Social Security Act for expansion of health services

Dr Franklin M Erlenbach of Boston, graduate of Tufts College Dental School and the Harvard School of Public Health, takes the new position of Chief of the Division of Mouth Hygiene in the Bureau of Child Hygiene. Since the completion of his training Dr Erlenbach has been an instructor at Tufts College Dental School, staff dental surgeon at the Brookline Contagious Hospital, a member of the Staff of the Brookline Dental Clinic and the Middlesex County (Mass.) Dental Clinic, and chief of the dental clinic at the Forsyth Dental Infirmary

Miss Anna Katherine Tobias, formerly of West Hartford, a graduate of Randolph Macon Woman's College at Lynchburg, Va., and the School of Library Science of Simmons College becomes librarian of the department. She is the daughter of Dr Henry W Tobias, formerly clinical director of the United States Veterans Hospital in Newington

Miss Helen S Peterson of New York City, graduate of Oberlin College and the Smith College School of Social Work, is appointed to the new position of assistant mental hygienist in the Bureau of Mental Hygiene. Miss Peterson comes to Connecticut after serving as case worker for the Institute of Family Service of the Charity Organization Society, New York City

Dr Stanley H Oshorn, Health Commissioner, also announced that Dr Henry P Talbot, who has been studying at the Harvard School of Public Health for one year, will return June 1 as director of the Bureau of Venereal Diseases, a position from which he had leave of absence. Dr Alfred L Burgdorf, acting director of this bureau, will be transferred

to the Bureau of Preventable Diseases to fill a vacancy existing there

Dr Charles C Beach, one of Hartford's "grand old men" and for many years prominent in medical, business and social affairs in that city, observed his eightieth birthday anniversary on May 19 1936. He is enjoying good health and still delights in attending gatherings of the Hartford Medical Society and of the Medical Masonic Club of Hartford

Dr M Vincent Mikolajinis of Hartford was recently reelected President of the Connecticut Lithuanian College and Professional Association, an organization of college graduates of Lithuanian extraction. Among the other officers elected was Dr John S Staneslow of Waterbury, treasurer

A decision in favor of Dr Emerson L Stone, New Haven obstetrician and gynecologist in a suit brought by Mrs Gertrude Green of New Haven, alleging negligent medical treatment following the birth of her child on August 4, 1931, was sustained May 19, 1936, by the Supreme Court of Errors. In the original trial of the action Mrs Green obtained a verdict of \$2,250 damages which the trial court set aside. In the present case, tried before a New Haven County jury and Superior Court Judge Frederick M Peasley now retired, a jury returned for Dr Stone a verdict which was accepted. Justice John W Banks wrote the opinion, holding there was no error in Judge Peasley's charge to the jury

The Hartford County Mental Hygiene Society held its annual meeting and dinner in Hartford on Tuesday evening, May 19, 1936. Dr Charles W Stephenson of Hartford, retiring president of the society, presided at the meeting attended by more than fifty persons. Among the newly elected directors was Dr John A Wentworth of Hartford

Dr John A P Millet, New York psychiatrist and neurologist, was the guest speaker. Calling psychiatry the "Cinderella of medical sciences" Dr Millet said, "Psychiatry is playing an increasingly large part in the realm of criminology, but there are still too many people who consider it simpler to lop off a criminal's head or to imprison him for life than it is to treat him as a mental case. While in prison many criminals are affected by their punishment only in that they experience a hardening of their already strong antisocial feelings. How much more intelligent it would be for us to exchange social therapy for social punishment."

"The psychiatrist has the aspirations of a therapist and the hope of the public. As a science psychiatry has extended its operations until there is almost no human sphere in which it does not make itself felt. But it has a colossal obstacle to overcome—now, as always, the public feels that there is some great stigma attached to a psychogenic ailment. This feeling must be changed and it will be changed—by education

Further than that, progress in this science must come through the psychiatrist's realization of the

limitations of his own present knowledge combined with an overpowering enthusiasm to examine new things in the realm of psychiatry. Psychiatrists must keep an open mind, must master the technique of exact diagnosis and must keep abreast of all developments in psychotherapy.

Reorganization of the Hartford Health Department to provide for the addition of several bureaus and the expansion of personnel that will mean a definite increase in budgeting allotment was proposed in a plan submitted at a meeting of the Board of Health Commissioners on May 20, 1936 by Dr. Robert V. Boyce, President of the Board. The Health Board voted to send copies of the plan to His Honor Thomas J. Spellacy, Mayor of Hartford. The salient features of the plan are as follows:

(1) Return of the Isolation Hospital now under the jurisdiction of the Welfare Board to the Health Department where it rightfully belongs. Such a change would require a change in the city charter. The Chairman of the Welfare Commissioners Hospital Committee objects to this change on the ground of increased expense.

(2) Establishment of a Bureau of Child Hygiene headed by a part-time physician and with a supervisor preferably a woman to act as executive director. At the present time the pre-school hygiene and maternal hygiene is being carried on by the Visiting Nurse Association. Although their work is efficient it does not meet the need as it exists in a city the size of Hartford.

(3) Establishment of a Division of Child Mental Hygiene or Child Psychology and possibly the development of an added Adult Mental Hygiene Division. This division to be directed by a full-time physician with case workers added as the increasing work shall demand. It is believed that such a provision will aid greatly in relieving the rapidly growing juvenile delinquency which is plaguing many social agencies.

(4) Addition of one more sanitary inspector and return of the food and poultry markets now under the Public Buildings Commission to the Health Department. These markets are believed to present a real health menace and under proposed change could be operated as a health unit whereby such complaints such as the sale of smothered poultry that previously existed would be terminated at their source.

(5) Change of City Charter to provide that the secretary of the Health Board be Registrar of Vital Statistics and for the addition of another assistant registrar.

(6) Appointment of a full-time physician in charge of the Venereal Disease Division of the Department and appointment of at least one more nurse. These additions are necessary to carry out a venereal disease program such as has been outlined by an advisory committee to the United States Public Health Service.

THE ONE HUNDRED AND FORTY-FOURTH ANNUAL MEETING OF THE CONNECTICUT STATE MEDICAL SOCIETY

The Connecticut State Medical Society convened at Hartford for its annual meeting on May 20 and 21, 1936. The entire program was one of the best ever afforded its members and the registration of 300 testified to the interest shown.

Officers elected were as follows:

President Daniel C. Patterson, Bridgeport

Vice-Presidents Thacher W. Worthen, Hartford
Hugh B. Campbell, Norwich

Administrative Secretary Creighton Barker, New Haven

Legislative Secretary Charles W. Comfort, Jr., New Haven

Secretary on Scientific Work Stanley B. Weld, Hartford

Treasurer James R. Miller, Hartford

The principal innovation in the administrative personnel passed by the House of Delegates at its session on the second day of the meeting divided the work of the former secretary into three parts, viz., administrative, legislative and scientific work. This resulted as a compromise following a move started a year ago to secure a full-time, non-member secretary in the interest of increased efficiency.

The Connecticut Society voted to abolish publication of its annual proceedings, a volume placed in the hands of each member almost since the Society was founded. In its place the Secretary on Scientific Work, among other duties, becomes the editor of a quarterly journal, this to serve as a record of the Society's activities and at the same time as a means of keeping its membership informed on matters of medical importance.

Upon recommendation of the Council the House of Delegates voted to discharge the delegates to the New England Medical Council whose terms have not expired and to elect no further delegates until required by the New England Medical Council having been discontinued. The House of Delegates also voted to discharge the Committee on Emergency Unemployment Medical Relief, there being no further need for such a committee.

Colonel Charles Franklin Craig, United States Army, Retired Professor of Tropical Medicine, Tulane University of Louisiana School of Medicine, was elected an Honorary Member of the State Medical Society.

The Council recommended to the House of Delegates and the House voted the adoption of the recommendations contained in the Report of the Committee on Medical Economics as affirmed procedure for the State Society, viz:

(1) that the study of medical practice in the State as a fact-finding survey be continued to completion.

(2) that in view of the fact that local factors influence the program for the care of the indigent, those matters be referred to local medical organiza-

tions, where they appear properly to belong for adjustment, and that the State Society withdraw from further attempts to co-ordinate or standardize procedure throughout the State, with the reaffirming of the policy that patients should be allowed the free choice of physicians

One of the most important actions taken by the House of Delegates was the following vote, viz, That in accordance with the recommendation contained in the Report of the Committee on Public Health, the Committee on Public Health be charged with the formulation of a detailed specific directive for the handling of accident cases to prevent additional further injury from the process of transportation, to include standard fracture equipment for all ambulances or vehicles regularly used as such, that such directive be submitted for approval by the Council, that, upon approval by the Council, such directive be referred to the Committee on Public Policy and Legislation for transmittal in the name of the Society, to police, press, and other agencies, in such manner as will make most effective the sense of this recommendation

The House of Delegates voted to request the Council to consider the draft of "Standing Orders and Policies for Public Health Nurses", prepared by the State Department of Health and presented through the Committee on Public Health and to authorize the Council, when it considers such approval may be given to approve, officially in the name of the Connecticut State Medical Society, said "Standing Orders and Policies for Public Health Nurses", and to transmit such approval to the State Commissioner of Health for use therewith

During the first forenoon of the Annual Meeting, clinics were held at the St Francis Hospital, the Municipal Hospital, and the Cedarcrest Sanatorium, and during the second forenoon at the Hartford Hospital, the Neuro Psychiatric Institute of the Hartford Retreat, and the Newington Home for Crippled Children. These clinics were very well attended

The afternoon programs comprised the following papers

Activities of the State Department of Health in Carrying Out Provisions of the Social Security Act
Stanley H. Osborn, M.D., Commissioner, State Department of Health, Hartford

Activities of the Committee on Public Health of the State Medical Society in Relation to the Social Security Act
Joseph I. Linde, M.D., Chairman, Committee on Public Health

Surgical Treatment of Craniocerebral Injuries
Richard C. Buckley, M.D., Hartford

Injection Treatment of Hernia
Daniel C. Patterson, M.D., Bridgeport

President's Address. Expert Medical Testimony
Thomas P. Murdock, M.D., Meriden

*This paper created considerable discussion in the lay press comment being both favorable and unfavorable

Clinical Aspects of Thyroid Disease. Adrian S. Taylor, M.D., Clifton Springs, N.Y.

The Limitations of Pneumothorax Therapy in Lobar Pneumonia
Francis G. Blake, M.D., Sterling Professor of Medicine, Yale University, New Haven

Early Motion in Fracture Treatment. Merrill K. Lindsay, M.D., Associate Professor of Orthopedic Surgery, Yale University, New Haven

At the Section on Radiology two papers were presented

Results of Comparative Doses on Human Tumors using Fever and Roentgen Irradiation, by Stafford L. Warren, M.D., Assistant Professor of Radiology, University of Rochester, N.Y.

Roentgenologic Study of the Appendix, by Hugh Wilson, M.D., Assistant Professor of Radiology, Yale University School of Medicine, New Haven

The Section on Obstetrics and Gynecology presented Emil Novak, M.D., Baltimore, on The Use and Abuse of Endocrinology in Gynecology

At the Section on Neurology and Psychiatry Arthur P. Noyes, M.D., Superintendent, State Hospital for Mental Diseases, Howard, R.I., spoke on Relationship of Psychiatry to Medicine

At the Section on Dermatology and Syphilology two papers were presented

Pustular Bacterids of the Hands and Feet, George C. Andrews, M.D., Assistant Clinical Professor of Dermatology and Syphilology, College of Physicians and Surgeons, Columbia University, N.Y., and Occupational Dermatoses, Harry S. Reynolds, M.D., Hartford

The Hezekiah Beardsley Pediatric Club presented its scientific program on the afternoon of May 20 at the Municipal Hospital

At the Section on Eye, Ear, Nose and Throat two papers were presented

Clinical Considerations of Ocular Fatigue
Conrad Berens, M.D., New York City

Review of Operative Technique in Nose and Throat Surgery
E. Ross Faulkner, M.D., New York City

On the evening of May 20 the Hartford Medical Society and Hartford County Medical Association were hosts to the guests and members at an Entertainment and Smoker. The following evening the Annual Dinner was held at the Hartford Club. On this occasion Dr. Arthur B. Landry acted as toast master. Remarks were made by the retiring president Dr. Thomas P. Murdock, and by the newly elected president, Dr. Daniel C. Patterson. George Ross Wells, Ph.D., Professor of Psychology, Hartford Theological Seminary, spoke on "Is Civilization Getting Us Anywhere?"

Members who so desired enjoyed the golf facilities afforded by the Wampanoag and Hartford Golf Clubs. The Woman's Medical Society of Connecticut met for its annual luncheon at the Hartford Club on Wednesday, May 20

THE MASSACHUSETTS PUBLIC HEALTH
ASSOCIATIONREPORT OF THE COMMITTEE ON THE RELATIONSHIP OF
BOARDS OF HEALTH TO THE MEDICAL PROFESSION

The committee of five appointed by the President to recommend to the Executive Committee of the Massachusetts Association of Boards of Health as to the duties, programs and responsibilities of Boards of Health and the relationship of the same to the medical profession submits the following report:

Boards of Health are charged with the responsibility of preventing disease and promoting the health of the people within their local jurisdiction. Specific powers and duties are delegated to them by state laws and they are empowered to adopt and to enforce reasonable local rules and regulations. Their work is supported by taxation and they are the servants of the people.

The advancement of the science of health particularly in the fields of bacteriology and immunology and also the demonstration of what may be accomplished in health promotion by the diffusion of health information among the people has during recent years greatly expanded the scope of public health activities. Traditionally Boards of Health have been thought of chiefly as exercising broad police powers through the power to license to abate nuisances to condemn contaminated property and to order personal or property quarantine. While environmental sanitation and the other phases of work mentioned are still important the recent trend has tended to bring health departments and their personnel more directly in contact with individuals, or groups of persons for prophylactic treatments, diagnostic advice and education through clinics by home visits or in other ways. Properly administered, such services are clearly preventive in nature and in no way infringe upon private medical practice. No line can be drawn as to what persons are entitled to health protection and health services any more than in the case of police protection or fire protection. The taxpayers pay for health work and all alike are entitled to the benefits of milk control work, laboratory diagnosis or tuberculosis diagnostic clinics.

Boards of Health do not and should not, generally treat disease or render medical services beyond diagnosis, or protection against certain epidemic diseases. We believe and experience supports the belief that Board of Health activities make the people more aware of health and of the value of medical services resulting in many more persons seeking medical advice, treatment and prophylaxis privately than would be the case in the absence of such services. It should be the aim of Boards of Health and their agents to recommend and encourage individuals to consult their own physicians in all cases of sickness and also for prophylactic treatment and health examinations.

There should be no conflict between Boards of Health or their agents and private medical practice. Boards are not interested in administering to the

sick. They are interested in protecting the community from preventable diseases and spreading the gospel of health. They do not provide preventive services to those who are receiving them from the family physician.

Be it therefore resolved:

- 1 That it is the responsibility and duty of Boards of Health to employ professionally qualified personnel to administer public health work and that such persons should be free from political influence or interference.
- 2 That the basic activities of Boards of Health include:
 - (e) The control of communicable diseases by enforcing the provisions for prompt reporting of cases of diseases declared dangerous to the public health by isolation and quarantine by providing for immunization against certain specific diseases by providing for the diagnosis and sanatorium treatment of tuberculosis and by any and all other measures that are lawful and effective.
 - (h) The promotion of maternal and child health by adequate provision for maternal and infant care and preschool and school child health.
 - (c) Sanitation including the protection of the water and milk supplies and other foods and responsibility for other environmental sanitary measures and the proper disposal of sewage and other wastes.
 - (d) Laboratory services for aid in diagnosis and the testing of milk, water food and other commodities that may affect the public health.
 - (e) The recording and analysis of vital statistics.
 - (f) Other recognized practices including health education, epidemiological studies and research.
- 3 That the services and resources of Boards of Health are available to all citizens within the legal jurisdiction of a given Board.
- 4 That it should be the responsibility of the Boards of Health to encourage the medical profession to a greater participation in the practice of preventive medicine and to inform the general public of the availability of the medical profession for this type of service.
- 5 Finally be it resolved that to further these mutual interests of Health Departments and physicians it is recommended that the Massachusetts Medical Society be invited to appoint a committee or delegates to meet with a committee of the Massachusetts Association of Boards of Health to discuss from time to time matters of joint interest and concern.

DR. WILLIAM O. HEWITT *Chairman*
DR. CHARLES F. WILKINSKY
DR. ERNEST M. MORRIS,
MR. JOHN J. McGRATH
PROFESSOR CURTIS M. HILLIARD

The Association voted to accept this report at its annual meeting, January 30, 1936

At the same meeting the Association changed its name to "The Massachusetts Public Health Association"

DR HODGKINS ADDRESSES THE MASSACHUSETTS SOCIETY OF EXAMINING PHYSICIANS

Dr Edward M Hodgkins, Assistant Professor of Surgery at Tufts College Medical School, read a paper at the annual meeting of the Massachusetts Society of Examining Physicians, May 27 entitled "Direct Inguinal Hernia in Relation to Industrial Accidents"

PROMOTIONS IN THE HARVARD FACULTY

The following promotions in the Harvard faculty have been announced Dr Gordon W Allport, from assistant professor to associate professor of psychology Dr Philip Drinker, from associate professor to professor of industrial hygiene, and Jacob P Den Hartog, from assistant professor to associate professor of applied mechanics—*Science*, May 29, 1936

U S COURT FINES AND REPRIMANDS MANUFACTURER OF LOW-STRENGTH DISINFECTANT FOR HOSPITAL USE

The Century Chemical Products Co., Detroit, Mich, was fined \$300 and rebuked by the Court on May 15 in an action under the Federal Insecticide Act The Food and Drug Administration, in comment on the action, says the company's product, known as "De-Germ," was offered as a disinfectant and germicide for use in theatres, hospitals, schools and other public places It was tested by government bacteriologists and found to be ineffective against some of the commoner forms of bacteria, even when used full strength. Analysis showed it to be a weak solution of formaldehyde (1½ per cent), phenolic substances, soap and perfume materials in water (96 per cent)—*Bulletin*, U S Department of Agriculture

SUMMER CAMPS

For four years the Boston Health League has issued a mimeographed bulletin concerned with summer camps This first pamphlet contained two sections Safeguards from Communicable Disease and Food Economies

In 1935, the material was completely revised and amplified, and with a few changes the bulletin for 1936 has been issued

The Committee wishes to stress the importance of adequately trained personnel, and a well planned program allowing for participation by director, campers and counselors, which will develop in each camper an appreciation of out-door living, and which is sufficiently flexible to permit individual taste and capacities to be developed Fatigue may contribute to ill health as much as malnutrition A

program not too competitive in character will add to the value of camp life

The essential features slightly abbreviated are as follows

I EQUIPMENT

- 1 Tentage or housing for sleeping quarters must give proper protection against the weather, and insects, if necessary It is recommended that each sleeping unit accommodate as few campers as is practicable Every child should have a single bed An average of forty or more square feet of floor space should be allowed for each individual camper
- 2 An infirmary should be provided with adequate first aid equipment available at all times
- 3 Necessary fire fighting equipment should be provided Equipment will depend somewhat upon conditions in each camp, but in general
 - (a) Approved fire extinguishers in sufficient number should be provided for each building, special attention being given to kitchens and other places where cooking appliances are used
 - (b) Nested buckets should be located outside buildings and in wooded sections adjacent to the covered barrels
 - (c) Brooms, shovels and similar equipment should be available to combat brush and grass fires These should be placed in separate enclosures for quick and convenient use, properly marked for fire use only
 - (d) In the case of large camps, one or more 25 to 40 gallon hand drawn chemical extinguishers would be a valuable asset to the equipment It is sometimes possible to provide a greater degree of protection where a pond or river is close by where an electric or gasoline driven pump may be installed with piping laid for fire protection service This system could also be a part of the domestic water supply
 - (e) In addition to equipment, it is most important that the supervisors should hold periodic fire drills for the safety of the children

II SANITATION

- 1 The water supply for drinking, culinary and personal cleanliness purposes should be certified as safe by the local or state department of health before camp opens, and should be tested at adequate intervals
- 2 Common drinking cups should never be used Bubbler fountains should be installed in the main building used for common purposes and on the grounds where the children may reach them easily
- 3 Toilet facilities should be adequate,—one unit for every ten persons They should afford in

dividual privacy. The latrine pits should be fly tight, and handwashing facilities should be provided at the latrines.

4. Provision should be made for hot baths, tub or shower, and each camper should be required to have at least one hot bath weekly.

III. STAFF AND LEADERSHIP

The staff should include:

1. A camp director of mature judgment, who is able to take full administration and responsibility for the program of the camp.
2. At least one adult counselor for every ten children—the ideal is a counselor for every three or four.
3. A registered nurse and arrangements should be made with a physician in the neighborhood for services in cases of emergency.
4. A dietitian.
5. A waterfront director who is an American Red Cross Examiner if there are waterfront facilities.

The camp staff should be well balanced in abilities and personalities having a knowledge of modern developments in education and child guidance as well as the ability to maintain standards of health, food and safety.

IV. FOOD

1. In order that food money may be used to best advantage it is urged that a trained dietitian be in charge. If this is impossible a student counselor specializing in home economics will be very helpful.
2. Each child should have:
 - Oat quart of pasteurized or homed milk daily.
 - Whole-grained cooked cereal daily.
 - Whole-grained bread at every meal.
 - Vegetables twice daily, green or yellow are least expensive and a raw clean vegetable should be served once a day.
 - Fruit twice a day including an orange, tomato (fresh or canned), grapefruit, apple or pineapple.
 - Meat or fish and an egg daily.
 - Butter should be served on the table; other fats may be used in cooking.
 - Molasses, brown sugar and fruits may well take the place of some white sugar.

V. DINING ROOM FACILITIES

1. Small tables should be used preferably seating not more than eight.
2. Ample time should be allowed for meals, and children encouraged to learn good eating habits.
3. Method of serving food should insure equal and prompt distribution.

VI. REST

The fatigued child cannot derive proper benefit from camp. Overexcited children are also fatigued children. In competitive events do not permit rivalry to become so keen that children are spurred on to too great activity for their individual strengths.

Activities should stop and there should be a half hour quiet period before dinner and again before supper with a rest of an hour directly after the noon meal when every child is required to lie on his cot.

VII. SWIMMING

The waterfront staff should include:

1. A waterfront director who is an American Red Cross Examiner at least twenty years of age who is in charge of all swimming, boating and canoeing.
2. There should be an American Red Cross Senior Life Saver in charge of each class of swimmers. If there are more than ten swimmers in a class there should be an additional American Red Cross Senior or Junior Life Saver to help supervise each additional ten swimmers in each class.
3. There should be two American Red Cross Life Savers, a Senior and Junior who are in each of two boats that control the outer area during the swimming periods and an experienced oarsman to handle the oars. The lifesaver sits in the stern of the boat with a bamboo pole—8 feet long with a canvas strap (double thickness 2" made from 4" canvas)—within reach and keeps constant watch over the swimming area.
4. Each person should be classed according to experience and ability in swimming and should be kept within definitely marked areas according to classification.
5. These regulations with the exception of number three apply when swimming is in a pool as well.

VIII. BOATING AND CANOEING

1. All boating and canoeing should be in charge of an American Red Cross Examiner at least twenty years of age. He or she should be an experienced boatsman or canoeist, and may be the waterfront director.
2. An experienced oarsman should be in every boat, and an experienced canoeist in every canoe.
3. A person must not be allowed to have the use of a canoe without passing the following requirements:
 - Be a swimmer, one who can jump in the water over his depth, tread water, swim or float on back and who is able to swim 100 yards.*

*These requirements should be passed in an interview.

4 Canoe requirements

Tip canoe over when dressed, turn canoe upright, get in and handpaddle to shore *

5 Boats and canoes should be used only with permission of the person in charge, and should be tagged in and out. There should be definite boundaries easily seen and reached by canoes and boats

6 Lifesaving equipment should be adequate, and kept in perfect order and be placed where it is immediately available. Small life preservers on a long rope (60 feet), which can be thrown a distance, are essential. They should be placed in boats and hung in conspicuous places on the shore and floats

IX PHYSICAL EXAMINATIONS

1 Each member of the staff should pass satisfactorily a physical examination, not more than one week before entering camp

2 Prospective food handlers, in addition to the regular physical examination, should be examined to detect possible typhoid carriers

3 Each camper should pass satisfactorily a physical examination, not more than one week before entering camp. Evidence of a physical examination in the form of a health certificate should be presented. It is suggested that camps might adopt blanks. Blanks may be secured from the Purchasing Bureau, Boston Council of Social Agencies, for \$1.00 for one hundred copies, \$3.50 for five hundred and \$6.00 for one thousand copies

BIBLIOGRAPHY

There are many helpful books on camping and all its phases. Below are listed just a few

Camping and Character by Hedley S. Dimock and Charles E. Hendry. Associated Press, N. Y. 1929

Camping and Woodcraft by Horace Kephart, Macmillan Company, N. Y. 1931

Camp and Camping by Eugene H. Lehman, American Sports Publishing Company 1930

Creative Camping by Joshua Lieberman, Association Press, N. Y. 1931

Camping and Education by Bernard S. Mason, McCall Company, N. Y. 1930

Education in the Summer Camp by Lloyd Burgess Sharp, Teachers College Contributions to Education No. 390. Teachers College, Columbia University, 1930

Current Problems in Camp Leadership—A Workbook for Camp Counselors and Directors. Edited by Jackson R. Sharman, Marjorie Hillas and David K. Brace. Ann Arbor Press, 1934. (Contains an extensive bibliography.)

Character Education in the Summer Camp—Setting Standards in the Summer Camp. Asso-

ciation Press, 347 Madison Avenue, N. Y. 75¢. Material compiled at the 1934 Institute of the Chicago Camp Association.

CORRESPONDENCE

DOCTORS ON RELIEF

Editor, *New England Journal of Medicine*,

In the May 14 edition of *The New England Journal of Medicine* there were some statistics giving the number of doctors and attorneys on relief which I understood to be in the country. If my understanding is correct I believe that the figures given are far from correct.

Shortly before Christmas I obtained a list of doctors on the county or relief for this county. There were fifty-seven. About half were registered in this state. Five were members of the County Medical Association. On eight of them I did not have sufficient data to determine whether they had ever been registered anywhere. Twenty-five per cent were women. It was chiefly in the group of women where evidence of registration anywhere was found.

I understand that the number of attorneys in this county was at that time over a thousand but do not have the figures.

Yours sincerely,

LLOYD A. BURGESS, M.D.

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

535 North Dearborn Street, Chicago, Illinois,
May 29, 1936

The New England Journal of Medicine,

In addition to the articles enumerated in our letter of May 1 the following have been accepted:
Billhuber Knoll Corporation

Hypodermic Tablets of Metrazol 1½ grains

Hospital Liquids Inc.

Ringer's Solution

Dextrose 5% in Distilled Water

Dextrose 5% in Physiologic Solution of Sodium Chloride

Dextrose 10% in Distilled Water

Dextrose 10% in Physiologic Solution of Sodium Chloride

Dextrose 25% in Distilled Water

*These requirements should be passed in shallow water

Lederle Laboratories Inc.

Refined Alum Precipitated Tetanus Toxoid—
Lederle

Parke Davis & Co

Compressed Tablets Sal Ethyl Carbonate with
Phenacetin

The following articles have been accepted for inclusion in the List of Articles and Brands Accepted by the Council But Not Described in N.N.R. (New and Nonofficial Remedies 1935 p 445)

Hospital Liquids Inc.

Physiologic Solution of Sodium Chloride

Lederle Laboratories Inc.

Smallpox Vaccine (Lederle) (Preserved with Brilliant Green)

United States Standard Products Co

Magnesium Sulphate 25% in 5 cc. Ampula

Yours sincerely

PAUL NICHOLAS LEECH Secretary

Council on Pharmacy and Chemistry

RECENT DEATHS

BLACK—DENNIS LEO BLACK M.D. a member of the Surgical Staff of the Veterans Administration 600 Washington Street, Boston died suddenly at his office June 4 1936 Dr Black was born in 1882 and graduated from the Dartmouth Medical School in 1910

He served in the Medical Department throughout the World War and was appointed to the Veterans Administration Service immediately after his discharge in 1919

Dr Black is survived by his widow who he left at their home in Methuen and a brother Dr James Black of Nashua New Hampshire

SISSON—MITCHELL SISSON M.D. of Brookline whose office was at 468 Commonwealth Avenue Boston, died June 1 1936

Dr Sisson was born in 1887 in East Boston and graduated from the Harvard Medical School in 1913 He had served as school physician for the East Boston School district since 1920

He was a Fellow of the Massachusetts Medical Society and the American Medical Association His widow Mrs Hattie C Sisson and a son Harrison Sisson, survive him.

GUIBORD—ALBERTA SYLVIA BOOMHOWER GUIBORD M.D. of 1932 Beacon Street Waban died May 27 1936

Dr Guibord was born in 1873 She graduated from the Boston University School of Medicine in 1899 and was a Fellow of the Massachusetts Medical Society and the American Medical Association

NOTICES

1936 GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The Ninth Annual Graduate Fortnight will be held October 19 to 31 and will be devoted to a consideration of Trauma Occupational Diseases and Hazards

Twenty three important hospitals of the City will present co-ordinated afternoon clinics and clinical demonstrations. At the evening meetings prominent clinicians from various parts of the country who are recognized authorities in their special lines of work will discuss various aspects of the general subject.

A comprehensive exhibit of books pathological and research material apparatus for resuscitation and other first aid appliances will be assembled Demonstrations will be held at regular intervals.

Some of the features to be presented at the meetings, in the clinics and in the exhibit will be First Aid in Industry in the home and on the highway

Accidents and their management

Resuscitation

Shock and hemorrhage

Hazards in athletics

General principles of fracture treatment

Fractures of the extremities

Injuries of the head spine abdomen chest and genito-urinary systems

Hand injuries

Burns—thermal electrical radiant and chemical

Medicolegal aspects of trauma and disability

War injuries and emergencies including—

Injuries caused by high explosives

Medical aspects of chemical warfare

Gas attack, gas defense

Carbon monoxide poisoning

Fatigue and noise in industry

Harmful conditions in industry

Occupational diseases

Occupational hazards

Industrial poisonings

Relation of trauma to disease

The medical profession is invited to attend

A complete program and registration blank may be secured by addressing Dr Frederick P Reynolds The New York Academy of Medicine, 2 East 103d Street New York City

LADIES HELPING HAND HOME FOR JEWISH CHILDREN

The Ladies Helping Hand Home for Jewish Children 35 Chestnut Hill Avenue Brighton desires to call attention to the continuance of its Health Program for undernourished Jewish children as announced in previous communications

The organization is equipped to care for those children who need Convalescent Care during their

recovery from operative procedures and severe illnesses

This program includes a definite schedule of medical care, rest, diet and recreation, under the supervision of our medical, nursing and consulting staffs

This service is intended for such worthy patients as may come within the above specifications

Applications may be procured by writing to the Ladies' Helping Hand Home for Jewish Children

Visits to our Home at any time will be cordially appreciated

REPORTS AND NOTICES OF MEETINGS

BOSTON HEALTH LEAGUE CORPORATION

There was a meeting of the Corporation of the Boston Health League on Thursday, May 21, at 12 30 o'clock Dr Bartol, President, presided, and representatives from the following agencies were present

Boston Dispensary
Boston Health Department
Boston Metropolitan Chapter, American Red Cross
Boston Tuberculosis Association
Community Federation of Boston
Community Health Association
Housing Association of Metropolitan Boston
Massachusetts Department of Public Health
Massachusetts General Hospital
Massachusetts Society for Mental Hygiene
Massachusetts Society for Social Hygiene
Metropolitan District, Massachusetts Dental Society
Suffolk District Medical Society
Women's Municipal League of Boston

Dr Bartol stated there was one item of business before the Corporation The Community Federation has requested that the Boston Council of Social Agencies, the Boston Health League and the Hospital Council of Boston give consideration to moving their offices to be adjacent to those occupied by the Community Federation of Boston At the Quarterly Meeting of the Council of Social Agencies on Tuesday, May 19, the following vote was passed "That the Council move to offices adjacent to those occupied by the Community Federation of Boston as soon as practicable" On motion duly made and seconded, it was

Resolved that the Health League also move to offices adjacent to those occupied by the Community Federation of Boston as soon as practicable

TREASURER'S REPORT

Dr Wadsworth reported that the Health League balance was \$1,249 after the bills were paid on May 1 He also stated that at the meeting of the Permanent Charity Fund Committee on May 7 the Committee voted to contribute \$500 for the coming year to the Boston Health League This reduces the annual contribution from the Permanent Charity Fund by \$500, and it will be necessary to ask the Allocating Committee for a special appropriation to make up this deficiency if the work of the Health League is not to be seriously curtailed during the rest of the year

The remainder of the meeting was devoted to committee reports

CANCER

The Educational Committee on Cancer of the Boston Health League was formed at the request of the Massachusetts State Health Department in 1930 to carry on the educational work for the city, and receives a small grant from the Department for this purpose

In the spring of 1935 the Division of Adult Hygiene, which is responsible for the state cancer program, asked this Committee if it would consider concentrating effort in one section of Boston, and by stimulating interest of local organizations in cancer control, arrange for talks on the subject by the practicing physicians of the community before these local organizations Hyde Park was selected as the district because it is a homogeneous unit of 24,000 population where the families are cared for in the main by the family physician On January 29 of this year, a general meeting was held in the Municipal Building in Hyde Park under the joint sponsorship of the Massachusetts State Department of Health, the Boston City Health Department and the Boston Health League As a direct result of this meeting two cancer talks were scheduled in Hyde Park, both given by local physicians In addition, members of the Educational Committee of the Health League spoke to two other organizations in Hyde Park

The Health League purchased a portable projector, and additional interest in cancer control has been stimulated by the showing of the delineascope film, "Fight Cancer with Knowledge," which was prepared by the American Society for the Control of Cancer This film is very simple, can be run off in a very short time and serves as a valuable adjunct to the talks by physicians One physician in Hyde Park thought so highly of the film that he showed it in his office for the benefit of groups of patients

Since October 1935, the Educational Committee on Cancer, of the Health League, has been directly responsible for eight talks These were given before women's groups in churches and settlement houses throughout the city, with Dr Shedden addressing the Men's Club of the Weston Baptist Church Literature on the subject of cancer control was distributed at these lectures and at the majority of them the delineascope film was shown

CHILD HEALTH

The activities of the Child Health Committee have fallen into two divisions this year (1) The Underprivileged Child Committee of the Kiwanis Club of Boston asked the Boston Health League to outline a health program to be undertaken by them and the matter was referred to the Child Health Committee. At a meeting on April 7 1936 it was decided that there were three objectives which would appeal to a committee of this character and which would fill a distinct need

- 1 This committee might adopt a few individual children who were tuberculosis contacts and be responsible for their care at Prendergast Preventorium
- 2 There are always individual children known to the Harvard Infantile Paralysis Commission who need more care than the Commission can furnish and these children might become the special charge of this committee
- 3 It is generally felt that there is insufficient care for cardiac children

Material regarding these three projects was submitted to the Kiwanis Club on May 8 and Dr. Sisson and Dr. Smith met with the Underprivileged Child Committee on Friday May 22, to discuss the matter further

(3) Summer Camps At a meeting of the Committee on April 22 regarding summer camps it was decided to revise slightly the material published last year. Interest in these summer camp pamphlets has grown to such an extent that 750 copies have been mimeographed. Morgan Memorial has ordered one hundred copies at five cents each to be distributed among their workers. At this meeting on April 22 the Committee stated that they considered that physical safeguards were the major concern of the Health League but that interest in summer camps had broadened beyond physical standards and it was voted to request the Boston Council of Social Agencies to form a committee on recreation or camping which would be representative of all groups engaged in running nonprofit camps and which would consider all sides of camping programs. At the meeting of the Executive Committee of the Council of Social Agencies on May 7 it was voted to accept this recommendation of the Health League and to form such an organization

At the meeting of the settlements on Wednesday May 20 Mr. Kingman, a member of this Committee presented the 1936 pamphlet and there was considerable discussion and interest. The settlement group wished to study these recommendations during the summer to find out whether they were practicable and it was planned to have a small committee which hopes to visit summer camps.

At the meeting of the Children's Division the same afternoon Miss Tracy presented the pamphlet and stated that the Health League offered this as

a guide but that it was realized every camp could not follow specifically all recommendations made. This material is intended as a guide to indicate whether camps in general are able to maintain proper physical standards

Copies of the pamphlet will be mailed to all organizations conducting summer camps. Members of the Health League Executive Committee of the Boston Council of Social Agencies and since its first publication in 1932 the Massachusetts Tuberculosis Association and the State Department of Health have used the pamphlet in helping to determine criteria in physical standards.

HEALTH EDUCATION

The Health Education Committee has been working upon two educational projects during the year. One of these was a series of food exhibits demonstrating elementary principles of nutrition. In addition to teaching nutrition, these exhibits demonstrated the importance of visual education in teaching health to the community. Enthusiastic cooperation in working out the plans has been given the committee by the City Health Department, the Department of Public Welfare, the nutrition workers of the voluntary agencies and the agencies housed in each health unit where the exhibits were displayed.

The first exhibit urged the importance of using the whole-grain product as a source of iron and vitamins and showed the cost of each cereal. This exhibit has been displayed in the Health Units in the West End, South Boston and Charlestown. In each unit a meeting of neighborhood people was held and was well attended. Miss Foster talked at these meetings.

On the planning and organization of the exhibits the Department of Health Education of the Boston Dispensary has spent a great amount of time and effort including the special service of a paid worker and it is hoped that the work may be continued under the service of a special worker. A great deal of material has been accumulated as a foundation for its continuance. The files of the Boston Health League contain photographs of the exhibits, plans drawn to scale and copies of materials distributed and the furnishings have been preserved so far as possible.

As another means of advancing the education of the public in nutrition the Chairman of the Health Education Committee conferred with the teacher of Health Education in Boston Teachers College and arranged a meeting for her class at the Boston Dispensary at which there was a demonstration by the Director of Health Education of methods of teaching nutrition to children. As a result three students in the class have come to the Dispensary on Saturday mornings throughout the winter and spring to join in the weekly health education conferences and to take a responsible part in teaching the children about food and health as they wait for treatment.

NEEDS OF WARD 9

The Committee on Needs of Ward 9 was formed originally because this district showed the highest incidence of tuberculosis.

At present the Boston Tuberculosis Association is doing intensive work there and, while the chairman of this Committee is actively concerned in it, it has seemed more important to the Committee to extend its work into other fields of health education.

Last year the exhibit of food values was carried out at the Whittier Street Health Unit and this year the Committee voted to undertake some educational work in social hygiene.

Our program was to get in touch with groups already formed in social or church organizations and arrange to send speakers to them. We are indebted to the State Department of Public Health for one speaker and to the Massachusetts Society for Social Hygiene for our other speakers. We have had cordial co-operation from the women's organizations of the neighborhood through Dr McGillicuddy.

Many men's clubs are carried on by churches and, through Dr Epstein's approach to the ministers, we were able to arrange talks in their churches.

Mr George W Goodman, Executive Secretary of the Boston Urban League and a member of this Committee, has been very helpful in making many of these contacts. Several doctors gave us their strong endorsement. Talks have been given by Dr McGillicuddy at the League of Women for Community Service, by Miss Craine at the Women's Service Club and also at a joint meeting of the Health Guild of the Boston Tuberculosis Association with the Mother's Club of Robert Gould Shaw House.

We are indebted to Dr Rolf Lium for speaking to groups at three churches and one club: Dudley Street Baptist Church, St. Cyprian's, Charles Street Church, and the 8-20 Club of Young Men, meeting at the Women's Service Club House.

Your chairman has heard most encouraging reports of the reactions of these groups to the talks, and Dr Lium also feels that the members have shown an intelligent interest through the questions that have been asked. Several of these groups were of very young men.

It is due to the co-operation of the Massachusetts Society for Social Hygiene that we have been able to carry out the plans made by this Committee.

NURSING

The Public Health Nursing Committee of the Boston Health League has held one meeting during the winter. It is felt that with the formation of the Hospital Council and the interest of the National Organization for Public Health Nursing in developing adequate nursing care to meet all the needs of a community that there should be a more inclusive organization than the Public Health Nursing Committee of the Health League. A subcommittee was therefore appointed to consider the advisability of forming a nursing council which would consider

nursing and nurses in relation to the community program. Meetings of this subcommittee have been held and it is planned to have a meeting of the larger group in the fall, when it is hoped definite recommendations regarding the formation of a nursing council will be presented.

PNEUMONIA

Since November 7, 1935, the Pneumonia Committee has sent a card to 1,774 practicing physicians, members of the Norfolk District Medical Society, the Suffolk District Medical Society and the Middlesex South District Medical Society, calling attention to laboratory facilities for the typing of sputum. The State Health Department reported that during December there was an increase in the use of the State laboratory facilities for this purpose by physicians in this area who had not formerly availed themselves of this opportunity.

In March 1936, reprints of the article written by this Committee which appeared in the January 30, 1936, issue of *The New England Journal of Medicine* were distributed to these physicians with a letter signed by the president and secretary of their respective medical societies, again calling their attention to the reduction of mortality for types I and II of lobar pneumonia if serum is used promptly. Dr Smillie requested copies for one of his classes at the Harvard Medical School and this article was also distributed to members of the Health League and was enclosed with 900 copies of the Bulletin of the Boston Council of Social Agencies.

The Committee is concerned with the question as to the best policy for lay education regarding the use of pneumonia serum, but has been of the opinion that physicians should first know the value of this therapy and how to obtain it, and has, therefore, not attempted lay education.

SOCIAL HYGIENE

There are three matters with which the Social Hygiene Committee has been particularly concerned. These are the following: (1) The co-operation with the Committee on the Needs of Ward 9 in stimulating interest in regard to syphilis and gonorrhea, on which Mrs Lord has reported. (2) The continuation of sponsoring the meetings of the Staff Council on Syphilis and Gonorrhea. Since November four meetings have been held with the following guest speakers discussing community problems:

Dr Nels A Nelson of the Department of Public Health who conducted a round table discussion on improved methods of a social service and administrative program for syphilis and gonorrhea. *Mrs Evangeline Morris*, Social Hygiene Supervisor of the Community Health Association, whose subject was "The Community Health Association and Hospital Clinics—Their Interrelationship."

Dr Harry O Solomon, who spoke on "New Treatment Methods in Neurosyphilis" with a demonstration of apparatus, and

Miss Ora M Lewis of the Massachusetts General Hospital who spoke on "The Public Health Department and Social Service"

The third matter is the study of social hygiene literature available in the Boston Public Library system. Several of the branches of the Boston Public Library have already been visited in addition to the main building with a view to ascertaining the situation in regard to the supply and demand for this literature. Branches in the remaining sections of the city will be visited so that some comparison may be made as to the uses which are being made of the available facilities and the Committee may know in which districts greater effort should be made to further educational activities in social hygiene.

REPORT OF DR. SILATTUCK

You have heard from chairmen of many of the committees about what has been done during the past year. I should like to say that the work has been steadily extended for a number of years with more and more being accomplished. Perhaps we do not realize that the permanent staff of the Health League is exceedingly small being the half time of the executive secretary and her assistant who work also for the Hospital Council and the full time of one stenographer. The Health League shares the telephone service with the Council of Social Agencies. It is obvious that a large part of the work must be done and has been done by volunteers many of whom are exceedingly busy yet willing to give of their time. Most of the committees whose reports you have heard today are continuing but temporary committees have been formed this past year and dissolved when their special task has been accomplished. We have had splendid co-operation. Membership on committees is not limited to board members or members of the Executive Committee. Whenever we see anyone who can help we ask that individual to serve and help us when and as he can. I should like also, to call your attention to this co-operation from *The New England Journal of Medicine*. Dr. Bowers has been interested in our work for years and has been most generous in publishing some of the things we wished to bring to public attention.

For the future we should continue to push the programs and policies for which we stand. We should bring more effectively to the attention of boards of member agencies, policies in which we need the help of their organizations. I wish to thank the board members who are here today and ask them to take up this matter with their organizations and give us greater co-operation along these lines and offer advice as to how we can be more helpful.

One of the major concerns of the Health League should be legislation. During the past, representatives of the organization have appeared at hearings in favor of many bills or to combat legislation which would be harmful to public health. Upon the completion of the report of the Massachusetts State

Health Commission the Boston Health League should concern itself with the recommendations which will be made to the next general session of the Legislature.

There being no further business the meeting then adjourned.

MARGARET H. TRACY, Secretary

CHAIRMEN OF COMMITTEES

Anna C. Palmer, M.D., Chairman Educational Committee on Cancer

Warren R. Slason, M.D., Chairman Child Health Committee

Mary Pfaffmann, Chairman Health Education Committee

Mrs. Frederick T. Lord, Chairman, Committee on Needs of Ward 9

Sophie C. Nelson, Chairman, Public Health Nursing Committee

Frederick T. Lord, M.D., Chairman Pneumonia Committee

Mrs. Maida H. Solomon, Chairman Social Hygiene Committee.

HAMPDEN DISTRICT MEDICAL SOCIETY

The Annual Meeting of the Hampden District Medical Society was held at the Skinner Memorial Clinic of the Holyoke Hospital Tuesday April 28, 1936 at 4 P.M. The President, Dr. Theodore S. Bacon was in the chair. About seventy members attended.

Dr. Hervey L. Smith, Secretary-Treasurer read the minutes of the previous meeting which were approved and submitted the Treasurer's Report showing a balance of \$536.07 after disbursements. He also noted that the dividend returned by the Massachusetts Medical Society this year for early payment of dues was the largest in the history of the District Medical Society also that the appropriation from the Hampden District Medical Society toward the expense of radio talks by Dr. Miles of Brockton, Chairman of the Committee on Education of the General Court, exceeded that of all the other district societies in the state.

According to the Secretary the average attendance per meeting was 100 the total active membership 301.

The President, Dr. Bacon reported that during the recent flood period, under conditions of interrupted communication, a Hampden District representative had attended a number of consecutive meetings of the Presidents of the District Medical Societies in order to discuss an important matter of ethics and discipline.

Nominations for officers of the Society for the ensuing year were made and seconded and the following were elected by the Secretary casting a single ballot:

President Dr. Patrick E. Gear of Holyoke.

Vice-President Dr. Allen G. Rice, Springfield.

Secretary-Treasurer Dr. Hervey L. Smith, Springfield.

A vote of thanks was given to the officers for the

the trichinella spiralis in their earliest stage are about ten times as long and twice as broad as a large organism such as the anthrax bacillus. In trichinosis just as in bacterial infection the lesions produced are essentially a combination of toxic manifestations plus embolic depositions. The recent researches of Bachman have definitely shown that from the very beginning of the disease evidences of toxemia are present, and this is shown by the very early appearance of a positive skin test which may occur even on the second day after infestation. Whether the toxemia is entirely due to products of the trichinellae or whether, as some suppose, it is partly due to toxins produced by the destruction of muscular tissue, is still an open question but as I shall point out later in discussing the symptomatology there is no lack of evidence of toxemia. There is also no lack of evidence that in addition to their toxic effect the parasites produce definite embolic effects which are comparable with those which are produced by bacteria in certain types of septicemia.

The second point that I wish to make is that the spectacular character of the lesions in the voluntary muscles which has dominated our conception of the disease since its first careful study by Zenker and Leukhart has led to the minimizing of important lesions in the internal organs, particularly the heart muscle and the nervous system, which are worthy of serious consideration inasmuch as they have a definite bearing on the symptomatology of the disease. I do not mean to infer that these lesions have been entirely overlooked, for the cardiac manifestations were described in 1918 by Simmonds¹ under the heading of myocarditis trichinosa, and were also carefully described and adequately illustrated by Channing Frothingham² in 1906. In essence, the pathological changes show that the embryo may be demonstrated in organs in which it does not encyst, and that in association with these parasites there are to be found localized destruction of tissue and cellular infiltration of a character extensive enough to produce damage in various internal organs which may result in demonstrable clinical manifestations.

SYMPTOMATOLOGY OF THE ORDINARY FORM OF TRICHINOSIS

One purpose of this article is to call attention to the fact that in addition to the ordinary form of trichinosis there exist unusual forms, to which attention has not been adequately directed. I think, however, that it will be well to describe first of all the common type of the disease.

The onset of the disease is not the same in all individuals. There is one group of patients in whom within a few hours after the ingestion of the infected meat, gastrointestinal symptoms

appear. These patients usually have nausea and vomiting, sometimes accompanied by abdominal cramps and diarrhea, and these symptoms may continue up to the time when the manifestations of the invasion of the body by the young parasites make their appearance. There is another group of patients in whom no immediate effect follows the ingestion of the infected meat. In these individuals there is an interval of time, at least six days and sometimes as long as four or five days, during which the patient is free from symptoms. When symptoms do occur they are those which are associated with the dissemination of the larvae through the blood stream. It is difficult to say why in one group of patients the gastrointestinal symptoms are prominent from the beginning and in the other group they are absent. It was formerly assumed that those patients who developed gastrointestinal symptoms within a few hours after the ingestion of the infected pork did so because the pork was not only infected with trichinellae but was also more or less putrified. The work of Bachman³ on the skin test indicates that toxins are present in association with the trichinellae from the very beginning of the infection and that there is therefore no need to assume that putrefactive changes were present. It is possible that the reason why some individuals do not develop gastro-enteritis at the beginning is a matter of dosage, that is to say, individuals who receive a heavy dose of infected material develop gastro-enteritis while those who receive a lighter dose do not develop symptoms until the trichinellae are invading the system. No doubt, too, individual resistance plays a part. The important point to remember is that, so far as onset is concerned, there are these two groups of cases.

The ordinary case of trichinosis develops symptoms associated with invasion of the blood and organs by the parasite about the end of the first week after infestation. As has been stated already, these symptoms are partly toxic and are partly due to the mechanical effects of the parasite. The fever, which is a prominent feature in well-marked cases, and the accompanying headache, general muscular pains and anorexia, are all doubtless of toxic origin. The swelling of the eyelids which is such a common finding in the disease, the chemosis, the occurrence of small hemorrhages beneath the conjunctivae and the occasional occurrence of skin lesions which simulate rose spots, are all embolic in nature. The symptoms which are associated with the invasion of voluntary muscles, such as muscular pains occurring later than those due to the toxemia and associated with muscular stiffness and tenderness and, particularly in children, with pseudo-paralysis, are also due to the lodgment and wandering of the parasites in the voluntary muscles. In the ordinary case the evidence of damage to the internal organs is usually not

very pronounced, with the exception of the pulmonary lesions which are quite common and present clinically in the form of a bronchitis, which is often accompanied by definite signs of bronchopneumonia. Many cases, however, do show a certain amount of evidence of myocardial weakness, and some of them show definite evidence of involvement of the meninges in the form of stiff neck, meningismus and sometimes extreme restlessness or delirium.

The ordinary case then presents the picture of a febrile disease, the fever varying in degree according to the intensity of the infection and lasting from a few days to six or seven weeks. The usual toxic accompaniments of an infection are present and in addition chemosis, edema of the eyelids, painful and tender muscles, subconjunctival hemorrhages and quite frequently pulmonary complications and cardiac weakness. Physical examination in the ordinary case shows changes which are very variable in intensity depending on the severity of the case. In any outbreak involving a number of individuals, and in this country we see mostly sporadic cases and family outbreaks, there are some who are obviously acutely ill and some who may hardly appear ill at all and may never have to go to bed. As a matter of fact in the infected families that I have seen there have usually been some members going about their business entirely unconscious of the fact that they were suffering from the disease. In such individuals fever and obvious muscular involvement do not exist, and a diagnosis of the disease would not be considered if the observer did not make a blood examination. The blood count and differential count are the most significant laboratory findings, and a leukocytosis with eosinophilia is only rarely absent. However it has not been sufficiently emphasized that in the early stages of the disease eosinophilia may be absent and that repeated blood examinations are often necessary.

THE UNUSUAL CLINICAL FORMS OF TRICHINOSIS

In addition to the ordinary type I wish to discuss briefly three forms of the disease which are of rather unusual occurrence and which have been generally recognized only since it has been appreciated that the lesions in the internal organs are at times just as important as the lesions in the voluntary muscles. There are three groups of these unusual cases: (1) those in which myocardial symptoms are prominent, (2) those in which the lesions in the central nervous system dominate the picture, and much more rarely, (3) those in which evidence of kidney damage is a feature.

The observation of Simmonds,⁴ who described a trichinous myocarditis in 1918, was followed by a long period when little or no reference was made to the clinical effect of trichinosis on the heart

was found in the literature. Recently interest in the subject has been revived by the articles of Weller and Shaw,⁵ Dunlap and Weller,⁶ and Spink⁷ who have once more called attention to the myocardial changes and the importance of their bearing on the clinical manifestations of the disease.

I can best illustrate the cardiac effects of trichinosis by briefly reporting a case seen with Dr. Gissler of Middletown in 1934 which showed both cardiac and renal symptoms.

An American schoolteacher aged twenty-seven on or about December 23, 1933 ate some fresh sausage meat which was insufficiently cooked. There was no immediate effect but about a week or so later the patient began to complain of pain in both knees but did not feel ill enough to call in a physician until January 20, 1934. At that time she was complaining of headache over both eyes, pain in the back of the neck, pains in the joints and diminished excretion of urine. The knees were slightly swollen and tender, there was tenderness over both eyes, the nasal mucosa was congested and the patient had a fever of a little over 100°. It was first thought that she had an acute upper respiratory infection with sinusitis, arthritis and possibly a mild nephritis. Several days later she consulted her physician again showing marked edema of the eyelids. The fever was about the same, the urine was still very scanty and there was definite puffiness of the eyelids with in addition some edema of the ankles. The presence of palpebral edema led to a blood count which showed 8500 leukocytes of which 26 per cent were eosinophils. She had no muscular tenderness but a biopsy was performed on one of her muscles and three trichinae were found in a teased specimen. At this time she was somewhat emaciated and still showed a pronounced diminution in urinary secretion. With an intake of 2500 cc. there was an average output of only 175 to 250 cc. on some days although occasionally as much as 1400 cc. were excreted. The bowels were very constipated. She continued to run fever and during the course of the disease a rash simulating rose spots appeared which was later followed by a marked urticarial rash. The leukocytes reached a maximum of 14,000 per cubic millimeter always accompanied by a pronounced increase in the eosinophils which rose as high as 34 per cent. Fever was seldom above 101½°. There was a trace of sugar in the urine at times but the blood sugar was only 80 milligrams per cent and the non-protein nitrogen was normal. There was no rise in the blood pressure. About March 4 that is to say after she had been sick for about two months she began to develop attacks of syncope with a sensation of coldness, a feeble pulse and rather scratchy heart sounds which were somewhat muffled and occasionally suggested the possibility of pericardial friction though no definite friction was detected. There were a good many rales at the bases of the lungs. There were attacks of palpitation with a regular rhythm and spells of weakness, which on one occasion were accompanied by air hunger, precordial pain and actual syncope. An electrocardiogram showed slurring of the peak of the QRS complex with other slight changes which suggested to the cardiologist a diagnosis of myocardial damage with left axis deviation. An x-ray of the heart was normal. Physical examination showed that the patient was propped up in bed and decidedly pale but did not appear very acutely ill when I saw her on March 18. There was still some pain on movement of the eyes, the calf muscles, deltoid and bi

ceps were still tender. There were a few moist râles at the bases of the lungs. The pulse was regular, of medium volume and moderately compressible. The heart sounds were clear and of fairly good quality. There was no enlargement of the liver, and no definite edema of the lower extremities. Under continued rest in bed the patient did fairly well but a report from Dr Gissler early in June, 1935 showed that she still had dyspnea on exertion, that her pulse was still 90 while at rest, and that at times she was orthopneic.

There can be little doubt, I think that this patient suffered severe cardiac damage as a result of her trichinosis. No doubt if an examination of the heart muscle had been possible we should have found degenerative changes in the myocardium such as were described by the authors named above, together with areas of cellular infiltration. The subsequent course of events indicates that the damage to the heart is probably more or less permanent. There is evidence, too, that in all probability there was some kidney damage, although it is possible that the marked diminution of urinary secretion was partly due to the cardiac insufficiency. However, it would certainly be unusual for cardiac insufficiency alone to produce such a marked diminution of urinary secretion as occurred at times in this case, especially since the blood pressure was never very low. It is true that the urine never showed more than a trace of albumin with an occasional red blood cell and an occasional leukocyte, and that casts were never present.

The *second group* of cases to which I wish to call particular attention are those in which there is marked evidence of damage to the central nervous system. There are a fair number of cases of the ordinary type in which stiffness of the neck and a Kernig's sign are present but I am referring to patients who show evidence of involvement of the parenchyma of the nervous system or of the nerves.

Aside from the cases showing evidence of meningism there are two groups of cases which show more pronounced evidences of gross damage to the central nervous system: (1) patients with hemiplegia, and (2) patients with symptoms which must be interpreted as encephalitis.

The following patient illustrates well the first of these two groups.

An American truck driver, aged twenty-six, was seen with Dr Brophy, of Norwich, on December 7, 1935, at which time the patient was completely unconscious. In the course of his work he made extended trips, frequently ate at all sorts of places and was known to have occasionally eaten pork.

His illness began rather acutely on November 22, 1935. At this time he complained of being drowsy, suffered from nausea and vomiting, was running a fever ranging from 100° to 101°, and had swelling of the face with edema of the eyelids. When first seen by Dr Brophy on November 25 there was definite injection of the conjunctivae, a coated tongue, swollen eyelids, rigidity of the neck, and a good

deal of complaint of lumbar backache. He was passing large quantities of amber colored urine and was sweating profusely. He continued to run a temperature of from 99½ to 100, and on December 3 became mentally confused, fell out of bed, complained of numbness of the left arm and leg, and subsequently became delirious. At this time examination of the blood showed a leukocyte count of 20,000, with 44 per cent eosinophils. He was sent to the hospital where, after twenty-four hours, he became comatose and his left arm became spastic. The next morning the arm became limp and this condition still persisted at the time I saw him on December 7. The urine contained only a slight trace of albumin and no casts. A lumbar puncture showed no increase in cells but a definite increase in globulin and sugar.

When I saw him on December 7, 1935, he was completely unconscious and could not be aroused. There was a constant, slow, side-to-side movement of both eyes. The pupils were equal in size, moderately wide, but reacted poorly to light. It was rather difficult to see the eyegrounds on account of the movement of the eyes but so far as could be judged they were normal. There was no retraction of the head or stiffness of the neck. The left arm and leg were flaccid, with a slight increase in the deep reflexes. There was a suggestion of ankle clonus on both sides but there was no definite Babinski. The superficial reflexes were very sluggish. The lungs were clear. The heart was not enlarged and the heart sounds were clear. Blood pressure 114/72, and the pulse was regular, of medium volume, and compressible. No changes could be detected in the abdominal organs. Another specimen of spinal fluid was obtained and was sent to the Laboratory of the State Department of Health where trichinal larvae were recovered. About December 18 the patient regained consciousness. By December 26 power began to return in the arm, though the leg was still completely paralyzed. By December 29 there was some movement of the toes and on January 8 the patient sat up, completely recovered so far as his mental status was concerned, but with a residual partial paralysis of the left arm and leg.

I have had no personal experience with cases of trichinosis presenting the picture of encephalitis but such cases have been reported by Pund and Mosteller,⁸ and by Gordon, Cares and Kaufman.⁹

In Pund and Mosteller's patient, a colored boy of eleven years, there was drowsiness, hypertonicity of the muscles, and diminished reflexes three weeks after vaccination against smallpox. The patient showed a leukocytosis of from 12 to 16 thousand but there was no eosinophilia. He died and an autopsy showed inflammatory foci in the cortex, in the basal ganglia, the medulla, and the cerebellum. These foci contained trichinellae. There was also a myocarditis.

In addition to these two types of involvement of the nervous system, there are other rarer types which may simulate poliomyelitis and polyn neuritis. These have been well described by Merritt and Rosenbaum¹⁰ who give a very thorough review of the literature.

These cases of neurological involvement in trichinosis are not very common but now that they are known it will probably be found that they are less uncommon than was formerly

thought. They illustrate the axiom that "cerebral localization indicates the situation of a lesion but not its nature," and they call attention to the fact that in obscure febrile neurological lesions of the brain and cord and even of the peripheral nerves trichinosis must be considered as a possible etiological factor.

THE DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS OF TRICHINOSIS

In one of his articles Bachman states that the diagnosis of trichinosis is difficult. This is doubtless true of the unusual types as is likely to be the case in most diseases. The diagnosis of the average case of trichinosis is not difficult if the practitioner is aware of the common clinical picture. Any febrile disease which is accompanied by edema of the eyelids and evidences of involvement of the muscles at once calls for a blood count. In most cases of trichinosis eosinophilia will be present. In the unusual case where it is not present repeated blood counts are called for as it may develop later in the disease. I have called particular attention to the edema of the eyelids because this is almost always present and is not a feature of other general infections with which trichinosis is likely to be confounded.

If after the use of the ordinary tests there is still doubt as to the diagnosis the skin test of Bachman may be of value. The reaction occurs in a large percentage of cases of trichinosis, it is present early in the disease and it is clear out in positive cases.^{11, 12} Bachman's precipitin test is of much less value because it does not appear for three weeks or more after the onset of the disease.

Needless to say the finding of the embryo parasite either in a piece of excised muscle in the feces in the blood or in the spinal fluid clinches the diagnosis. However, no one of these methods is 100 per cent perfect. Unless an infected muscle is chosen the pathologist may draw a blank. The finding of parasites in the blood, the feces or the spinal fluid occurs only in a relatively small proportion of infected patients.

With regard to the differential diagnosis the following conditions are important:

The disease which is most commonly mistaken for trichinosis is typhoid fever. In an epidemic of typhoid fever which occurred in Boston some years ago investigation by the Board of Health demonstrated that twenty cases that had been diagnosed typhoid fever were in reality trichinosis. The mistake is not likely to be made if it is borne in mind that edema of the eyelids is not a feature of typhoid fever and that the blood picture in the two diseases is entirely different. There is of course no positive Widal reaction in trichinosis and there is almost always

a well marked leucocytosis with eosinophilia. However, there are certain points common to the two diseases so that there is a superficial resemblance. The fever in trichinosis is usually of the remittent type and quite comparable with the fever of typhoid. Bronchitis is frequent in trichinosis and occasionally a papular rose-colored eruption is present in this disease.

On account of the prominence of the eye symptoms some patients with trichinosis fall into the hands of the ophthalmologist before consulting the internist. The eye muscles are often extensively invaded by the trichinella and consequently pain on movement of the eyes is a not infrequent symptom. This may be so intense as to lead to the patient fixing the gaze. Furthermore, chemosis of the ocular conjunctiva is a frequent symptom and these symptoms, together with the edema of the eyelids, suggest to the patient that the trouble is with the eyes. An alert ophthalmologist will usually have a blood count which will at once lead to the suspicion that the process is a local manifestation of a general disease rather than a primary eye disease.

As Pratt pointed out many years ago, some of these patients first consult a nose and throat specialist. Severe headache and edema of the face, particularly in the region of the eyelids may lead to the suspicion that the patient is suffering from sinusitis. Here again the almost negative findings in the nasal cavities and paranasal sinuses will lead the alert nose and throat man to the suspicion of a general disease, and a blood count will put him on the proper track.

There is one disease which simulates trichinosis fairly closely, and that is the so-called acute dermatomyositis which has sometimes been called pseudotrachinosis. This disease is very rare however. It is often preceded by an acute upper air passage infection. It is generally accompanied by an erythematous eruption on the face without edema of the eyelids and the muscles which are usually involved are those of the extremities, where the overlying edema which accompanies the myositis is located. Furthermore, dermatomyositis is not accompanied by eosinophilia.

There are some cases of trichinosis in which the meningeal symptoms are so pronounced that a suspicion of meningitis may be aroused. As a matter of fact there is actually a trichinous irritation of the meninges in a fair number of cases of trichinosis and this may be accompanied by an increase in the cells and globulin. As Van Cott and Linz first pointed out the embryos may be found in the spinal fluid in these cases. The course of the disease, together with the blood findings, clears up the diagnosis.

On account of the edema of the face a diagnosis of Bright's disease is not infrequently

made in patients with trichinosis. However, most patients with acute Bright's disease are free from fever, the urinary changes in trichinosis are usually merely those of febrile albuminuria and the leukocytosis and eosinophilia differentiate the two conditions.

The cases in which involvement of the myocardium is a prominent feature can usually be recognized without difficulty because the myocarditis is merely an incident in the disease rather than the predominant feature. These patients, as illustrated by the case reported, show other evidences of trichinosis and there is generally no difficulty in recognizing them.

The same cannot be said of the cases in which involvement of the nervous system is a prominent feature. In these patients the clinical evidences of nervous disease, such as hemiplegia or symptoms suggesting encephalitis, are so outstanding that the clinician may at first be led astray. However, there are usually other evidences of trichinosis if the disease is thought of. Edema of the eyelids, muscular tenderness, and the characteristic blood changes should permit the clinician to avoid error.

THE TREATMENT OF TRICHINOSIS

It is obvious that patients with trichinosis must be treated along the lines that have been established for the treatment of any general febrile disease. The patient must be kept in bed, an adequate supply of fluids and nourishment must be furnished, a preliminary purge should be given because some parasites may persist in the intestines for a considerable period, pain must be relieved, and the patient must be assured of a proper amount of sleep.

There have been many attempts to treat the disease by destroying the parasites in the body. A great variety of different drugs has been employed for this purpose, notably arsphenamine, but also thymol and other antiseptics. The experimental work of Miller, McCoy and Bradford¹³ with neoarsphenamine, antimony and potassium tartrate, acriflavine, rivanol, gentian violet, metaphen, and Lugol's solution showed that all of these drugs were useless. The results which have been obtained in human beings are contradictory and, when the natural history of the disease is considered, it would seem that so far no definite results have been achieved. There is some question, I think, whether it is desirable to destroy, at one fell swoop, the enormous numbers of parasites which are present in the body. It would be possible, if an effective parasiticide were discovered, that the destruction of the parasites *en masse* might result in a sudden flooding of the system with large quantities of toxic substances. It is obvious that the parasites cannot be removed from the body after they have left the intestinal tract

and it is well known that ultimately those which survive become encapsulated and comparatively harmless.

The quest for an effective antitoxic serum of fers, I think, a more hopeful solution. McCoy's¹⁴ work on rats shows that a natural immunity can occur after light infections, and while the work of Schwartz¹⁵ shows that immune serum does not damage the parasites and this has been confirmed by Hall and Wigdor,¹⁶ this does not prove that a serum might not neutralize the toxemia. The results of Salzer¹⁷ who used serum from recovered patients are decidedly encouraging and warrant a further trial of this method.

Whether the use of calcium as advocated by Goldschlager,¹⁸ or the administration of vitamin D to accelerate calcification as proposed by Barker and Wantland¹⁹ will prove of value needs further investigation. Under normal circumstances calcification of the encysted trichinellae does not begin for at least six months after infestation, and the degree of acceleration of the process in man has not yet been demonstrated.

MEDICOLEGAL ASPECTS OF TRICHINOSIS

In conclusion I wish to say a few words about the medicolegal aspects of trichinosis, because during this period of depression an unusually large number of lawsuits have been brought against both wholesale meat dealers and retailers of pork. The assumption underlying these suits is that the wholesaler or the retailer is responsible for the illness of the patient because he has offered for sale food unfit for consumption. I would point out that the United States Government and also the German government long ago gave up attempts to eliminate trichinosis by microscopic examination of pork. The late Charles Wardell Stiles pointed out many years ago that the microscopic examination of pork was a futile procedure. He showed that of 6,329 cases with 318 deaths which occurred in Germany, 2,402 cases and 112 deaths followed the consumption of government inspected meat released to the trade as free from trichinae. It is perfectly obvious from these figures that the government inspection of pork entirely fails to eliminate infected meat. It follows from this that suits against meat dealers are, at least from the medical point of view, a racket pure and simple. The only effective prevention of trichinosis lies in the adequate cooking of pork and the individuals responsible for the occurrence of the disease are not the meat dealers, but the meat consumers.

THE SYNDROME OF ALKALOSIS COMPLICATING THE TREATMENT OF PEPTIC ULCER*

Report of Cases With a Review of the Pathogenesis, Clinical Aspects and Treatment

BY HAROLD JEGHERS, M.D.,† AND HENRY H. LERNER, M.D.†

MUCH has been written about the complications of peptic ulcers such as hemorrhage, perforation, obstruction, or malignant changes. There is still another complication arising during the usual Sippy treatment of a peptic ulcer with alkaline powders, which, if unrecognized, can have as serious a consequence as any of the above-mentioned sequelae. This little understood complication was first described in 1923 by Hardt and Rivers,¹ who gave to it the name of alkalosis. Since it has been the subject of but few reports and is not described in some textbooks, the clinical picture is probably an unfamiliar one to many physicians. Because many of the data available are in the form of statistics, it was felt that the report of three additional cases along with a brief review of the clinical syndrome, and the basic physiological factors probably responsible for it, would be desirable.

Cooke,² in reviewing the literature in 1932, found only sixty-eight reported cases (including nine of his own), with a mortality of 44 per cent. Since then forty-three additional cases have been described by Rafsky et al.,³ Jordan and Kiefer,⁴ Berger and Binger,⁵ Gatewood et al.,⁶ Oakley⁷ and others.

INCIDENCE

These few reports would seem to indicate a very low incidence of this complication, considering the frequency of peptic ulcer. However, it is interesting to note that while the total number of cases is small, each investigator reporting noted in his own series of peptic ulcers, an incidence varying from 2 per cent by Rafsky,³ 4.5 per cent by Cooke² to 18 per cent by Gatewood.⁶ Gatewood⁶ states that Sippy in his early clinics found that 17 per cent of his cases had a plasma carbon dioxide combining power of over 80 volumes per cent. A few authors (MacLean⁸ and Bloch and Serby⁹) state that they have rarely seen any such complications in their series of peptic ulcer cases.

This variation in incidence is probably best explained on the basis of different dosages plus the fact that recognition of the mild cases requires not only the knowledge of the clinical

features but adequate laboratory studies of all peptic ulcer cases under alkaline therapy. Jordan and Kiefer,⁴ in an excellent study of five hundred and seventy-seven cases of peptic ulcer, reported an incidence of 8 per cent (transient alkalosis 2 per cent, mild alkalosis 3 per cent, and severe alkalosis 3 per cent). Considering the size of this series, these values probably approach the true incidence. A complication of peptic ulcer of such frequency certainly deserves more attention than it is receiving in the literature at present.

PATHOGENESIS

Originally Hardt and Rivers¹ regarded the nonmetallic ions present in the alkaline powders as the cause of the toxic symptoms. However, their added suggestion that the condition simulated the gastric tetany produced by McCallum in dogs with mechanical pyloric obstruction and a consequent loss of hydrochloric acid, a decrease in the chloride of the plasma, and an increase in the alkali reserve, proved to be closer to the truth as shown by later studies. It is now well recognized that in the severe cases, the clinical and laboratory picture of alkalosis resembles that seen in cases of persistent pyloric obstruction.¹⁰ That one or more of the following mechanisms may be responsible and that the clinical course of the case is determined by the degree and number of factors present is probably true.

(1) *Loss of Gastric Juice* Normally the gastric juice contains chlorides secreted by the gastric mucosa. Originally, these chlorides were held in the blood in combination with basic ions. Under the normal process of digestion, the chloride ions of the gastric juice are reabsorbed and recombined with the basic ions of the blood. Failure to reabsorb the chloride ions results in an excess of uncombined basic ions in the blood stream. These, not having chloride to unite with, combine with carbon dioxide already present in the blood to form bicarbonates. As a result, the carbon dioxide combining power of the blood increases and a state of alkalosis is present. Excessive vomiting, and, in rare instances, gastrocolic fistulae can result in the loss of enough chloride to cause hypochloremia. An added factor is that in peptic ulcer the gastric contents are those of hypersecretion and hyperchlorhydria. When vomiting ensues in such a case, chlorides and fluid are rapidly lost in relatively large amounts.

*From the Fifth (Boston University) Medical Service, Boston City Hospital, Evans Memorial and the Medical Service, Massachusetts Memorial Hospitals, and the Department of Medicine, Boston University School of Medicine, Boston, Mass.

†Jeghers, Harold—Resident in Medicine, Fifth Medical Service, Boston City Hospital. Lerner, Henry H.—Resident in Roentgenology, Massachusetts Memorial Hospitals. For records and addresses of authors see This Week's Issue, page 1253.

Vomiting is by no means a constant concomitant of alkalosis however, as is shown by the reported instances where it was not present or only developed after the syndrome was manifest.^{2,7} It is interesting to note that vomiting associated with carcinoma of the stomach rarely causes hypochloremia because of the associated and preceding achlorhydria.

(2) *Pre-existing Renal Disease* The importance of the kidneys in maintaining a constant pH value of the blood is well established. To compensate for an increase in blood alkalies, the normal kidneys will excrete large amounts of basic ions (diuresis of alkaline urine) until the osmotic requirements of the blood are disturbed. When this occurs there is a diminution in the urinary output, while the blood carbon dioxide and nitrogenous constituents increase. It is uncertain whether this is due entirely (1) to the nitrogenous degeneration caused by toxic products or (2) to failure on the part of the kidney to secrete those products, or (3) to an attempt on the part of the kidneys to maintain the osmotic pressure of the plasma.

Pre-existing renal disease was long under suspicion as a factor in causing this secondary retention and bringing about the development of alkalosis. Wilkinson and Jordan¹¹ seem to have shown definitely that preceding renal pathology does exist in those cases of peptic ulcer which develop alkalosis while under alkaline therapy. By the use of the sulphate clearance test before alkaline therapy was begun they were able to show that kidney damage pre-existed in those patients who later developed symptoms of alkalosis, and did not exist in a control group of patients who responded well to the same treatment. Jordan and Kiefer⁴ in addition noted a definite clinical correlation between alkalosis and hypertension, arteriosclerosis and vascular nephritis.

While conceivable, there is no evidence at present that alkalosis cannot develop in patients with normal kidney function. In such cases, Rafsky² felt that these patients were sensitive to alkalies. It has however been shown by Wilkinson and Jordan¹¹ that these individuals are invariably those with unpaired renal function.

Since the syndrome of high intestinal obstruction with vomiting is known to occur in the absence of kidney damage,¹⁰ it is conceivable that the syndrome of alkalosis (which it resembles closely) complicating peptic ulcer without pyloric obstruction may occur in the presence of normal kidney function provided enough additional factors besides the dosage of alkali are present.

(3) *Hyperalkalinization* In the normal person the ingestion of large doses of alkali is followed by a compensatory alkaline diuresis which

prevents the development of alkalosis. No satisfactory evidence has been adduced that prolonged increased alkali intake, per se can cause kidney damage in human beings. Experimentally, Addis et al¹² were unable to produce hematuria and hydronephrosis in a large percentage of rats fed on a long-continued alkaline diet, and microscopic study showed no abnormality in the kidney parenchyma, although the rats on an alkaline diet had higher blood ureas than a control group. Nuzum et al¹³ feel that an alkaline diet is capable of causing moderate hypertension and renal damage in rabbits. Stieglitz¹⁴ states that it may cause renal irritation and on occasion true nephrosis. Gatewood et al⁶ do not believe renal injury can result from the intake of alkali. It is probable that this factor is more dependent on the previous state of kidney function than on the amount of alkali ingested or its possible effect on a normal kidney.

Although it is generally accepted that the systemic effect of alkalies is due to the soluble carbonates and citrates, the action of the insoluble salts in fixing the gastric secretion and thus preventing the neutralization of the alkaline pancreatic juice permits the reabsorption of the latter into the blood from the small intestine thus tending to increase the blood alkali.

(4) *Insufficient chloride intake* Froun¹⁵ in experimenting with dogs deprived of salt in their diet, was able to produce symptoms similar to those seen in alkalosis. It is well known that patients on a Sippy diet have a daily salt intake of about two grams instead of the normal ten to fifteen grams. In this respect Eusterman¹⁶ states that he feels that the use of the salt free diet in cases of hypersecretion is useless. He permits his patients enough salt to make the food palatable. By itself, this factor is probably unable to cause a clinically significant hypochloremia, but must be considered as contributory.

(5) *Hemorrhage* Boekus and Baak¹⁷ suggest that the chloride lost through hematemesis may be a factor in aggravating the alkalosis and delaying the response to therapy. This would seem to agree with the findings of Jordan and Kiefer,⁴ Imbille¹⁸ and Evans.¹⁹ It is doubtful whether hematemesis alone could ever be a primary cause but it probably should be considered as an important contributory factor.

In the large series studied by Jordan and Kiefer,⁴ the influence of gross hemorrhage on the success of therapy was shown to be of considerable importance. Out of forty seven unsuccessfully treated cases thirteen of which they attributed to hemorrhage three developed alkalosis. Undoubtedly the minor degrees of anemia present in other instances could be

normal may not occur until several weeks or more after the acute episode. Normal values for chloride excretion can be taken as one of the indications of the efficacy of treatment.

One of the most significant findings is the lowered values for the blood chlorides which may drop from 500 mg per cent to a level of 350 mg per cent. Enough sodium chloride should be given to keep the chlorides at a high level. Under adequate therapy it will return to normal in a few days. Periodic blood chloride determinations should be used as a means of checking the therapy.

The blood nonprotein nitrogen rises characteristically and often reaches values of 100 mg or more. Any value over 40 mg is considered indicative of retention. Similar rises are noted for other nitrogenous products such as urea, uric acid, and creatinine. Serum sulphates over 5.5 mg are considered abnormal. Under successful therapy the nonprotein nitrogen values return to normal slowly taking weeks or even months.

A valuable test in the diagnosis of alkalosis is the estimation of the alkali reserve (carbon dioxide combining power) of the blood which usually shows a marked rise especially in the more severe cases. Slight rises of 10 to 20 vol per cent are common. Tetanic symptoms are more apt to be manifest when the value reaches from 80 vol per cent to 100 vol per cent. Under proper therapy the carbon dioxide combining power returns to normal quite rapidly.

THERAPY

Treatment is simple and results in a prompt recession of symptoms and rapid improvement of the patient.

In the severe cases with vomiting and tetany, complete restriction of all foods and alkalies by mouth is the first therapeutic step. Hyper-tonic or physiologic saline solution is then given intravenously or per rectum.²⁵ At least 20 grams of sodium chloride should be given daily by parenteral routes and when possible by mouth. This serves to control the emesis and rapidly raises the blood chloride to normal levels. Chloride replacement, which is the basis of the therapy, must be continued until the blood chloride reaches normal and a balance is established between intake and output as determined by daily urinary chloride determinations and occasional blood chloride values. Four thousand cc of fluid containing glucose should be given daily. As soon as clinical improvement is noticed the patient is put on a high carbohydrate high salt low protein liquid diet which is gradually changed to solids. Clinical improvement may be noted before the laboratory studies show normal values.

Although the administration of water and sodium chloride usually relieves vomiting it has

been shown experimentally⁴ that this treatment is not always successful, because in the cases with vomiting there is a deficiency of chloride and hydrogen ions (especially when the alkaline pancreatic secretion is not being lost). It would seem logical, therefore that replacement with hydrochloric acid should be the correct treatment. Along these lines Webster and Armour²⁴ managed to obtain spectacular cures by injecting hydrochloric acid intravenously into dogs which had lost so much gastric juice and body fluids that they could no longer respond to the use of solutions of sodium chloride. Further study of this method may give it a place in the treatment of alkalosis. In severe cases where saline solution does not help and where a marked disturbance of kidney function exists the cautious use of acid might be attempted.

Calcium therapy is useless, for no change occurs in blood calcium to suggest it as a causative factor. When tetany occurs during this syndrome, it is usually promptly relieved by the chloride therapy.

In the milder cases where the symptoms are merely suggestive of alkalosis and the clinician is astute enough to realize the fact, simple withdrawal of alkalies alleviates the disturbance. Here the problem of how to treat the peptic ulcer patient who is refractive to alkalies or has recovered from the severe, acute manifestations of alkalosis arises. In the former instance, where continued treatment with alkaline powder is desired it may be possible to build up a so called alkali tolerance by graded doses. It would perhaps be wisest first to determine the status of kidney function in these cases and to use this fact as a basis for treatment. In some instances, trisodium phosphate may be substituted for the usual alkalies. In those cases where it is felt alkalies should not be used frequent feedings, mean therapy, histidine nonspecific protein therapy, alumina cream, constant milk drip without alkalies, colloidal aluminum, and sedatives are worthy of trial. Atropine for relief of spasm and its possible effect on secretion may be used. Some combination of these therapeutic procedures will probably be effective. If chronic vomiting (occasionally self-induced) is at fault and pyloric stenosis or spasm cannot be eliminated, then surgery is indicated.

In addition to specific therapy the case should be thoroughly studied and other factors eliminated. Anemia, if present, should be treated with iron or transfusions, if necessary. The presence of a renal lesion may require modification of a prescribed diet. In any ulcer case under alkaline therapy it may be advisable to make periodic examinations of the urine and if it is alkaline, it should not be permitted to exceed a pH of 7.

A practice to be cautioned against is the use

of alkalis in their usual form, that is, teaspoonful doses of a powder, because inaccurate measuring by the patient may lead to a great variation in dosage. For this reason Evans¹⁰ advised the use of alkalis in solution.

CASE 1 This thirty-one year old male truck driver was admitted to the Fifth Medical Service, Boston City Hospital, complaining of abdominal pain and vomiting. The patient was known to have had a duodenal ulcer for thirteen years. The diagnosis had been confirmed by x-ray examination on two occasions. Complete relief of ulcer symptoms had been obtained by means of diet and alkaline powders until eight months before admission. At first, belching developed, later to be followed by epigastric pain and distress. Therapy no longer helped

dirty and carious, and the gums showed definite pyorrhea. The eyegrounds were normal. Slight cervical adenopathy was noted. There was some tenderness from deep palpation in the epigastrium. The heart and lungs were normal. Blood pressure was 120 mm Hg systolic and 90 mm Hg diastolic. The muscles of the legs were slightly tender to touch. Reflexes were very lively but no tetany was noted. Temperature, pulse and respiration were normal.

Laboratory Data

On admission the urine showed a specific gravity of 1.011, a trace of albumin and a few casts. Twelve urine specimens between April 13 and June 19 showed specific gravities of 1.008 to 1.012, traces of albumin, hyaline casts and alkaline reactions. Hemoglobin varied from 54 to 77 per cent (Sahl).

CHART 1 Laboratory data from Case 1

him, although for months he lived on milk, crackers and alkalis. Relief was secured by induced vomiting, which procedure was resorted to daily. Two weeks before admission he had a slight hematemesis for the first time. Following this he began to notice dizziness, nervousness and irritability. Shooting pains and aches in his legs developed. For several weeks, he had nocturia once or twice

Family history, social history and past history were essentially irrelevant except for the following data. He had had measles, mumps, pertussis, diphtheria and scarlet fever. He denied any renal disease or any symptoms referable to his genitourinary tract. In 1929 he was in the Boston City Hospital for treatment of duodenal ulcer. At that time the blood pressure was 125/80. Examination of the urine revealed a specific gravity of 1.022, no albumin or casts. The nonprotein nitrogen of the blood was 33 mg/100 cc. Renal function tests were not done at that time.

Physical Examination

Physical examination revealed a well developed and well nourished man in slight distress. His apparent weight was about 155 lbs. The teeth were

and red blood count from 2,840,000 to 3,840,000. Smears of blood were normal as were the white blood counts. A Kahn test was negative.

Stools showed persistent positive benzidine tests for occult blood for a month, after which they became negative.

The nonprotein nitrogen of the blood at the time of admission was 130 mg per cent, plasma chlorides 430 mg per cent, urea nitrogen 83 mg per cent, creatinine 6 mg per cent, and carbon dioxide combining power 82 volumes per cent. Phenolsulphthalein test showed an output of 4 per cent for the first hour and of 8 per cent output for two hours. A Mosenthal test showed fixation of specific gravity of urine (1.007 to 1.010) with a great increase in the night volume over the day volume.

X-ray examinations of the gastro-intestinal tract showed a slight amount of residue in the stomach at the end of six hours and a tender irritable duodenal cap. The roentgenologist made a diagnosis of partially obstructing duodenal ulcer.

Course

All alkalis were discontinued. The intake of fluids was increased to 4000 cc per day. For the first week the patient received daily 30 grams of

sodium chloride intravenously in the form of 0.9 per cent saline solution. Later sodium chloride 15 grams three times a day was given by mouth. Frequent feedings of a first week Sippy diet were allowed.

Under this régime definite improvement was noted. His muscle pains and nervousness disappeared rapidly. After one week vomiting ceased. Nocturia persisted for two months.

Change in the various constituents of the blood and urine are plotted in chart 1.

An x-ray examination on June 18 showed no pyloric obstruction. Upon discharge June 2, the nonprotein nitrogen of the blood was 50 mg per cent, plasma chlorides 588 mg per cent, creatinine 19 mg per cent and carbon dioxide combining power 42 volumes per cent. Phenolsulphonphthalein output in two hours was .3 per cent. A flat plate of the abdomen revealed no kidney calcification. Blood pressure was 15 mm Hg systolic and 85 mm. Hg diastolic.

The patient was discharged on June 27 definitely improved. He was told to use the prescribed diet and atropine but no alkaline powders. He reported at intervals that he has continued to be free from symptoms. In September 1935 the nonprotein nitrogen was 45 mg per cent and the urine showed a specific gravity of 1.010 a trace of albumin and a normal sediment.

Comment

In reviewing this case it is difficult at first to evaluate the many factors which precipitated the alkalosis. There is no evidence either in his history or the previous hospital records that he had renal damage. It seems odd also that he could tolerate alkaline therapy for so many years without any complications developing if this were the major factor. Probably it was the combined action of anemia, salt deprivation, hematemesis, excess of alkali and persistent vomiting which finally precipitated the full syndrome of alkalosis and hypochloremia.

The clinical picture and laboratory data are typical of this complication. The normal blood pressure throughout and lack of cardiac failure eliminate hypotension or congestive changes in the kidney as the cause for renal failure. The rapid improvement on saline therapy alone indicates that upper intestinal obstruction was not the cause of his symptoms.

CASE 2. This forty-eight year old male apprentice entered the Fifth Medical Service Boston City Hospital on September 22 1935 complaining of abdominal pain.

Present Illness

Three years before admission he developed typical abdominal pains of duodenal ulcer and vomited blood. The diagnosis of ulcer was confirmed by x-ray examination. Relief was obtained by a Sippy régime and alkaline powders. After several months he was able to discontinue therapy and remained symptom free until July 1935. Pain and vomiting then returned. There was no bleeding.

From August 3 to August 17 1935 he was studied at the Boston City Hospital. A diagnosis of obstructing duodenal ulcer was made and relief again secured by a Sippy régime and alkaline powders. At that time the urine was alkaline with a specific gravity of 1.010 no albumin or casts. Red blood count and hemoglobin were normal. Stools were free of occult blood. Nonprotein nitrogen was 30 mg per cent blood pressure 15 mm Hg systolic and 80 mm Hg diastolic.

After several weeks the symptoms again recurred. Vomiting increased and soon followed each meal.

There was a loss of weight amounting to twenty nine pounds in three months. Melena or hematemesis did not occur.

Past History

This was irrelevant except that nocturia once or twice had been noted for the past four years. He denied genitourinary or kidney diseases.

Physical Examination

Blood pressure was 120 mm Hg systolic and 80 mm Hg diastolic, and the pulse 70 per minute. Physical examination was essentially normal for his age and showed no abnormalities except pyorrhea and slight epigastric tenderness from deep pressure. The eyeballs and prostate were normal. The blood vessels were not sclerotic and there was no evidence of past renal damage.

Laboratory Data

At the time of admission the urine was alkaline the specific gravity was 1.022 albumin and sugar were absent and the sediment was normal. Hemoglobin was 61 per cent the red blood cells numbered 3,450,000 per cu mm the white blood count and smear were normal. Kahn test was negative. Stools did not contain occult blood. Nonprotein nitrogen was .9 mg per cent.

Course

The patient was treated with a Sippy diet sedatives, atropine and alkaline powders. In spite of this his distress continued and he vomited almost daily. An x-ray examination on October 1 1935 revealed partial retention of the barium meal in the stomach at the end of six hours.

In addition to his abdominal pain and vomiting the patient began to complain of slight headache, tinnitus and cramps in his legs. The cramp-like pain in his legs became so severe by October 15 that alkalosis was suspected and confirmed by laboratory data. At this time the physical examination showed no change except pain on squeezing the calf muscles, very hyperactive reflexes and slight conjunctivitis of the lids. No tetany could be elicited.

On October 15 1935 his urine was alkaline specific gravity 1.010 with a trace of albumin but no casts. Nonprotein nitrogen of the blood was 110 mg per cent plasma chlorides 500 mg per cent and carbon dioxide combining power 60 volumes per cent. Stools were negative for occult blood. Red blood count and hemoglobin remained the same. Blood pressure was 15 mm Hg systolic and 55 mm Hg diastolic. Phenolsulphonphthalein excretion amounted to 10 per cent in two hours. Mucous test of the urine showed a fixed low specific gravity with a high night volume.

Alkalies were omitted and 30 grams sodium chloride and 3000 cc of fluids were given intravenously daily. There was rapid improvement of his symptoms vomiting ceasing within a few days. Detailed changes in his laboratory data are plotted on chart 2.

A pyelogram showed a shadow suggesting a calculus in the right kidney. Blood calcium was 8.9 mg per cent phosphorus 3.6 mg per cent phosphatase within normal limits.

On November 15 1935 the patient had recovered enough of his kidney function to withstand the performance of a posterior gastro-enterostomy. Convalescence was uneventful. At the time of discharge his blood pressure was 130 mm Hg systolic and 85 mm Hg diastolic. The urines were alkaline with a specific gravity of 1.014 no albumin and a normal sediment. Phenolsulphonphthalein test showed 40 per cent output in two hours. The nonprotein nitrogen of the blood was 31 mg per cent.

Comment

This patient presented what is better called hypochloremia rather than the complete alkalosis syndrome. If treatment had not been instituted early, the carbon dioxide combining power of the blood probably would have increased and more marked symptoms resulted. The history of longstanding nocturia and the possible presence of kidney stone point to kidney damage as one of the precipitating factors. In addition, persistent vomiting, low salt intake, and slight anemia probably all played a rôle. It is difficult to say why the syndrome should develop suddenly while under observation unless it was that he received more alkaline powders after admission than he had taken at home. Determination of blood chlorides on admission would undoubtedly have shown changes from normal. Because of the early diagnosis in this patient, a much more rapid improvement was noted than in the first case

when he began to have frequent attacks of nausea and vomiting. Thinking these were due to his ulcer, he took increasing amounts of alkaline powders, but failed to obtain the usual relief. He became quite irritable, and complained of severe occipital headaches. On July 8 vomiting persisted, and he complained of tingling sensations over his entire body. His muscles felt stiff and twitched spasmodically. He was admitted to the Medical Service (Service of Dr. Crockett) of the Massachusetts Memorial Hospitals at 11:15 P. M. of that day.

Examination showed an apprehensive, dehydrated, flushed, somewhat emaciated man. The temperature was 99.8° F., respirations 12, pulse 110. Conjunctivæ were markedly injected. Fibrillary twitchings of the calf muscles were visible, and there was marked carpopedal spasm. Trousseau and Chvostek signs were positive bilaterally. Knee jerks were hyperactive. The abdomen was spastic on

CHART 2 Laboratory data from Case 2

The blood chlorides and carbon dioxide combining power fell to normal within a few days, while the phenolsulphonphthalein values and blood nonprotein nitrogen took much longer to return to normal. It is interesting to speculate how much renal damage resulted from this complication.

In spite of the fact that this patient had partial pyloric obstruction, his vomiting ceased rapidly after chlorides were given, showing that his symptoms were due to alkalosis and hypochloremia and not to mechanical obstruction of his upper intestinal tract.

CASE 3 This patient is a fifty-eight year old man with a ten-year history of peptic ulcer for which he had taken alkaline powders and a moderately strict ulcer diet. In 1934, he contracted lobar pneumonia. During his convalescence he was put on an unrestricted diet which he continued after leaving the hospital. On discharge, his record shows that he had a slight trace of albumin, many coarsely granular casts and a moderate number of leucocytes in his urine.

He was free from symptoms until March, 1935, when he complained of gastric distress after meals. He returned to his previous diet, including the use of alkaline powders, and felt improved. The amount of alkalis ingested varied from 7 to 15 grams daily. He continued on this régime until the end of June, 1935,

pressure and there was some tenderness in the left upper quadrant. Peristalsis was visible in that region. The rest of the physical examination was negative.

Laboratory Data Red blood count was 5,180,000, hemoglobin 85 per cent. Urine was alkaline and contained a very slight trace of albumin. The sediment contained a few pus cells and rare blood cells, which disappeared in three days. But the urine remained alkaline and a slightest possible trace of albumin was still present when the patient was discharged. The nonprotein nitrogen of the blood was 70 mg per cent, uric acid 95 mg per cent, whole blood chloride 355 mg per cent.

The patient was given 1500 cc of physiologic saline solution intravenously. The following morning he received an equal amount of saline solution with glucose intravenously and this was repeated in the forenoon. He then seemed markedly improved. Gastric peristalsis was still visible in the left upper quadrant and a latent Trousseau sign was present in both arms. He was then put on a liquid diet of high caloric value which included 25 grams of sodium chloride daily. On the third day the nonprotein nitrogen of the blood rose to 80 mg per cent, urea was 66 mg per cent, uric acid fell to 5 mg per cent, and the blood chlorides had in

creased to only 360 mg per cent. Because of the kidney damage and nitrogen retention, the protein intake was restricted to a minimum. On this diet his laboratory findings rapidly returned to almost normal levels by the ninth day. On a chloride intake of 25 grams daily he was eliminating 1.5 grams. On the third day an alveolar carbon dioxide determination was done and showed 41 mm. Hg. On the eighth day of his stay in the hospital x-ray examination showed a constant filling defect in the pyloric region. Analysis of gastric contents showed normal fasting acid and normal response to

hot summer weather may have had some effect in the way of dehydration and chloride loss. Although anemia was not present to any degree he did show occult blood in his gastric juice on one analysis and in all stool specimens. It is interesting to follow the course of his laboratory studies, noting the parallelism in favorable response to therapy as marked by the drop in nonprotein nitrogen and the rise in the blood and urinary chlorides. Although no blood carbon dioxide determinations were done, there was undoubtedly some degree of alkalosis present at the start along with the other changes

CHART 3 Laboratory data from Case 3

stimulation but there was occult blood which was present also in the stools up to the day of discharge. He was advised that the lesion he had might possibly be a malignant growth and a laparotomy was suggested. Because of his marked clinical improvement the patient refused surgical operation and was released from the hospital. He then went to a private physician who advised resumption of a modified diet and alkaline therapy.

Six weeks later the patient came again to the hospital. A phenolsulphonephthalein test showed an excretion of 15 per cent in the first hour and 6 per cent in the second hour. The nonprotein nitrogen of the blood was 40 mg per cent. The urine showed a slight trace of albumin. He stated that he was taking only occasional small amounts of alkali. He had noticed that he was having some nocturia which was unusual for him. Nine weeks later he was seen again and at this time his phenolsulphonephthalein excretion showed a return of 35 per cent in the first hour and 15 per cent in the second hour. The blood nonprotein nitrogen was 40 mg per cent. The urine showed a slight trace of albumin. A flat x-ray film of the kidneys at this time showed no evidence of calcification in the genitourinary tract but there were deposits of opaque material in the gluteal muscles. (On questioning the patient stated that he had received some injections into the buttock five years previously. The Wassermann Kahn and Hinton tests however were negative.)

Comment

In view of the fact that renal injury was present one year previous to the onset of alkalosis one can suspect, although not prove that this may have been a factor in this case. Here we see the early symptoms simulating a recurrence of the ulcer developing slowly only to be aggravated by self-medication with increasing amounts of alkalies. The clinical course was obviously accelerated by the vicious cycle of vomiting. The nervous system manifestations were consistent with the severe

The peculiar curve of urinary chloride output is possibly due to two factors. First, although he was not first put on a daily intake of 25 grams of sodium chloride to which he responded a change to 5 grams was made on the sixteenth day which accounted for the drop in excretion. Beginning with the nineteenth day 20 grams daily were given. The lag in response to this amount might be attributed to compensation of a pre-existent chloride deficiency. Although the question may be raised that the vomiting in this patient (as in Case 2) may have been due to pyloric obstruction and not alkalosis with hypochloremia we feel that in view of the rapid improvement in response to chloride therapy there was probably only a minimal and insignificant obstruction. Very interesting to us were the follow-up studies which showed evidence of kidney dysfunction for at least four months. Whether this may be considered a sequela to the alkalosis or whether it was previously existent is a problem for speculation.

GENERAL DISCUSSION

These cases may be considered as representative types of alkalosis and hypochloremia, complicating the alkali treatment of peptic ulcer. Since complete laboratory studies are rarely performed on cases of peptic ulcer there are probably many instances of milder degrees of alkalosis not recognized clinically. If the possibility of this complication is kept in mind, we feel that it may explain some of the untoward symptoms encountered during the routine alkaline treatment of peptic ulcer. Since the chloride therapy is so simple and effective, and because of the danger of permanent renal damage or death early treatment should always be instituted.

Several investigators¹⁰⁻²⁵ have noted that calcification of the kidneys or tubular nephritis may follow persistent and untreated alkalosis. X-ray examination and renal function tests to detect these complications are advisable. We believe that occasionally it may be the cause of severe renal damage which develops after alkalosis.

SUMMARY

Three cases of peptic ulcer are reported in which treatment by the usual alkaline and Sippy régime resulted in the development of hypochloremia and alkalosis. This syndrome is known to follow persistent pyloric obstruction. It is not so well appreciated that it may also develop without organic obstruction if alkaline powders are given in the presence of impaired ability of the body to utilize basic ions. Persistent vomiting, renal disease, anemia, hematemeses, low salt intake, excessive perspiration, liver disease and excessive doses of alkalis can all impair the acid-base regulating mechanism. Persons with impaired renal function are invariably sensitive to small doses of alkalis. It seems probable that alkalosis can develop in persons with normal renal function, only if one or more additional factors besides excessive intake of alkalis are present. There is also evidence that persistent alkalosis can impair renal function by causing calcification or tubular nephritis. Nitrogen retention invariably accompanies alkalosis and hypochloremia. A characteristic clinical as well as laboratory picture develops which makes the diagnosis relatively easy. Sodium chloride therapy is highly successful.

AN UNUSUAL CASE OF NEVUS VASCULOSUS*

BY FRANK H. BAEHR, M.D.†

HEMANGIOMA or nevus vasculosus is found in several clinical forms and is commonly classified as (a) nevus flammeus, the superficial, nonelevated discoloration of the skin, usually called the port-wine type, and (b) nevus vasculosus, a deep-seated circumscribed or diffuse, elevated tumor formation. They are usually present at birth with cause unknown, and are said to occur more commonly in females.

Recently an unusual case of nevus vasculosus came under my care, which I believe is of interest.

G. F., an Armenian aged forty-three, complained that a tumor on his left forearm, present since birth, had doubled in size since it was hit with a hammer while he was at work six months before, i.e., December 14, 1931.

*Read at the Annual Meeting of the Hampshire County Medical Association, May 15, 1934.

†Baehr, Frank H.—Consulting Surgeon, Wesson Memorial Hospital and Springfield Health Department Hospitals. For record and address of author see This Week's Issue, page 1258.

Physical Examination. A well-developed and well-nourished white male. The general examination was essentially negative. Local examination of the left arm revealed a lobulated, bluish tumor on the volar surface of the forearm, extending from the wrist to the elbow (figs 1 and 2). When the arm was raised, the tumor mass decreased in size and palpation revealed a mass of tortuous vessels and blood sinuses. There was no evidence of superficial ulceration.

Treatment. On June 8, 1932, a preliminary injection of 0.5 cc invert sugar solution (75 per cent) was made just above the wrist. Subsequent injections into the blood vessels of the tumor were made at two to four day intervals, in doses up to 30 cc., until September 9, 1932, when the tumor mass had shrunk to about one-fifth its former size (fig 3). A short beveled 21 gauge needle was used. On June 24, 1932, 5 per cent sodium morrhuate was injected into three different points, 11 cc in one area and 22 cc in two different areas. The writer felt quite certain that the needle was in the venules on each occasion but a subsequent visit showed sloughs at the points where the 22 cc injections were made (fig 2). It was believed that

FIG 1

FIG 2

FIG 3

5 per cent sodium morrhuate was too strong a sclerotic agent to use in the injection treatment of hemangiomas. In all 590 cc. invert sugar were used

FIG 4

FIG 5

In the thirty five injection treatments. As the solution was being injected into the venules they became pink, remaining so for several minutes finally turning to a bluish grey. Following each injection the patient had a sharp cramp-like pain which extended from his left wrist to his left shoulder lasting for about five minutes.

Operation As all visible blood vessels of the tumor mass were sclerosed, it was considered advisable to remove the fibrotic mass. On October 5, 1932, at the Springfield Hospital (No. 107586), under ether anesthesia, an eight inch elliptical incision was made on the anterolateral aspect of the left forearm and the remains of the tumor mass were excised. An eight inch parallel incision was made on the anteromedial aspect of the left forearm, the skin edges undermined effecting a sliding closure of the elliptical incision with the use of dermal sutures. The patient had an uneventful recovery and could have been discharged from the hospital at the end of one week, but, due to poor family and financial conditions, he remained on the ward until the wounds had completely healed, a total of twenty-three days (figs. 4 and 5).

The patient was seen at intervals to January, 1933, when he was discharged as completely relieved, having full use of his left forearm, wrist and hand without any discomfort. He was again seen in September, 1933, and stated that, in the interim, he had been working and that his left forearm felt practically normal. Both forearms measured approximately the same in size.

Pathological examination by Dr. Frederick D. Jones: "Specimen consists of skin, subcutaneous tissue and blood vessels, measuring eighteen by eight cm. It is elliptical in shape, soft and shows, on the outer side, wrinkled epidermis. The inner side shows fat, connective tissue and vascular channels, giving it a dark red mottled appearance. On microscopic section, the epidermal layer is somewhat thickened. The vascular channels are widely dilated and supported by thin connective tissue septa. No capsule present." **Diagnosis:** Nevus vasculosus.

Light¹ has reported remarkable success with the use of sclerosing substances, as in varicose veins, in a case of a very large nevus vasculosus of the left ankle. Using this method of treatment, one must keep in mind the usual complications, as infection, emboli, and so forth, but with proper technique these are practically negligible. Ormsby² states that the most efficient method of treatment is with radium. Other means are refrigeration with carbon dioxide snow or liquid air, electrolysis and endothermy. All seem to agree, however, that there are occasions when no physical methods are advisable and even surgical procedure is not feasible, either because the tumor is too large or too deep, or the location is such that any amount of scarring would be disabling or objectionable. In such cases, it would seem that the injection of sclerosing chemicals should be considered.

On the average cavernous type, the combination of preliminary injection treatment and late surgery, after the tumor mass has been greatly diminished in size, seems to be a satisfactory procedure.

MEDICAL PROGRESS

PROGRESS IN ANESTHESIA IN 1935

BY RUSSELL F. SHELDON, M.D.†

RECOGNITION of his specialty by the constituted authorities is the natural desire of any practitioner who devotes his attention to a single branch of medicine. Two events in 1935 brought the culmination of this desire nearer to every American anesthetist.

In June for the first time in history, a combined meeting of the Canadian and American Medical Associations was held at Atlantic City, New Jersey. In the American Medical Association anesthesia is not given a definite subdivision, it is neither a part of surgery (surgeons specializing in anesthesia) nor of pharmacology and therapeutics, it takes its place, wherever one can be found, in the "Section on Miscellaneous Topics." But the Canadian Medical Association has a Section on Anesthesia. For the joint session, therefore, the Section on Miscellaneous Topics had to be considerably dressed up to share a program with the Section on Anesthesia of the Canadian Medical Association. With Dr.

John S. Lundy* of the Mayo Clinic as Chairman, and Dr. Philip D. Woodbridge of the Lahey Clinic, Boston, as secretary, the Section on Miscellaneous Topics made a very creditable showing. One hundred and eleven American anesthetists registered for this joint session. (For the section which met in the same hall in the afternoon, three were registered.)

The second event of 1935 was the start of a national plan for the certification of American anesthetists, sponsored by an active committee of the New York Society of Anesthetists, resulting in the award of the designation "Fellow in Anesthesiology" to those members of that Society who met the rigid standards set by the committee. This committee, headed by Dr. T. Drysdale Buchanan, deserves the highest praise, and the thanks of every American anesthetist for the careful and painstaking way in which it went about its work. Standards, conforming to those required in other specialties of medicine.

†Sheldon, Russell F.—Assistant Anesthetist, Massachusetts General Hospital and Massachusetts Eye & Ear Infirmary. For record and address of author see "This Week's Issue" page 1258.

*Dr. Lundy's address: The Clinical Use of Anesthetic Agents and Methods' was the Leader in the *Journal of the American Medical Association* for June 29, 1935 with the footnote: Section on Miscellaneous Topics Session on Anesthesia. No mention of the fact that the meeting was held jointly with the Section on Anesthesia, Canadian Medical Association is made.

icine, as laid down by the national boards were first adopted, then the committee certified its own members by these standards. After that it was in a position to certify others. The New York Society, founded in 1903, had members in twenty-three states, and was local therefore only in name, which has now been changed to the American Society of Anesthetists. The term Anesthesiology, includes anesthesia in all its forms, inhalation (gas) therapy and resuscitation. It is now felt, therefore, that the Fellows in Anesthesiology of the American Society of Anesthetists constitute a nucleus which at the 1936 convention of the American Medical Association may develop into the formation of a section on this subject and thus national recognition of anesthesia as a specialty. The American Medical Association Section on Surgery in business session at the Kansas City meeting appointed R. M. Tovell, Chairman, H. B. Stewart, and F. T. Romberger, to act in co-operation with representatives from the American Society of Anesthetists, and the American Society of Regional Anesthesia Inc. to investigate the possibility of formation of a National Board in Anesthesia, and report at the next annual meeting."

The British Anesthetists³ have united to form a group similar to the Fellows in Anesthesiology in this country by the award of a Diploma in Anesthesia, for which rigid standards, as manifest by written and practical examinations, are required. The Board for the award of the diploma meets in regular session twice each year.

Not only American anesthetists, but those all over the world mourn the death on February 22, 1935, of Elmer I. McKesson, one of the greatest teachers and missionaries of gas anesthesia, and inventor of the apparatus that bears his name.

In 1935 an increase in the interest in the specialty of anesthesia was evident. A local example will suffice to show this trend. The Boston Society of Anesthetists added seven new members, its constitution limiting membership to doctors of medicine who confine their practice to anesthesia; its mailing list, including physicians who are interested in anesthesia, but do not meet the constitutional requirement, has increased by twelve.

The keynote of the 1935 convention at Atlantic City was the teaching of anesthesia in order to supply the demand that exists among younger practitioners to learn more about it. It is becoming obvious that the practice of that branch of medicine known as anesthesia by others than physicians is to be checked not by legal means but by the supply of a superior, well grounded and trained medical personnel.

This process, of course takes time. "The acquisition of a mastery of anesthesia in art and in practice, with a thorough appreciation of the underlying physiology and pharmacology, involves for the average medical graduate an intensive training of not less than three years."

No attempt will be made to list all the articles on anesthesia which appeared in medical publications during 1935. As in the past, the writer readily admits that many of the best articles may have escaped his notice. However, a certain few are worthy of special mention either on account of the introduction of a new drug or principle, or on account of the classification or emphasis of methods and drugs already known.

The study of costal and abdominal respiration in relation to anesthesia, has been thoroughly carried out in dogs by Gesell and Moyer,¹ but as to its application to human beings the pneumographic studies now being carried out by Miller will give positive information. Alecock Berry and Daly² show the effect of many drugs on the pulmonary circulation. Stella⁴ and Wright,⁵ by experimental study, show that not only may the respiratory center be stimulated centrally, but peripherally by action on the sino-aortic node.

At Vanderbilt University, Emerson⁷ has done a vast amount of work on the autoxidation rate of surviving brain tissue in rats after the administration of almost all the current anesthetics and adrenin, in an effort to find the cause of anesthesia. There does not seem to be a uniform reaction applicable to all drugs. The same author⁸ presents a study on the effect of ether on the bioluminescence of the firefly, alive or dead, the operating room application of which seems rather far fetched.

Inhalation Anesthesia. Ether remains the standard for the judgment of anesthetic drugs by inhalation. In his new position as director of the division of anesthesia at Bellevue and allied hospitals, Roventine is concentrating on simple gas-ether anesthesia for a year, for he feels that it is essential that men new in the specialty be grounded in those agents. Kemp⁹ would be content to go no farther as he feels that with proper premedication ether is the ideal general anesthetic.

It must be recognized that there are other agents. Poe¹⁰ pleads for a more general use of ethylene which he feels has been wrongly condemned at many institutions. The increasing use of cyclopropane is reflected in the number of articles regarding it. Seevers, Di Fazio and Evans¹¹ offer a comparative study with ethylene on body saturation and desaturation. In this reviewer's opinion the best clinical presentation on cyclopropane appeared in this *Journal* from

the pens of Sise, Woodbridge and Eversole¹² of the Lahey Clinic "Because it apparently combines less toxicity with fairly powerful anesthetic action it could conceivably encroach on the field of all the other commonly used anesthetic agents" Because of the large amounts of oxygen (80-85 per cent) used with it, Sise,¹³ finds it especially valuable for thyrocardiac patients Rovenstine¹⁴ extols its use in thoracic surgery Romberger¹⁵ gives various points in technic and presents a chart on signs and phases A statistical study of postoperative morbidity in 2200 cases is presented by Schmidt and Waters¹⁶ It is always used with the soda lime filter Caution in its use is emphasized by all writers It is now easily obtainable from all manufacturers, one new development being the introduction by Squibb of two and six gallon "Amplons"

Trichlorethylene, ordinarily used in dry cleaning, nonexplosive and nonflammable, has been offered for anesthetic use A study of its pharmacology is published by Krantz, Carr, Musser and Harne,¹⁷ and on its clinical use in 300 cases by Striker, Goldblatt Warm and Jackson¹⁸ This drug, however, is hardly beyond the experimental stage

Vinethene, or divinyl oxide, has not apparently made great gains in popularity Bourne and Raginsky¹⁹ discuss its pharmacology, and Marvin²⁰ its clinical use

Rectal Anesthesia Shipway²¹ from England reports a series of 1600 administrations of avertin Though paraldehyde is much used by rectum as a basal anesthetic, the 1935 literature, except in obstetrics, provided no startling article

Intravenous Anesthesia The use of this method is also on the increase, Hale²² states "Administration of this type of anesthesia, even for periods of a few minutes, demands the services of two individuals, one to inject the solution, the other to provide for and supervise respiration

Intravenous anesthesia by means of the barbiturates is valuable, but potentially dangerous

Intermittent administration is essential to success" The best presentation on the use of evipal also appeared in this *Journal* a report from the Massachusetts General Hospital by Garrey and Cohn²³ Its value for brief surgical cases is stressed

Evipal, however, is a German preparation, and it is not surprising that other barbituric acid derivatives have been produced by American chemists Lundy²⁴ reports on the use of two new barbiturates, one of which, now called pentothal is likely in American institutions to displace the German product With the American product there is said to be less depression of respiration but to combat this, Lundy²⁵ has

combined 25 mg of coramine to each 1 cc of pentothal

Spinal Anesthesia There is as usual a vast number of publications on this subject, but, again in this *Journal*, Saklad²⁶ leads the field in an extremely valuable classification of drugs, methods and indications which definitely clears up a situation which to many has been decidedly confusing As to the drug used he says "Procaine should be the drug most often used under all ordinary conditions"

Sacral and Caudal Anesthesia From the Mayo Clinic, Campbell²⁷ presents the most thorough work on this subject

Regional Anesthesia The technic of nerve blocking for various orthopedic operations is described in detail by Lundy and Tovell²⁸ Zellhoefer²⁹ illustrates the increase in comfort and saving of time to patients, and of material to the hospital, in the healing of thyroidectomy wounds under regional anesthesia in comparison with local anesthesia

Premedication Calderone³⁰ shows that the value of premedication by morphine and the barbiturates is not in lessening the amount of ether used, as has generally been believed, but lies in the mental and physical relaxation they produce

Therapeutic Use From the Boston City Hospital³¹ has come some interesting work on the use of carbon dioxide and oxygen in cases of dangerous paralytic alcoholism In spite of the fact that some controversy has arisen there is no question that Robinson and Selesnick have saved lives by this therapy

Helium - Physiologic and pharmacologic studies by Barach³² on the use of this very light gas have led to its clinical use in cases of respiratory obstruction Used ordinarily with one-third oxygen, there is (1) a marked decreased effort in filling the lungs, (2) an increased volume of oxygen admitted to the lungs, (3) an increased velocity of air movement, and (4), a combination of these effects Barach,³³ and Maytum, Prickman and Boothby³⁴ show its almost miraculous effect in the treatment of severe intractable asthma

General Considerations 1 Explosions Finch,³⁵ from England, discusses the electrical ignition of gases, and methods for its prevention 2 The Thymus Superstition From the Children's Hospital in Boston, Hudson³⁶ questions the value of preanesthetic x-ray of the thymus routine in many clinics and also its treatment The title excellently expresses his opinion Waldbott³⁷ continues his allergic studies and concludes that the "Condition termed thymic death is a preallergic phenomenon similar to, or identical with, anaphylactic shock" Henson³⁸ upholds the older view, supported by

many pathologists that status lymphaticus is a reality, not a superstition.

For a single article giving the picture of anesthesia in 1935 Waters¹⁰ offers the best presentation with description of the carbon dioxide absorption technique and the use of cyclopropane.

Resuscitation The proponents of coramine are gaining. Reports from Kilian¹⁰ in Germany, and Wood¹¹ in this country show that there is value in this drug for respiratory stimulation. Maloney¹² has studied caffeine coramine and metrazol and Barlow¹³ a similar series of anaesthetics but at present the relative merits of these drugs have not been clarified. That they have some value however is clearly demonstrated.

Postoperative Complications Rapoport¹⁴ from the Beth Israel Hospital has the best report for the year on these complications following general and spinal anesthesia.

Obstetrical Anesthesia This is almost a situation of *tot homines, tot sententiae*. In an analysis of replies to a questionnaire sent to twenty-four clinics Gould and Hirst¹⁵ find a striking lack of unanimity of type and technique of obstetric analgesia and anesthesia. According to them "The ideal method has not been introduced." Locally, however, this reviewer feels that the "situation is well in hand and that expectant mothers are assured of safe and satisfactory amnesia and anesthesia.

As in the 1934 report thanks are again expressed to the Reading Report Group of the Boston Society of Anesthetists for its co-operation and assistance.

CASE 22251

PRESENTATION OF CASE

A fifty-five year old American business man was admitted complaining of abdominal pain.

The patient felt comparatively well until about a year before entry, when he "suddenly" developed pain in the left lower quadrant. The pain was constant and varied from a dull gnawing to a sharp stabbing character which was sufficiently severe at times to cause him to double up. There was no evident relationship to meals and at no time did it interfere with his rest at night. He was treated palliatively for about a month and the discomfort ceased as suddenly as it had begun. Subsequently he felt well until about four months before entry when he noted that he was losing weight. His weight at the onset was 155 pounds and at the time of admission 141. Concomitantly he observed a moderate loss of strength and a recurrence of the left lower abdominal discomfort. The latter was no longer so severe as it had been previously but he was always conscious of its presence, usually as a sensation of gurgling and distention. There was at no time associated diarrhea, melena, nausea, vomiting or fever—nor was there impairment of his appetite. His bowel movements had been costive for many years and he usually took mineral oil to insure a daily evacuation. There was no change in either the frequency or character of the stools.

Five years before coming to the hospital a physician told the patient that he had sugar in his urine. He was given a diet which caused his weight to decrease from 180 to 155 pounds.

Physical examination showed a well-developed and nourished middle-aged man in no evident discomfort. The skin was inelastic and there was general evidence of weight loss. The heart was normal. The blood pressure was 140/75. The lungs were clear. The abdomen was scaphoid in appearance and peristaltic waves were visible near the umbilicus. Hyperperistalsis was audible. Deep in the left iliac fossa a questionable mass was palpated. No details were noted.

The temperature, pulse, and respirations were normal.

Examination of the urine was negative. Examination of the blood showed a red cell count of 5,480,000, with a hemoglobin of 90 per cent. The white cell count was 10,200, 72 per cent polymorphonuclears. Repeated stool examinations showed no evidence of occult blood. The nonprotein nitrogen of the blood was 32 milligrams.

A barium enema met with obstruction just beyond the rectosigmoid junction. After some time a small amount of barium trickled through the markedly narrowed sigmoid. The narrowing involved an area of about 10 to 12 centimeters, the most pronounced narrowing being 5 centimeters in length. Proximal and distal to the narrowing, definite diverticula were visible. The mucosa of the upper portion of the narrowed region was swollen but intact, beneath the lesion the mucosa was incompletely demonstrated. On the following day another barium enema was administered. After the patient was given amyl nitrite the proximal two-thirds of the narrowed area dilated somewhat and there were definite diverticula visible in this region as well as at the rectosigmoid junction. The distal 4 centimeters of the narrowed lesion did not dilate. Longitudinal lines running through this area had the appearance of mucosal folds. The remainder of the colon and appendix gradually filled.

At the end of one week a laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR E PARKER HAYDEN This is a history of the onset of left lower quadrant pain which persisted until some sort of palliative treatment was instituted. One would assume that this consisted in the institution of a liquid or soft diet, possibly with the use of mineral oil, thus eliminating what were presumably obstructive symptoms. On the other hand, if the pain really was constant, that fact would suggest that it was not a case of obstruction alone but that there was a low-grade inflammatory process associated with it. All of the symptoms were relieved, by the institution of this palliative treatment, for a period of about eight months during which time no blood was noted and there was no recurrence of the symptoms.

The x-ray data in this case are very complete and would seem to clear up the diagnosis, though this may not be so. The extent of the narrowing was 10 to 12 centimeters, which is a little long for a malignant narrowing in that locality in most instances. The most pronounced narrowing was 5 centimeters in length. Definite diverticula were visible both above and below the narrowed area. The mucosa above was swollen and intact, whereas below the constriction it was incompletely demonstrated. The re-

port does not say whether it was thought to be normal

Thus we know the patient had diverticula present, and one would assume without much question that there existed some degree of diverticulitis, apparently not acute but probably the sort of chronic diverticulitis that produces a narrowing of the lumen and a thickening of the whole bowel wall without any very acute inflammatory symptoms. The fact that there occurred some relaxation with amyl nitrite suggests that a good deal of the narrowing was due to spasm. The mucosal folds above the narrowed area were normal. When there exists an inflammatory structure for that length of time one is apt to find ulceration of the bowel wall above the narrowed area. Apparently that was not the case here. Simple strictures of the bowel are quite uncommon in that region. They are usually lower down. The only noninflammatory strictures I have seen at that level were produced by radium treatment to the cervix or by diverticulitis.

The amyl nitrite failed to relax the area of most pronounced narrowing, which was at the lower end. It is possible that this individual had a carcinoma superimposed on diverticulitis. The loss of weight must be explained in some way. The lack of blood in the stools is against neoplasm but nevertheless does not absolutely exclude it. Another possibility is that he might have had a very small carcinoma in the sigmoid which had intussuscepted, producing the somewhat unusual barium enema picture. That may be the reason the mucosal folds did not show up in the lower part. It occasionally happens also that one sees an adenocarcinoma which does not involve the mucous membrane but is entirely perirectal. I have happened to see two such cases, with a simple narrowing of the bowel and no interference with the mucosal pattern. That may possibly be the situation here. One must also think of the possibility of a lymphoma of the rectum, another tumor which may not disturb the mucosa greatly. I think it is difficult to say with certainty just what went on here, but we have a barium enema demonstrating the presence of diverticula, and the most logical conclusion would be to say that the patient had a very low grade chronic diverticulitis, quite possibly with a carcinomatous degeneration in one section of it.

DR. AUBREY O HAMPTON. I think this was an exceptional case. I know what the patient had and I think about nine times out of ten we are able to give a little more accurate final diagnosis than we did on this. The note was made that we would like to re-examine the patient after two or three weeks to see if this lesion had changed, hoping that if it was diverticulitis it would, and if it was cancer it would not. Here is the defect that was described as

5 centimeters in length and rigid, that is, there was no muscular activity, nor did it relax after amyl nitrite. When Dr. Schatzki did the examination he was fairly certain the patient had had diverticulitis and he was worried about the mucosa in this area. Dr. Holmes and I saw the films with Dr. Jones and we thought that one end of the lesion looked like carcinoma and the other end did not, which made it very difficult to exclude carcinoma. These lines do look like mucosal folds and yet scirrhous carcinoma will have the same lines in it sometimes. So we were not justified in saying that the patient just had diverticulitis and we were not justified in saying he had carcinoma. We had to admit that this was a case where we could not differentiate diverticulitis and carcinoma. I believe we can usually differentiate these two lesions much better than the surgeons.

DR. DANIEL FISKE JONES. This is a very interesting case in that it was impossible to make a positive diagnosis, and yet from various things it was quite evident that the patient should be operated upon. Here was a man complaining of very little except weakness and some abdominal discomfort which we eventually decided was really considerable pain. It was evident from this man's appearance and manner that he made light of all his symptoms. The symptoms had been going on for at least a year, starting with pain in the left lower quadrant. He improved but later had much rumbling of gas and pain in the lower abdomen. The character of the pain, as gathered from the history suggested obstruction. He had been losing weight for four months. He looked thin and uncomfortable, and had had much discomfort in the last two months due to pain in the lower abdomen and difficulty in getting the bowels to move.

With the tender mass in the left lower quadrant the first thing thought of was a diverticulitis. We then went ahead and tried to prove that it was not a diverticulitis. There was no blood in the stools. Patients with diverticulitis and without carcinoma have blood in the stool in about 6 per cent of the cases. It is therefore only reasonable to assume when the roentgenologist makes a diagnosis of diverticulitis and blood is present in the stool that it will be diverticulitis in only about 6 per cent of those cases. You must operate in such cases to make the diagnosis positive. In spite of the fact that there was no blood in the stool in this case the roentgenologists could not say that there was no carcinoma. When men like Dr. Holmes, Dr. Hampton, and Dr. Schatzki say that the condition is probably diverticulitis but that they do not feel certain about the lower end of the deformed area you must operate. In addition to this the patient was much obstructed, had lost weight and looked bad. Exploratory operation was easy to advise under such circum-

stances We did not have to decide definitely whether it was diverticulitis, in spite of the fact that we thought he had diverticulitis We went ahead because of the loss of weight and the general symptoms

We operated and found a hard mass down in the left side of the pelvis firmly attached to the left side of the base of the bladder, so much so that I had to take off the peritoneum and some of the muscle of the bladder to get it out It was so hard that I could not possibly tell by pressure whether it was malignant disease or an inflammatory process, but there again I did not have to make much of an effort to tell which it was I felt that it ought to come out, first because of the symptoms, and secondly because he was likely to have a fistula between the bladder and the diverticulitis, if it was diverticulitis So there again we had an easy time deciding what to do, and resected the colon When we got it out it was still so hard that we could not tell and had to have Dr Hartwell come to the operating room to look at it He cut it open and said that there was no erosion of the mucous membrane and that he thought it was simple diverticulitis You see, the thing was rather difficult to decide positively all the way through this case He was unwilling to say whether there was malignancy until he had had a microscopic examination, which he did The report came back that it was nothing but inflammatory tissue

I think that that is the way you have to treat these cases of diverticulitis It is not an easy question to decide, for the roentgenologist, the surgeon, or the pathologist cannot always make a definite diagnosis until a microscopic examination has been made One cannot always depend upon the x-ray examination alone

DR HAMPTON Just nine times out of ten

DR JONES How would you like to be the tenth man? He is the one whom we have to look out for In diagnosis you must not depend upon any one thing but must use every possible aid to diagnosis and then remember that if you do not operate and the condition turns out to be a carcinoma, you have done a great harm

I have a letter from the doctor who referred this case to me He says "The sigmoid was examined with the sigmoidoscope and a marked constriction found about eight inches from the rectum" I should like to comment upon this statement, because to draw the correct conclusions from a proctoscopic examination is often very difficult To say that there is a stricture is often an error, for the bowel held kinked will often appear to be constricted In this particular case the bowel was kinked and held in that position by the adhesions It would have been impossible to see the real zone of narrowing in this case because after the mass had been

freed it could be brought into the wound, making it so high that it could not be seen with the proctoscope The diagnosis of diverticulitis can be made only very rarely with the proctoscope If the proctoscope had been used to feel with I believe that the fixed mass could have been felt through the rectal wall Even with a carcinoma at the rectosigmoid junction the growth cannot always be seen, for the contraction of the growth frequently makes a kink and fixes it so that it cannot be seen with a straight instrument To see discharge or flecks of blood coming from above the end of the proctoscope is frequently of value in making a diagnosis of carcinoma, but occasionally there will be slight bleeding from a region of diverticulitis, often from a small polyp or due to the inflammatory process in the bowel wall

The sigmoid was resected, an end-to-end suture done and the man left the hospital today

PREOPERATIVE DIAGNOSES

Diverticulitis of the sigmoid
Malignancy?

DR. E PARKER HAYDEN'S DIAGNOSIS

Chronic obstructive diverticulitis with possible carcinomatous degeneration

PATHOLOGIC DIAGNOSES

Chronic localized colitis
Diverticulitis?

PATHOLOGIC DISCUSSION

DR TRACY B MALLORY This man's lesion was without any question inflammatory and not neoplastic On the other hand, it was a bit more difficult to say exactly what sort of inflammatory lesion it was When Dr Hartwell first examined the specimen he found one shallow pocket with a broad mouth containing a fecolith, so that one must admit the presence of a diverticulum On the other hand, it was not the type of diverticulum that is apt to lead to diverticulitis These very shallow broad-mouthed ones are quite common and do not ordinarily cause trouble It is the deep, narrow-mouthed ones that usually result in symptoms We were not able to demonstrate any of that sort There was a quite diffuse inflammatory process involving three or four centimeters of the gut with a diffuse fibrosis, marked mononuclear reaction and a little ulceration in the mucosa but in the specimen which we received no very characteristic diverticulum

DR HAMPTON Is that at all unusual?

DR MALLORY Yes Ordinarily there is no particular trouble demonstrating diverticula, if they are there It is possible he had a diverticulum which spontaneously cut itself off months ago so that we could no longer find it

DR HAMPTON Is this diffuse, deep thickening

ing and hardening of the whole bowel common, that is, is not diverticulitis a unilateral lesion ordinarily instead of annular?

DR. MALLORY I think we have seen annular involvement but usually when it was annular it was due to fibrosis around the gut rather than actual scarring throughout all layers.

DR. HAMPTON The musculature is usually intact except at the site of the diseased diverticula?

DR. MALLORY Yes.

DR. JONES I think that there must have been a diverticulum in that hard mass because inflammatory tissue will not stay so hard unless there is something to keep it there. There must have been a foreign body or abscess to keep it as hard as it was. If it softens up it will be thickened but not such hard tissue.

CASE 2222

PRESENTATION OF CASE

A seventy-three year old white janitor was admitted complaining of jaundice.

About three weeks before coming to the hospital the patient began to have daily episodes of burning pain in the epigastrium with sour eructations. He produced relief by inserting a finger into his mouth to initiate emesis. The vomitus contained ingested food and watery fluid and was never yellow, green tarry or bloody. These attacks usually occurred at night and caused the patient to awaken. For about one week he took baking soda after vomiting which relieved his discomfort sufficiently so that he could sleep. There was lack of appetite and spontaneous curtailment of diet. Ten days before entry he first noted slight nontender swelling of his ankles. About the same time his urine became dark brown in color and a neighbor called his attention to the fact that he was jaundiced. He became progressively weaker and noticed that his weight had diminished from 165 to 152 pounds in eight months. There was no pruritus and the color of the stools was not noted. His bowel movements occurred at daily intervals but currently were lessened in amount.

The patient had taken small quantities of whiskey daily for about fifty years. He had always been well until three years prior to admission, when he noticed some loss of appetite and energy.

Physical examination showed a well developed and nourished icteric man in no discomfort. The left pupil was slightly irregular and there was marked sclerosis of the retinal arterioles. A small left epitrochlear node was palpated. The chest was kyphotic, barrel shaped and hyperresonance was elicited generally. The lungs were otherwise negative and the heart was nor-

mal. The blood pressure was 140/70. The abdomen was slightly distended but no shifting dullness was found. The liver edge extended three fingerbreadths beneath the costal margin. No areas of spasm or tenderness were noted. There was slight pitting edema of the ankles. The knee and ankle jerks were absent as was vibratory sense in the region of the ankles. Positional sense was good.

The temperature, pulse and respirations were normal.

Examination of the urine showed a slight trace of albumin and a large amount of bile. The sediment was negative. The blood showed a red cell count of 4,270,000 with a hemoglobin of 75 per cent. The white cell count was 10,300, 80 per cent polymorphonuclears. A stool was brownish gray and gave a negative reaction to the guaiac test. A Hinton test was negative. The nonprotein nitrogen of the blood was 30 milligrams and the chlorides 101 cubic centimeters. The icteric index was 75 and the van den Bergh showed 33.3 milligrams bilirubin. A blood cholesterol was 297 milligrams. The vomitus occasionally gave a positive reaction to the guaiac test. The sedimentation rate was 16 millimeters per minute.

A flat x-ray film of the gallbladder region showed no stones. Examination of the gastrointestinal tract showed a normal esophagus. The stomach was dilated and contained considerable fluid. Peristalsis was unusually vigorous. The duodenal cap was dilated and there was a pressure defect with constriction at its apex. The cap filled readily but no barium passed beyond its apex. At the end of six hours the stomach still contained about 98 per cent of the barium and there was a minute amount present in the jejunum. There was no definite evidence of increase in the duodenal curve.

On the third day a plum sized rounded mass was felt in the right upper quadrant just above the umbilicus. Two days later constant gastric drainage was instituted and on the tenth day a laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR. JOHN D. STEWART We are told that the burning pain in the epigastrium with sour eructations was relieved by vomiting. This fact is suggestive of interference with the normal emptying of the stomach, an inference further supported by the description of the vomitus as consisting of recently eaten food and watery fluid. Furthermore, the vomitus is reported as never containing bile, an important point in that it helps us in localizing the obstructive lesion we are beginning to suspect. Either bile is not gaining access to the duodenum, or else the duodenal lumen as far as the papilla of Vater is no longer in continuity with the stomach.

About ten days after the onset of the epigastric pain, swelling of the ankles and obstructive jaundice developed. Such evidence of retention of bile pigments as the presence of bile in the urine and jaundice helps to focus our attention more closely on the region of the proximal third of the duodenum and the extrahepatic biliary tract. The color of the stools was not noted unfortunately, for the presence or absence of bile in the stools in this case is an important point. The patient is recorded as having taken small quantities of whiskey daily for about fifty years, and as having noticed a rather indefinite loss of health three years before admission. Such a statement requires us to consider the possibility of cirrhosis of the liver of the portal type, and the not infrequent association of such cirrhosis with primary carcinoma of the liver.

The more significant points in the physical examination seem to be jaundice, distended abdomen in which shifting dullness was looked for but not found, liver edge palpable three fingerbreadths below the costal margin, slight edema of the ankles, and the neurological signs of absent knee jerks, ankle jerks and tibial vibration sense. Evidently if the patient has cirrhosis of the liver he has no considerable degree of obstruction to portal circulation, for there is no demonstrable ascites, only slight edema of the ankles, and no history of melena or hematemesis. The loss of vibration sense at the ankles and absent tendon reflexes, one sees in lesions of the spinal cord, such as combined system disease. There is nothing else in the record to suggest pernicious anemia.

Among the laboratory findings are noted bile in the urine, mild hypochromic anemia, a stool color suggestive of absent bile, markedly elevated icteric index and van den Bergh, moderately elevated blood cholesterol, vomitus giving a positive test for occult blood, and an increased sedimentation rate. These pieces of evidence help us only in confirming our suspicion of a lesion producing obstruction of the extrahepatic biliary tract and interfering with the continuity of the upper gastrointestinal canal.

The radiologist comes to our help by demonstrating a dilated hypertonic stomach and obstruction at the apex of the duodenal cap. There was marked gastric stasis despite the vigorous peristalsis.

On further abdominal palpation a small epigastric mass was felt and after reducing the size of the stomach and emptying it thoroughly by gastric drainage laparotomy was performed.

The differential diagnosis, as should always be the case, turns on the most indubitable, the objective evidence. The patient has a lesion which obstructs both the common bile duct and the second portion of the duodenum. In addition there is a palpable epigastric mass. In this

case we do not hesitate to postulate neoplasm as the most likely cause of such obstruction. Where is the growth primary, in the liver, the gallbladder, the common duct or ampulla of Vater, the duodenum, the head of the pancreas or the pylorus? Has the patient a lesion of retroperitoneal tissues, such as lymphosarcoma, invading the region in question? Carcinoma of the transverse colon manifesting itself in duodenal obstruction would be a bizarre lesion. To consider the possibilities—the likelihood of primary carcinoma of the liver is greatly reduced by lack of evidence for cirrhosis of the liver. Obviously those in charge of the cases were thinking of cirrhosis of the liver, but they seem to have found little evidence of portal stasis, and no esophageal varices were discovered by x-ray. The likelihood of primary carcinoma of the gallbladder is somewhat reduced by failure to show gallstones by x-ray and absence of historical indications of gallbladder disease, for carcinoma of this organ is commonly associated with gallstones and chronic cholecystitis. A lesion in the common duct itself is a possibility especially at its duodenal extremity. Such a lesion, however, should produce jaundice early and duodenal obstruction late. It seems to me that much must be made of the fact that the lesion in this case must have been silent for a considerable period, for when symptoms first appear it is extensive enough to obstruct both duodenum and common duct almost completely. We logically turn then to consideration of a lesion primary neither in common duct nor duodenum, and most likely under the circumstances is carcinoma of the head of the pancreas.

CLINICAL DIAGNOSES

Carcinoma of the pancreas
Arteriosclerosis
Emphysema
Coronary thrombosis?

DR JOHN STEWART'S DIAGNOSIS

Carcinoma of the head of the pancreas

ANATOMIC DIAGNOSES

Accessory annular process of the pancreas
Carcinoma of the head of the pancreas with obstruction to the duodenum and the common bile duct, and metastases to the retroperitoneal glands and the liver
Dilatation of the bile ducts
Operative wound. Posterior gastroenterostomy, cholecystgastrostomy
Hemoperitoneum, slight
Pleuritis, chronic fibrous, bilateral
Bronchopneumonia, bilateral, lower lobes
Pericarditis, chronic fibrous, slight
Arteriosclerosis, aortic and coronary, moderate

Hyperplasia of the prostate
Cystitis, acute, slight.
Pyelitis, acute, left
Icterus

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY: This patient was transferred to the surgical service, where he was operated on by Dr. Allen. A carcinoma of the head of the pancreas was found which constricted both the duodenum and the lower end of the common bile duct. This left the surgeon only two alternatives, to back out without doing anything or to attempt the rather desperate maneuver of a double operation—a cholecystogastrostomy to drain the biliary system plus a gastroenterostomy to relieve the duodenal obstruction and to shunt the bile along into the intestinal tract. The latter procedure was, correctly in my opinion, decided upon and carried out. Many cancers of the pancreas in elderly individuals are slowly growing and palliative operations of this type will, if successful, often return the patient to excellent health for periods of two, three occasionally as many as five years.

During the operation the patient's blood pressure fell alarmingly. A transfusion was given on the table and his condition improved enough to allow the operation to be finished and he did not appear in bad shape on his return to the ward. That evening about 9:00 p.m. he developed a peculiar attack of syncope with accompanying cyanosis but no venous distention.

At ten o'clock the blood pressure suddenly fell from 120/80 to 70/45 and shortly afterwards to 55/32. There was no sweating and the pulse though of poor quality did not rise above 100. Intravenous glucose and the usual stimulants failed to revive him and he died about five the next morning.

The postmortem examination showed a carcinoma arising in what appeared to be an accessory lobe of pancreatic tissue lying chiefly to the right and behind the duodenum with some invasion of the lower part of the head of the pancreas proper. This, I believe, explains the rather unusual picture of obstruction of the second portion of the duodenum by a cancer of the pancreas. The lower end of the common duct was involved and the biliary tract above the point of obstruction was markedly dilated. The liver was not enlarged (it had been pushed down by the low diaphragm resultant upon his barrel chest), but on section showed numerous metastases.

The cause of the final, rather dramatic collapse was not determined. There was some free blood in the peritoneal cavity but it was estimated at only a few hundred cubic centimeters. The coronary arteries showed no thrombosis, in fact very few atheromatous plaques considering his age. The pulmonary arteries were negative. We did not have permission to examine the head so a cerebral complication cannot be ruled out. My inclination, however, is to consider it a form of postoperative shock even though appropriate therapy proved unavailing.

The Massachusetts Medical Society

THE ANNUAL MEETING

For three days June 8, 9 and 10, Springfield opened its doors and generously entertained 909 Fellows of the Massachusetts Medical Society who were registered and about fifty ladies.

These figures do not show the exact attendance, for some members did not register and therefore are not recorded.

The pleasant weather together with the attractive programs and ample publicity by the Committees explains this large attendance.

Although the Auditorium, where the exhibits and scientific sessions were provided with space, had been the location of an active political convention up to within a few hours of the advertised program of the Society, there were only minor delays and everything was in working order early on the first day of the meeting.

All of the section meetings and hospital clinics were well attended and the scientific exhibits called forth enthusiastic commendations for the scope and quality of their demonstrations.

The *Journal* respectfully suggests that the custom of awarding prizes for especially worthy scientific exhibits would be appreciated.

The attendance at the Shattuck Lecture filled all available space in the ballroom of the Hotel Kimball. Dr. Blumer made the subject of Trichinosis of practical interest to physicians and covered the scientific aspects of the disease completely. His paper appears in this issue of the *Journal*.*

The Council Meeting was attended by a large and representative group and the routine business was dispatched promptly. The report of the Committee on Public Relations was of unusual importance and its presentation was given careful and sustained attention. Because of the advanced stand taken by the Committee relating to prepaid hospitalization and the economic features of other forms of practice, it was feared that differences of opinion would be expressed which might lead to controversy. Contrary to expectations the Council almost unanimously endorsed the recommendations submitted. This action is a well-merited tribute to the careful study given to questions before the profession by the Committee.

By vote of the Council these matters will continue to receive the careful attention of this Committee.

By reason of certain important matters before the Committee on Ethics and Discipline which were unsettled, Dr. David Cheever asked for an executive session, which was accorded, and he then submitted a detailed report of the arduous and perplexing work of the Committee. He asked for careful consideration of the important questions before the Society with the hope that constructive opinions would be forthcoming and thereby lead to sound conclusions and appropriate action.

Following the reports of the Standing Committees and discussion of the matters presented, the Chair called for the report of the Nominating Committee. The following names were presented: President, Dr. Charles E. Mongan, Vice President, Dr. Channing Frothingham, Secretary, Dr. Alexander S. Begg, Treasurer, Dr. Charles S. Butler, and Orator, Dr. J. W. O'Connor. By unanimous vote the Secretary was directed to cast one ballot for these severally designated persons. The unanimous and enthusiastic vote is a demonstration of approval of the Committee on Nominations.

To new members of the Society attention is called to the *Journal* of June 13, 1935 where may be found the portraits of the four re-elected officers. To the general membership, no introduction is necessary.

All of the details of the meeting of the Council

oil, except the matters dealt with in executive session will be published in the Secretary's record soon to appear.

The Annual Dinner was attended by over three hundred Fellows and guests. Seated at the head table President Morgan was in the center. On his right were Reverend Father Michael J. Ahern, Professor of Geology at Weston College, Vice President Dr. Channing Frothingham, Dr. W. R. Morrison, Chairman of the Committee of Arrangements, Dr. Allen G. Rice, Chairman of the Local Committee of Arrangements, Dr. Walter P. Bowers of *The New England Journal of Medicine*, Mrs. Emma Brigham, member of the Legislature from Springfield, Mr. Henry Martens, Mayor of Springfield, Dr. Royal Watkins, member of the State Board of Registration in Medicine, Dr. Frederick B. Sweet of Springfield and Dr. Henry Jackson Sr., of Boston.

On the left of the President were the Very Reverend Percy T. Eldrop, Dean of Christ Cathedral of Springfield, Father O'Connor of Northampton, Dr. A. S. Berg, Secretary of the Massachusetts Medical Society, Dr. Charles S. Butler, Treasurer of the Massachusetts Medical Society, Dr. John M. Bunne, Ex-President, Dr. H. G. Stetson, Ex-President, Dr. Enos Bigelow, Ex-President, Dr. Roger I. Lee, Trustee of the American Medical Association and Dr. Walter A. Lane, Vice Chairman of the Committee on Public Relations.

The after-dinner speaking was opened by the introduction of his Honor the Mayor who cordially welcomed the Society to Springfield with assurances of the freedom and protection of the city for the members of the Society and on invitation to return to Springfield for future meetings.

Mrs. Emma Brigham demonstrated her interest in medicine by stating that she is a registered nurse, a graduate of the Massachusetts General Hospital Training School for Nurses and also that of the McLean Hospital and more particularly because she married a physician. She gave a very interesting account of her work in the legislature in association with others in the final passage of the bill relating to medical education which was passed in the present session.

Dr. Roger I. Lee gave a graphic account of the purposes and functions of the American Medical Association with the assurance that the relations of the State Society and the National organization were cordial and co-operative in serving the people of this country and promoting the best interest of the medical profession.

The Reverend Father Ahern gave a very interesting account of his participation in a ten thousand mile journey covering important cen-

ters of the United States in association with Rabbi Morris S. Lazarus and the Reverend R. Clinchy for the purpose of promoting the spirit of tolerance among the several religious denominations. Beginning with the conditions in those countries where there had been a union of church and state and the gradual separation of these organizations so far as control of one over the other is concerned, he defined the purpose of the early settlers of our country and fundamental principles which have given freedom to the individual to adopt that form of religious belief consonant with his own interpretation of his relation to God and the needs of his spiritual nature.

Father Ahern found a ready response to the teaching of this trio throughout the country and in an inspiring appeal urged us all to come to a realization of the necessity of unselfish love one for another in the human family which would overcome prejudices and promote the welfare of the country.

Those who were unable to attend this occasion missed an inspiring appeal to the better element in human nature presented by a distinguished public speaker.

The general meeting of the Society was the closing feature of the program.

The Secretary presented the usual statistical report showing a steady growth of membership. The report of a committee to which a matter for disciplinary action was referred at the last Annual Meeting required resort to an executive session. After emerging from this, the President read his address in which the condition of the Society and accounts of important actions carried on during the year were set forth.

The Annual Discourse delivered by Dr. Reginald Fitz followed and was the final exercise in the official program.

In addition to a well prepared historical account of the gradual evolution of the important contribution to progress in this country brought about by the adaptation and utilization of the great discoveries in science and art, he showed how medicine had profited by better transportation and the adoption of many forms of electricity in dealing with disease.

His address appeared on page 1178 of the *Journal* of June 11.

Before the close of the meeting Dr. Morrison, Chairman of the Committee of Arrangements, in behalf of the Society voiced the grateful appreciation of the convention for the hospitality extended by the City of Springfield, the courtesy of the hotels and the very essential and efficient co-operation of the several local committees.

In later issues of the *Journal* the papers and discussions submitted to the several sections will

be published The reports of the Proceedings of the Council and the Society will appear in our columns as soon as they are put into form by the Secretary, and should be given careful study

This Annual Meeting marks another milestone in the history of the Massachusetts Medical Society

THE BOSTON NURSERY FOR BLIND BABIES

CITIZENS of Massachusetts early recognized the responsibility of the community for the care and training of the blind, and for years our State has enjoyed an enviable reputation in this respect Years ago the Perkins School for the Blind was established, followed by the Kindergarten for the Blind in 1887 For ten years Isabel Greeley taught in the Kindergarten, during which time she came to realize that blind children and children with defective vision must receive intelligent care and training long before the kindergarten age, in order to prevent the development of mental and further physical handicaps

From her ideas and from her determination came, in 1901, a Nursery for Blind Babies in an old private residence on Fort Avenue in Roxbury To this, from homes of poverty and distress, came babies and young children with all degrees of blindness, from total, already incurable blindness, to partial and curable defects in vision About twenty-seven years ago the new Nursery, capable of caring for twenty-five children, was built on South Huntington Avenue Two years ago a Nursery School was organized in order that the preschool children might have the benefit of the same kind of Nursery School training that is available to children with normal vision

There were no precedents or methods of training available for the carrying on of this work It was again a pioneering task, but for two years Nursery School methods have been adapted to the capabilities of blind children—marching, singing, building, painting, gardening, indoor and outdoor games—so that at the average age of six years these children may move on to the Perkins Kindergarten

The history of this specialized educational effort, combined with the story of the importance and amazing results of early training of the blind is told in an engaging little pamphlet prepared as a guide to the care and training of the preschool blind child, and distributed by the Boston Nursery for Blind Babies Reading it awakens one's interest in the problem and one's admiration of the way it is being met

MISCELLANY

MAINE NEWS

WATERVILLE SENTINEL HEADLINE SAYS, "WAR ON CANCER STARTED IN MAINE"

Mrs William Holt of Portland has been appointed State Commander of the Woman's Field Army against Cancer for the State of Maine, by Dr C C Little, managing director of the American Society for Control of Cancer

A State Committee has been formed which will provide the free service of a pathologist, a radiologist, a roentgenologist and a surgeon

Clinics have been organized at Lewiston, Waterville and Portland

Vice-Commanders of the Maine Women's Field Army are Mrs. B. O. Cushman of Lewiston and Mrs. Magnus Ridlon of Bangor.

The State Committee Chairman is Dr. Mangus Ridlon of Bangor and the advisory and executive committee is composed of Dr. Joseph Sennell of Lewiston, Chairman; Dr. John Johnson of Bangor; Dr. Theodore Hill of Waterville; Dr. Edward H. Risley of Waterville; Dr. William Holt of Portland; Dr. George Coombs of Augusta; Frank Stillman of Bangor; Mrs. Ridlon; Mrs. Cushman; Mrs. Holt; Clarence Crosby of Dexter; Samuel Stewart of Lewiston; Dr. George Averill of Waterville; Bishop J. E. McCarthy of Portland; and Robert Brann of Portland.

GRADUATE TEACHING CLINICS

Central Maine General Hospital, Lewiston, Maine. On May 22, Dr. Otto Hermann of Boston conducted a clinic on the treatment of fractures.

The following addresses have also been scheduled: June 11, Dr. Joseph Pratt of Boston, Subject: "Neuroses."

Dr. J. Schloss on "Newer Methods in Diagnosis of Gastric Diseases."

June 12, Onting at Bethel Inn. Paper by Dr. S. J. Thannhauser in the evening. Subject: "Functional Tests in Dietary Treatment of Liver Disorders."

EDWARD H. RISLEY, M.D., Reporter

AN HONOR TO DR. LAHEY

At the meeting of the American Society for the Study of Gout in Chicago, June 10, 1936, Dr. Frank H. Lahey was elected to the position of President Elect.

AN HONORARY DEGREE AWARDED TO DR. JOHN H. WAITE

At the recent commencement exercises of Bucknell University, Lewisburg, Pennsylvania, the honorary degree of Doctor of Science was awarded to Dr. John Herbert Waite of Boston.

MORTALITY RATES

Telegraphic returns from 86 cities of the United States with a total population of thirty-seven millions for the week ending May 23 indicate a mortality rate of 11.7 as against a rate of 11.6 for the corresponding week of last year. The highest rate (21.5) appears for Hartford, Conn., and the lowest (5.5) for South Bend, Ind. The highest infant mortality rate (20.4) appears for San Antonio, Texas, and the lowest for Lynn, Mass. Miami, Fla., New Haven, Conn., Seattle, Wash., South Bend, Ind., and Wilmington, Del., which reported no infant mortality.

The annual rate for 86 cities is 13.4 for the twenty-one weeks of 1936 as against a rate of 1.5 for the corresponding period of the previous year. The rates for February, March, April, and most of May

account for the higher figures for these twenty-one weeks. The rate for the last week of May is almost as low as that of the corresponding date of last year.

SUMMARY OF DEATHS AND DEATH RATES (ANNUAL BASIS) FROM AUTOMOBILE ACCIDENTS PER 100,000 ESTIMATED POPULATION FOR 86 CITIES FOR CORRESPONDING PERIODS OF 1936 AND 1935

	Week ending		First 21 weeks	
	May 23 1936	May -5 1935	1936	1935
Total deaths	145	155	2,955	3,418
Death rate	20.3	21.7	19.7	22.7
Deaths due to accidents in city	103	119	2,238	2,769
Death rate	14.4	16.6	15.2	18.4

INFORMATION RELATING TO PUBLIC RELIEF FOR ILLNESS

In the May Bulletin of the Boston Council of Social Agencies, there are records of medical service which have an important relation to all relief expenditures.

The four psychiatric and guidance clinics started to report monthly to the Council of Social Agencies in January, 1936. The figures in the chart below give the April report for the three clinics of the State Division of Mental Hygiene which are held in Boston. These clinics, which served 721 patients, were largely for children.

NUMBER OF ACTIVE CASES OF PSYCHIATRIC AND GUIDANCE CLINICS

April, 1936

Clinics	Total	Services		
		Full	Special	Other
Totals	221	536	135	50*
Habit Clinic	1-1	121	0	0
Judge Baker Guidance Center	96	179	72	45
Massachusetts Division of Mental Hygiene	150	132	18	0
Massachusetts General Hospital Psychiatric Clinic	154	104	45	5

*Includes diagnosis of other cases.

The details of hospital services are as follows:

HOSPITAL SERVICES

Twenty-one Boston hospitals and dispensaries supported by private funds reported to the Hospital Council that 19,591 patients were given 250,495 days care during the first three months of 1936. During the same period 213,537 visits were made to the

out patient clinics According to the information which was available for 228,469 days' care, the figures show that 77,837 days or 34.1 per cent were free and 150,632 days or 65.9 per cent were paid for. It is interesting to note that in the case of six hospitals, over half the days' care given was free, while for

two others the figure was just under fifty per cent. However, since it is highly probable that different methods were used by the individual institutions in computing these figures, they should only be accepted as an estimate of the amount of free service which is being rendered.

CORRESPONDENCE

RELIEF OF IRRITATION CAUSED BY MERCURIN
SUPPOSITORIES

June 11, 1936
Editor, *New England Journal of Medicine*,

The article, "Mercurin Suppositories as a Diuretic in the Treatment of Edema," by Dr. Marshall N. Fulton, in the *Journal* of May 28, 1936, prompts me to add the following simple, yet practical and effective suggestion:

My observations on the use of mercurin suppositories during the past three months correspond with those of Dr. Fulton except that my patients complained bitterly of severe burning, irritation and tenesmus of the rectum, until I coated the suppositories with nupercal ointment, an anesthetic salve. There was practically complete elimination

of the local discomfort, and no perceptible loss in diuretic action.

Sincerely yours,
390 Main Street,
Worcester, Mass.
EDWARD BUDNITZ, M.D.

RECENT DEATHS

RICE—ROBERT ASTLEY RICE, M.D., aged sixty-one years, residing at 21 Mechanic Street, Fitchburg, died Saturday, June 13, following a long illness which had incapacitated him since October, 1934. At the time of his death he was acting city physician and school physician.

Dr. Rice was born in Fitchburg, August 13, 1875, the son of the late Dr. Charles H. Rice and Della (Estabrook) Rice. He graduated from the Fitchburg high school in 1894, from Amherst College in 1898 and the Harvard Medical School in 1902. He immediately began the practice of his profession in

this city and joined the Massachusetts Medical Society in 1903. He was elected president of the Worcester North District Medical Society in 1933.

Dr. Rice assumed the practice of his father who died in 1917 after having practiced medicine in Fitchburg for more than fifty years. The young man inherited the quiet personality of his father and soon acquired a large clientele which he retained until his final illness. He was a World War veteran receiving his commission in October 1918 serving at Camp Greenleaf and at Staten Island, N. Y. and was honorably discharged November 19, 1919. He then affiliated himself with the National Guard retiring in January 1935 with the rank of lieutenant-colonel.

Dr. Rice was very prominent in the organization of the Northern Worcester County Public Health Association. A camp was established for the care of undernourished children and the good work originated by Dr. Rice is still being continued. He was for a time associated with the Burbank Hospital on both the medical and surgical services. These positions he resigned in order to devote more time to his private practice.

Dr. Rice is survived by his widow Mrs. Mary E. Rice and five children: Mark F. Murray, A. Helen, Joan, Robert A. and T. W. Peter, the eldest eighteen and the youngest ten years of age. A sister Mrs. Holland W. Wemple of New York City is also a survivor. The funeral was held from the Rollstone Congregational Church in Fitchburg on Tuesday June 16.

HURLEY—EDWARD DANIEL HURLEY, M.D., of 17 Willow Street, Belmont, died at the Carney Hospital, South Boston, June 8, 1936.

Dr. Hurley was born in 1881 and graduated from the Harvard University Medical School in 1904.

He was a Fellow of the Massachusetts Medical Society, the American Medical Association and belonged to the American College of Surgeons and other national medical organizations.

Dr. Hurley practiced medicine many years before becoming an eye specialist. He was a member of the staff of the Carney Hospital.

His widow Mrs. Isabelle Walsh Hurley, a daughter Miss Dorothy Hurley and three sons, Edward Jr., a student at Harvard, Paul and Vincent Hurley survive him.

BUMP—LEWIS NYD BEAR, M.D., of 124 Sycamore Street, Somerville, Massachusetts, died June 8, 1936. Dr. Bump was born in 1868 and graduated from the Albany Medical College in 1893.

His widow Mrs. Rosina (Holloway) Bump and two daughters survive him.

NOTICE

REMOVAL

HENRY ARTHUR KORTY, M.D., announces the removal of his office to 479 Beacon Street, Boston. Telephone Kenmore 8000.

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

The Harvard Medical Society met March 10, 1936 at the Peter Bent Brigham Hospital, with Dr. Walter B. Cannon presiding. The medical case was presented by Dr. Charles B. Altmeyer. A forty-two year old woman entered the hospital eighteen days previously complaining of pain in her right thigh of five days duration. The pain was of sudden onset, and had been "sharp" at first but had gradually become of a dull aching character. Physical examination was negative except for the findings of bilateral varicose veins, varicose eczema over both thighs and a hot reddened swelling over the course of the right long saphenous vein. Her past history was irrelevant, except for the vague story of recurrent attacks of bloody diarrhea which had once been diagnosed as ulcerative colitis. Laboratory studies showed a red cell count of 3,600,000, a hemoglobin of 70 per cent, a white cell count of 11,000 and a slight trace of albumin in the urine. Dr. Elliott C. Cutler, in commenting on the case, remarked that in this patient the right instead of the left leg was involved, which was contrary to what might be expected from an anatomical knowledge of the venous drainage of the lower extremities. The question as to whether thrombophlebitis might better be treated by ligation of the long saphenous vein was raised. The fact that emboli almost invariably arise from the deep venous system and not from the varicose superficial veins, shows that ligation is not indicated in such cases. Dr. John Homans stated that many cases of thrombophlebitis could be successfully treated by bandaging the leg and allowing patients to continue their usual activities. Patients so treated often recover from their illness in one-third the time required by those who are treated with bed rest. If the process is very acute with marked elevation of temperature, ambulatory treatment cannot be employed.

Dr. Richard L. Peterson presented the surgical case. A twenty-one year old Italian male entered the hospital twelve days previously with the complaint of a swelling of the left leg of two years duration. This swelling began on the lateral aspect of the thigh but soon spread to involve the whole leg from toe to groin. There was no history of epidermophytosis or lymphangitis. His past history was essentially negative. Three months before his entry to the Brigham Hospital a gonorrheal operation had been performed on his left leg at another hospital, without relief of his symptoms. Physical examination was negative except for the swelling of the left leg which was one-third larger than the right and a thickening and pitting edema of the skin of the whole leg. There was slight keloid formation in the scars of the previous operation. Four days previously he had been submitted to a retroperitoneal exploration of the pelvis. In an attempt to determine the presence of lymphatic occlusion the lymphatics draining the left leg were found to be

Attempts to carry out the rigid rest treatment in the patient's home were abandoned after a few failures. The patient must be quiet in mind as well as body. Most of the patients were treated in the New England Baptist Hospital. There they spent much time on the balcony where they could watch the sky and the changing scene. The rest was made as absolute as possible during the first part of the treatment. The Kareil diet consisting of 200 cc of milk four times a day without other food or fluid, has been used as a part of the treatment for about twenty years. It is given for four or five days and then other articles of food slowly added. Every effort was made to prevent depression or rebellion against the treatment. Especial care was taken to select cheerful efficient nurses. The removal from home to hospital, the strict rest, and the limited diet make adequate mental adjustment difficult. As an aid, by reducing sensibility to discomfort, morphine, panopon or codeine are given for several days. Under this régime, improvement was prompt. Attacks at rest rapidly diminished. One patient had an attack requiring nitroglycerine nearly every hour for the first twenty-four hours in the hospital. At the end of two weeks he was having only one or two attacks daily. In the five years that have passed since leaving the hospital he has never had an attack at rest. A patient with severe angina treated by nearly three months' bed rest in 1913 was seen in 1930. He stated that he had had no angina for years. Proger has shown by physiological studies that the Kareil diet reduces the work of the heart. Recently in a patient the effect of a rapid reduction in weight was tried without restricting exercise. It was found that the attacks of angina became less frequent and less severe.

The final paper of the evening was by Dr S H Proger on "Some Effects of Dietary Restriction on the Circulation With Preliminary Observations on the Role of Water Metabolism." Rigid dietary restriction such as to effect a loss of about 10 per cent of body weight, exclusive of edema fluid, over a period of two to four weeks has been shown to have beneficial effects on the state of the circulation in patients with heart failure. Some of the more important of these effects are slowing of the heart rate, lowering of the blood pressure and cardiac output, diminution in the size of the heart, lowering of the basal metabolic rate, increase of the vital capacity and decrease of the respiratory minute volume. The beneficial effects have been shown to persist so long as the lower weight level is maintained. There is a disappearance of the effects with a regaining of weight. However, when heart failure has been overcome and circulatory balance is re-established, extreme restrictive measures seem no longer necessary.

The beneficial effects above enumerated appear to develop to a more striking degree when weight loss occurs from a normal level than when the reduction is from an obese to a normal level.

In an attempt to determine the factors involved in the production of the changes described, a study is being made of the electrolyte balance during food restriction. Incidental to this study it was found that most of the changes hitherto associated with food restriction (notably a lowering of the basal metabolic rate) did not develop when care was taken to maintain the fluid intake during the period of food restriction at the same level as during the period of normal food intake. If, however, while food restriction was continued, the fluid intake was considerably reduced, the basal metabolic rate was distinctly lowered. The diet remaining unchanged this effect could be reversed simply by forcing fluid. It was then found that even on a diet of normal caloric content by "dry" so that the total fluid intake (including the fluid of the food) was only 900 cc, a lowering of 10 to 15 per cent of the basal metabolic rate could be obtained. This has led to further observations on the relationship of water to oxygen metabolism in patients who have abnormally low basal metabolic rates without clinical signs of hypothyroidism. In one such patient in whom the fluid intake and urine output were extremely low, forcing fluid produced a distinct elevation in basal metabolic rate (with however some clinical changes suggesting water intoxication despite the administration of normal saline solution). Further studies in this direction are in progress. The findings thus far indicate a definite and important relationship from the clinical standpoint between energy and water exchange in the manner above described.

OFFICERS OF THE NEW ENGLAND PHYSICAL THERAPY SOCIETY

At the recent annual meeting of the New England Physical Therapy Society the following named officers were elected: President, Dr Claude L Payzant, Vice Presidents, Dr George B Carr and Dr Chester S Leach, Secretary, Dr William D McFee, Treasurer, Dr Franklin P Lowry, Councilors, Dr John L O Toole and Dr Charles W McClure.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, JUNE 22, 1936

Wednesday, June 24—

112 M Clinic-Pathological Conference Children's Hospital

Thursday, June 25—

*8 30-9 30 A M Clinic, Surgical Staff of the Peter Bent Brigham Hospital, at the Peter Bent Brigham Hospital

Saturday, June 27—

*10 A M - 12 M Staff Rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A Christlan

*Open to the medical profession
†Open to Fellows of the Massachusetts Medical Society

June 21-23—Maine Medical Association at Bangor, Maine

June 22 and 23—The Medical Library Association. See page 1078 issue of May 21

June 29 July 11—Hospital Administration See page 957 issue of May 7

August 24—Harvard University Tercentenary Celebration See page 1168 issue of June 4

September 1936—First International Congress of Sanatoria and Private Nursing Homes See page 803 issue of April 16

September 7 10—International Union against Tuberculosis. See page 534 issue of March 1

September 14 and 15—Tercentenary Session of the Harvard Medical School See page 1166 issue of June 4

September 29 October 3—First International Conference on Fever Therapy See page 133 issue of December 26 1935 and page 1078 issue of May 21.

October 12 18—Third International Congress on Malaria See page 1016 issue of May 1

October 19 23—Clinical Congress of the American College of Surgeons. See page 180 issue of January 3

October 19 31—1938 Graduate Fortnight of the New York Academy of Medicine See page 11 issue of June 11

October 20 23—The American Public Health Association See page 126 issue of June 11.

April 21 24, 1927—American Society for Experimental Pathology See page 1078 issue of May 1

BOOK REVIEWS

Surgery Queen of the Arts, and Other Papers and Addresses. Willem D Haggard 339 pp Philadelphia and London W B Saunders Company \$5.60

The Medical World old and young would have been deprived of a scientific and intellectual treat had not Dr Haggard been persuaded by his many medical friends to gather together and publish in one volume this fascinating collection of medical addresses and essays. Dr Haggard has the rare gift of writing and speaking delightfully. Whether he is presenting a biographical sketch of some worthy medico conducting a clinic or reporting a series of surgical cases we read with pleasure and learn with ease.

In this volume we are not confounded by a wealth of statistics nor are we burdened by prolonged discussions. The light, charming literary touch is ever present to carry us along and add to our pleasure whether we choose to read the "Romance of Medicine" for pure delight or "Sarcoma of the Stomach" to improve our surgical minds.

The book is a collection of selected reprints written by a master surgeon and a charming personality. It is full of wisdom and experience on many surgical problems and in addition contains many delightful essays and biographies on fundamental medical practice and personalities of the Great who have passed on. The volume will appeal especially to the young surgeon and can well be an inspiration to him to broaden his future life and learn from a great master the too seldom acquired art of presenting surgical problems in a clear delightful and readable literary style. As Dr William J Mayo says in his Foreword, "There is an inspirational value in these notable addresses threads of the spirit and the humanities gleam through their fabric."

Child Psychiatry Leo Kanner Associate Professor of Psychiatry The Johns Hopkins University 577 pp Springfield and Baltimore Charles C Thomas \$6.00

As Professor Edwards A. Park of Baltimore writes in his preface to Child Psychiatry "This book of Dr Kanner's points out to the pediatrician the personal difficulties of children. It gives him the knowledge of their structure and intrinsic and extrinsic relationships and shows him how to investigate and analyze them. It supplies a point of view a method a way of thinking. It also furnishes the principles of treatment and therefore a way of acting."

No book, however comprehensive however logical and however lucid in construction can give to the untrained physician the ability or the time to practice psychiatry. The pediatrician may however gain a knowledge of personality development and the problems of behavior which will lead him to a better understanding of the psychobiological reactions of his patients and the ability to treat them in some instances, in his office.

A classification in the light of our present knowledge of children's personality disorders is a huge task and Kanner with the wealth of material of the Phipps Clinic to draw on is eminently fitted to undertake it. If the vocabulary frequently makes slow going for the nonpsychiatric reader it is because psychiatry has a terminology of its own with which the less enlightened student has relatively little familiarity. If treatment at times seems inadequately stressed it is because the treatment itself is inadequate. We must remember that a new field is being opened up one in which great advances have been made but in which greater progress still is to be expected.

It is no discredit to the book that the invisible hand of Adolf Mayer occasionally guides the pen of the writer for who in psychiatry could have a better guide or a greater teacher? There is by no means any hint at plagiarism in this statement, for all sources of material are scrupulously acknowledged. Particularly in the early sections of the work, its excellence is somewhat marred by poor proof reading. It improves steadily both in style and in interest as it progresses.

Great Doctors of the Nineteenth Century Sir William Hale-White 332 pp London Edward Arnold & Co 1935

The author a distinguished retired physician long connected with Guy's Hospital in London has taken advantage of his leisure to pass many pleasant hours in associating with the great doctors who have preceded him during the nineteenth century. He has moreover seen fit to put into print a series of delightful essays on seventeen physicians already outstanding in their time. Much of the material will be found in previously published books and yet Sir William has been able to give a new reading in a most delightful manner to the biographies of these men. The reviewer has again lived through the epoch of Edward Jenner Sir Astley Cooper Richard Bright Sir James Paget Lord Lister and the other noted Englishmen who have left their

mark on medicine around the world. Although there are many books of this type available to students and physicians, the reviewer knows of none so worthy as this one.

Traité de Thérapeutique A. Théohari. Tomes I and II. 1307 pp. Paris: Masson et Cie. 125 fr.

A detracting feature of many of our texts on pharmacology and therapeutics is that they are, as a rule, a treatise on pharmacology only. So far as therapeutics is concerned, they contain relatively little of any value. The more recently accepted forms of therapy, arrived at through clinical experimentation and experience, must be sought elsewhere in works on internal medicine, the various specialties and therapeutics per se. The present work is an excellent example of the last. It conveys in a concise and comprehensive manner Professor Théohari's accomplishments and teachings in this particular field. For example, each system of the body is considered in logical sequence, the diseases peculiar or attributable to it are treated in accordance with their particular etiology and symptomatology. Their therapeutics is described in minute detail. The pharmacology and action of the various medicaments employed, are elaborated upon. The text is excellently printed and very readable, which with the features described, make the volumes a ready source of reference. They are highly recommended to the internist, the general practitioner and the medical student.

Clinical Miscellany. The Mary Imogene Bassett Hospital, Cooperstown, New York. Francis F. Harrison, Charles C. McCoy, et al. Volume II. 1935. 218 pp. Springfield and Baltimore: Charles C. Thomas. \$3.00.

This volume consists of a collection of studies by the group of physicians of the Mary Imogene Bassett Hospital. Its objective is the correlation of the scientific medicine of the laboratory with the clinical medicine of the bedside. In total effect it is much like a volume of the Clinics of North America but includes both surgical and medical topics, the majority being medical. The subjects are of diversified practical interest and are ably discussed.

Fundamentals of Biochemistry in Relation to Human Physiology. T. R. Parsons. Fifth Edition. 453 pp. Baltimore: William Wood & Company. \$3.00.

For over a decade this small volume has been known to premedical students as one of the best-arranged introductions to biochemistry. Despite the incorporation of much information that was unknown when the first edition appeared, it still remains a handy textbook of basic facts. Indeed, the small size of the book—it goes readily into an overcoat pocket—betrays its usefulness. There are over four hundred pages of clear type, with many excellent diagrams and formulae. At the end of each chapter

there is an up-to-date bibliography. Its thirty-page index is surprisingly complete.

Progress in biochemistry has made such rapid strides since the World War that the practitioner's chemical training of those days is in many respects antiquated. This small book is written in clear and concise style. In it are many quite recent discoveries—among them the chemistry of the sex hormones. There is a chapter on "the human machine: its fuel requirements and energy output," which discusses metabolic requirements in relation to various foodstuffs. The chemical background of diabetes mellitus is summarized in another chapter. Still another discusses the pigments of the body, especially hemoglobin and its derivatives. In short, this book would make a very useful addition to the busy practitioner's library, because (as the caption heading the chapter on enzymes and oxidation catalysts says) "a little leaven leaveneth the whole lump."

Behavior Development in Infants: A Survey of the Literature on Prenatal and Postnatal Activity 1920-1934. Evelyn Dewey. 321 pp. New York: Columbia University Press. \$3.50.

Behavior Development in Infants by Evelyn Dewey is a very complete and well-organized summary of the experiments and observations on the first year of life. It presents the information now available in clear concise form. These data can be readily supplemented through the carefully selected bibliography. The book should be useful to the pediatrician as well as the psychologist and is a valuable addition to any reference library on child development.

Reports on Chronic Rheumatic Diseases: Annual Report of the British Committee on Chronic Rheumatic Diseases. Number One. Edited by C. W. Buckley. 159 pp. New York: The Macmillan Company. \$4.00.

This is the annual report of the British Committee on Chronic Rheumatic Disease, and represents primarily the British point of view of arthritis or rheumatism. It corresponds to the American report published in the *Annals of Internal Medicine*, April, May and June 1935, by Hench and his associates entitled *The Present Status of the Problem of "Rheumatism"*. A Review of Recent American and English Literature on "Rheumatism" and Arthritis. It is a book that the man interested in arthritic studies may find valuable to have on his bookshelves to be used as an Index Medicus. As a research symposium and compilation of a year's work on arthritis it leaves one rather confused, as all such compilations must do. The book explains the origin and development of the committee sponsoring its publication, and reports at length on classification and nomenclature. It includes original articles on allergy, hepatic efficiency, biochemical investigations, focal sepsis and the place of histamine in relation to chronic rheumatic diseases, on "ankylosing spon-

dylitis and chronic arthritis in children and critical commentaries on pathological orthopedic and surgical aspects on the trend of research in 1934 on nervous manifestations in chronic vertebral rheumatism, and on the possible relation between chronic arthritis and the function of the thyroid and parathyroid glands. Finally it includes a very incomplete list of the literature of the year. In comparison with the American report it seems to the reviewer definitely less comprehensive and less valuable to the general practitioner. There appears to be a tendency toward acceptance but not proof of bacteriological factors in arthritis. Both American and British reports show that there is weakness in the lines of research to date as demonstrated by the bibliographies published. To the reviewer's mind there are two flagrant omissions in such research programs. First, there is no mention made of the importance, in fact of the necessity of clinical follow-up study of the same group of arthritic patients over a long period of time. If accurate data along any line of study are to be secured. Conclusions based on figures culled from groups of patients shifting each year cannot actually be of great value. Few publications cite follow-up of more than two or three years. Most of them deal in months rather than years when speaking of improvement derived from one or another form of treatment. Secondly, in neither report is there mention of psychotherapy or of the possibility of psychogenic etiology of non-specific chronic arthritis. Until these two fields are covered by students of the arthritic problem as thoroughly as are some of the others, especially bacteriology, the reviewer prophesies a stalemate in its solution.

Das Ventrikulogramm I Teil Röntgentechnik Erik Lysholm 74 pp Stockholm P. A. Norstedt & Söner Swed. cr 10 —net.

This book is a very careful account of the technique used in taking ventriculograms at the Röntgen Institute in Stockholm. The type of machinery used, the normal and pathological appearance of the ventricles and the various positions in which the patient is placed are clearly illustrated both by a series of fine pictures and adequate descriptions in the text. There is appended a brief review of the literature on ventriculograms. This is the first part of a study of the whole subject and deals practically entirely with the technique. It is presumed that a later volume will deal with interpretation. The work already presented is of the highest calibre and one looks forward to future contributions from this Institute with pleasant anticipation.

Short Wave Therapy and General Electro-Therapy Heinrich F. Wolf. 96 pp New York Modern Medical Press \$2.50

This is a treatise devoted chiefly to short wave therapy but also including some technique on diathermy. Brief mention is made of low voltage

frequency currents, electrodiagnosis, static electricity, ultraviolet radiation, minor electrotherapy, electrodesiccation and electrocoagulation. The book is profusely illustrated with seventy-nine sketches showing the method and technique of applying electrodes to various parts of the body. The indications and contraindications for therapy are given as well as the average doses. There is a chapter on electrotherapy in otolaryngology by Farrel Jourd, M.D., and a chapter on electrotherapeutic procedures in gynecology by Edward Horowitz, M.D. The text is restricted to a minimum consistent with clarity. The book has been written especially for the general practitioner and the technician.

The Diagnosis and Treatment of Variations in Blood Pressure and Nephritis. Herman O. Moseenthal 616 pp New York Oxford University Press \$9.00

Dr Moseenthal's book takes up two distinct subjects, namely blood pressure and that part of renal disease which is loosely spoken of as Bright's disease. In general the volume explains both subjects clearly and in detail. There is perhaps a tendency to repetition but if this may be considered a fault it nevertheless adds to the clearness of the presentation. He takes up in detail the various methods of measuring blood pressure and after discussing what should be considered normal, describes the variations from normal. He emphasizes the importance of considering the pressure in capillaries and veins. One of the most instructive chapters is that one which shatters some of the theories about the effects of certain habits, food and drinks upon blood pressure. In that part of the book upon Bright's disease it is especially pleasing to find so much attention paid to the pathology of the kidneys. In recent years the tendency has been to discuss nephritis chiefly from the point of view of symptoms and physical signs and ignore the lesions in the kidneys. Moseenthal has revived interest in the pathological anatomy and might have gone even farther in including the physical signs with the structural changes in the kidney. It seems unfortunate that the term *nephrosclerosis* which the pathologists use extensively and which is used in this book is omitted from the index. A closer cooperation between pathologists and clinicians is important in Bright's disease. This book discusses the problems of diet in Bright's disease in a clear and simple manner. At the end of each chapter is a comprehensive bibliography.

The Parathyroids in Health and in Disease David H. Shelling. 336 pp St. Louis The C. V. Mosby Company \$5.00

In this book the author presents in review form the vast literature together with his own experiments on the physiology of the parathyroid glands. It represents an able summary by a man who has spent considerable time thinking over the problems of this field who has himself made contribu-

tions in the laboratory. It is to be regretted that the author's limited clinical experience with the disease of hyperparathyroidism should make the clinical part of the book of little value. There are such obvious omissions and errors in his discussion of the clinical picture of overactivity of the parathyroid glands that this book cannot be recommended to the practitioner seeking knowledge to guide him with clinical problems. The book, however, will be read with interest by physicians and laboratory workers who are already conversant with this field of medicine. By them his extensive chapter bibliographies will be found most useful.

The Human Foot, Its Evolution, Physiology and Functional Disorders Dudley J Morton 244 pp
New York Columbia University Press \$3 00

Dr Morton, Associate Professor of Anatomy at Columbia University College of Physicians and Surgeons, has written a very complete, interesting, and entertaining monograph on the human foot, which ably reflects his long standing interest and careful research on the foot and its problems.

He devotes the first part of his book to a discussion of the evolution of the foot, tracing its development from the amphibian to man. Particularly interesting are the chapters on proanthropoid and anthropoid changes, and the terrestrial modifications of gorilla and early prehuman feet. These comparative anatomical studies are the result of much investigation and a wealth of anthropological material. Finally, the human foot itself is considered, and the bony and muscular factors in its development discussed.

The second part of the book is devoted to the physiology of the human foot. The importance of the relation between the centre of body weight and foot function is stressed, and the relative importance between structural and postural stability discussed. Contrary to general orthopedic teaching, Dr Morton minimized the importance of muscle balance. The mechanics of the foot in walking and running are taken up, and the gaits of apes, African savages, and civilized peoples compared.

The third and final section of the book considers functional disorders of the human foot. Details of physical examination are discussed with particular emphasis on x-ray examination and interpretation. The graphic method used by Dr Morton in recording and studying gait is extremely ingenious and appears to be a great advance over the clumsy and complicated methods used heretofore. Dr Morton concludes that the chief primary factors in producing functional disturbances in the foot are the following: shortness of the first metatarsal or, what amounts to the same thing, posteriorly placed sesamoids; hypermobility of the first metatarsal segment; short calf muscles. Methods of treating these clinical factors are given which are new and logical, and it is to be hoped that at some later date Dr Morton will supplement his excellent

book with a clinical end result study of cases diagnosed and treated according to the principles he has formulated.

Agents of Disease and Host Resistance Including the Principles of Immunology, Bacteriology, Mycology, Protozoology, Parasitology and Virus Diseases. Frederick P Gay 1581 pp Springfield and Baltimore Charles C Thomas \$10 00

This volume contains 1581 pages. It presents by the different associates of Frederick P Gay practically all of the present day branches of medicine relating to disease agents, whether inanimate or animate. The reviewer has turned to this book as a reference work fifteen times since he received it for review, each time finding successfully, and in brief, concise form, the information he was seeking. It is more than a textbook presentation, it is a reference book for the average man of medicine. The data given are accurate, complete, and well presented. An outline of the parts into which the book is divided will indicate the material included.

Part I General Aspects of the Causation, Classification and Nature of Disease

Part II Inanimate Disease Agents and Tolerance.

Part III Living Disease Agents, particularly Bacteria, Their Morphology and Physiology

Part IV Infection and Epidemiology

Part V Resistance and Immunity

Part VI Pathogenic Bacteria and Diseases Produced by Them

Part VII Pathogenic Spirochetes and Spirochetoses

Part VIII Pathogenic Fungi and Fungus Diseases

Part IX Indeterminate Pathogenic Forms and Diseases Produced by Them

Part X Animal Pathogens

Part XI Diseases of Obscure Etiology

Part XII Practical Results in the Diagnosis, Prevention and Cure of Infectious Diseases

This book is recommended to the medical profession as a book which will be used constantly, in order to obtain information necessary in the daily demands of a general practice.

Laboratory Methods of the United States Army Fourth Edition Edited by James Stevens Simmons and Cleon J Gentzkow 1091 pp Philadelphia Lea & Febiger \$6 50

The fourth edition of this most useful laboratory manual, edited by Dr James S Simmons with Dr Cleon J Gentzkow as Associate Editor, shows a number of important additions. Recognition is made of the increasing importance of statistics in medical work by including an excellent, though brief, section on statistical methods. A brief outline of the method of testing various foods and beverages is given. A useful summary of various toxicological procedures is also presented. The manual, comprehensive in ground covered, simply yet adequately written, will be of great service to any practitioner.

er doing a moderate amount of laboratory work or called upon to do an occasional test. This outgrowth of Medical War Manual No. 6 has kept pace with the development of medical knowledge since the World War and yet has avoided reaching a cumbersome size.

La Thymus Anatomie — Histologie — Physiologie Clinique et Thérapeutique G. Worms et H. Pierre Klotz. 152 pp. Paris: Masson et Cie. 30 fr.

This monograph covering the anatomy, pathology and physiology of the thymus represents a clear and concise presentation of the French attitude toward this organ. The material from the French literature is adequately covered. The volume however will be chiefly of supplemental interest to American readers, omitting as it does discussions of the more recent hormone work particularly that centering about Hanson's extract. The consideration of status thymico-lymphaticus is very sane and practical and should serve to weight down more heavily the tumbrel of this discredited but all too frequently resurrected hypothesis. The illustrations are well chosen and technically satisfactory.

You Must Eat Meat. Fables, Follies and Facts About Meat. Max Ernest Juttie. 164 pp. New York: G. P. Putnam's Sons. \$2.00.

This small book describes the digestive and circulatory systems and indigestion with special reference to auto-intoxication and the development of chronic diseases, in simple terms. It also gives an account of the "New Dietetics," the follies and facts of meat consumption, and the effects of meat as compared with carbohydrate ingestion in the human body. And it ends with favorable comments on the use of the Salisbury Diet in health and in the treatment of chronic diseases. The book is written largely for lay readers.

The Diseases of the Endocrine Glands Hermann Zondek. Third Edition. Translated by Carl Prausnitz. 492 pp. Baltimore: William Wood & Company. \$11.00.

One is constantly asked where it is possible to find a good résumé of the present status of the endocrine glands with special emphasis on the clinical aspects. The answer is that such a résumé does not and probably cannot exist. Any such attempt in rapidly advancing a field where so much is being written must by the nature of things suffer almost on publication from the criticism of being out of date and inaccurate. Furthermore, since many of the problems are still controversial any exposition which attempts to be didactic and complete is bound to meet with the disapproval of those readers who have their own viewpoints on these questions.

And yet in spite of these objections such works do fill a need in one's reference library and are

better than nothing. The three German textbooks on Clinical Endocrinology (Zondek, Bauer, Falta) all very much alike contain a lot of valuable information and this new translation of Zondek's with revisions by Carl Prausnitz is a welcome addition. The chapters on the physiology of the glands cover many of the more recent advances.

The Special Procedures in Diagnosis and Treatment. An Outline for Their Understanding and Performance Don Carlos Hines. 66 pp. Stanford University. Stanford University Press. \$1.00.

This sixty-six page outline presents the salient points about such familiar hospital procedures as gastric lavage, oxygen therapy and blood transfusion. In addition to describing the apparatus and technique of its use it summarizes the indications, contraindications and complications. At the end of each chapter is a list of references for more complete study. This book will find its greatest usefulness in the hands of the medical student or nurse who is about to commence work with hospital patients for the first time.

The Modern Treatment of Burns and Scalds Philip H. Mitchner. 64 pp. Baltimore: William Wood & Company. \$2.00.

Nearly three-quarters of this booklet of sixty pages is devoted to a consideration of the tannic acid treatment of burns both by the spray and compress methods. The applicability of the latter method seems overemphasized. It is the opinion of many surgeons that the method is efficient and convenient for ambulatory burns but that either immersion or the spray method with drying and exposure to the air is preferable for extensive burns. The preservation of tannic acid in solution, powder and tablet form is discussed. The rest of the volume is devoted to a terse presentation of the treatment of special burns.

As a ready reference book, the volume may fill a need in the first-aid room of industrial plants.

The Diagnosis and Treatment of Disorders of Metabolism James S. McLester. 3.8 pp. New York: Oxford University Press. \$5.00.

With the rapidly accumulating knowledge the disorders of metabolism are assuming a unitary position in the field of medicine. The author proceeds from a discussion of normal metabolism to that of intermediary metabolism, water balance, acid base equilibrium, gout, obesity and diabetes mellitus. Although valuable as bringing together in a single volume a discussion of these conditions, most of what appears in this book can be found in modern textbooks on clinical medicine and applied physiology. Furthermore, in a volume designed chiefly for the practicing physician, the many pages devoted to complicated laboratory technique such as the Van Slyke plasma bicarbonate determinations (fifteen pages) as a single example certainly run counter

to its purpose. The pages allocated to these laboratory procedures could be more profitably utilized. The recently developed subject of the metabolic disorders resulting from the parathyroids is omitted.

The reviewer feels that there is a place for such a volume but extensive revision is necessary.

The Patient and the Weather William F Petersen
Volume I Part I 127 pp Ann Arbor Edwards
Brothers, Inc \$3.75

This is one of a series of monographs on the same subject. Some of the later volumes, such as the one on nervous and mental conditions in relation to the weather, have preceded this introductory section and have been reviewed, as they appeared, in *The New England Journal of Medicine*. With this volume, a certain confusion about the nature of the project is now cleared up and the author's purpose made more evident.

The main thesis concerns the effect of the environment on the patient, chiefly the immediate environment, namely, the weather and the season. While admitting that there are many other environmental factors influencing the individual, such as emotions, diet, intoxications, infections and fatigue, these are difficult to evaluate. The weather, however, can be measured with considerable accuracy, is an important factor and, moreover, has been thoroughly ignored in modern medical teaching and medical practice.

The field covered is a wide one. Both the normal person and the patients are considered as influenced by meteorological conditions. Maps and pictures are freely used in an endeavor to show why some people are able and some dull, "why Vermont produces more genius but also more insanity, why individuals die of tetanus and paresis in a clear cut track right across the country, while to the north and to the south the death rate falls," and similar topics. Many of the figures are based on the statistics supplied by the United States Draft material and the Census of 1930. Various diseases are noted with maps showing their frequency in various states.

How much can be added to our knowledge by investigations of this kind is an open question. Because of the author's obscure style, his easy assumption of premises not held by all scientific workers, and his tendency to moralize, the work is difficult to evaluate. If the value is there, it is obscured by a mist of indistinctness.

The Stomach and Duodenum George B Eusterman, Donald C Balfour, and others 958 pp
Philadelphia and London W B Saunders Company \$10.00

This book, from one of the most famous clinics in America by two well known men, covers from the medical as well as the surgical side the diagnosis and treatment of diseases of the stomach and duodenum. Each phase of a patient's disease from

its beginning to the follow up treatment is carefully given. Case histories are detailed, methods of examination explained, laboratory findings discussed, all admirably. Diagnoses, preoperative care, detailed operative or medical treatment are interestingly covered.

From the surgical standpoint, every operation is given in full with the step by step technical drawings. The photographs and drawings are so fine that they make the procedures clear.

From a medical standpoint, treatment is fully discussed and exact details are given. Even diets as compiled by the St. Mary's Hospital dietitian can be found fully stated in the appendix.

Chapter 59 with its discussion of late sequelae of surgical treatment is particularly unique.

This book cannot fail to appeal to both internists and surgeons, for it is the most complete, detailed and up-to-date single volume yet published on the diseases of the stomach and duodenum. It should be of permanent interest to the general surgeon and general practitioner and invaluable to the specialist in gastroenterology.

A Practical Handbook of Midwifery and Gynaecology for Students and Practitioners W F T Haultain and Clifford Kennedy Second Edition 356 pp
Baltimore William Wood & Company \$5.25

This book is written in the manner of a quiz compend, and it attempts to cover the field of obstetrics and a part of gynecology. Some of the subjects are summarized satisfactorily, others are not. Its only value would be to students making a hurried review of a subject, but it is so at variance with teaching in this country that it would be of little or no value here in America.

Tumors of the Urinary Bladder Edwin Beer 166 pp
Baltimore William Wood & Company \$3.50

From the experience gained in his clinic at the Mt Sinai Hospital in the past twenty five years, Beer has reached the sound and clear-cut conclusions expressed in his book. Some six hundred and fifty cases of bladder neoplasm form the basis for his observations. In presenting his facts and the conclusions arrived at from a study thereof, the author has shown the best of judgment in that he gives us all the important points and does not make his text top-heavy with statistics and minor details. By reading this book of one hundred and thirty pages one can get a clear idea, in good perspective, of the pathology, symptomatology and treatment of bladder tumors.

Beer, who was the first to suggest the use of the high frequency current for the transurethral destruction of vesical papillomas, limits this method to tumors which appear to be benign or at most are in the class of papillary carcinoma of low malignancy. He sometimes implants a few seeds of radon about the bases of these tumors provided there is no evidence of infiltration of the base.

For more extensive growths his experience leads him to prefer resection of the entire thickness of the bladder wall even if this involves reimplantation of the ureter to radium. Incidentally the results which he obtained by reimplantation of the ureter in forty-three cases were satisfactory enough to teach us that this is a feasible procedure.

Beer has been an advocate of total cystectomy in selected cases. Nreterostomy has been his method of diverting the urinary stream. While his results with this method have been distinctly better than the results of most surgeons employing ureteroenterostomy it is not at all certain that this solution will be the final one. Improvements in the technique of nreteroenterostomy may so reduce the mortality from this operation that even with its added risk and multiple operations it will prove to be the more satisfactory procedure.

In Beer's experience deep x-ray therapy has accomplished little except the control of hemorrhage but he suggests that further developments in this method may increase its efficiency. He believes that some patients with multiple rapidly recurring tumors of low malignancy have been benefited by x-ray treatment.

This monograph can be recommended as a clear and sane statement of the present status of the management of a disease which is too often treated in an illogical half-hearted way. Beer's attitude is one of radicalism tempered with sound judgment.

The Diagnosis and Treatment of Diseases of the Heart. Henry A. Christian. 373 pp. New York: Oxford University Press. \$6.00.

This book is a reprint of the volume originally issued in loose-leaf form in 1928 as one of the monographs of the Oxford System of Medicine. It has been brought up-to-date as can be seen by its inclusion of such subjects as the use of mercupurin and a discussion of the merits of total thyroidectomy for heart disease. It is divided into sixteen chapters describing the diagnosis and treatment of acute endocarditis, myocarditis and pericarditis and of chronic diseases of this nature: syphilis of the aorta, angina pectoris, cardiac infection, thyroid heart disease, arrhythmias, cardiac neuroses, congenital heart disease and the pharmacological action of digitalis.

While it is not a highly detailed discussion of the subject of cardiac disease it has been in a standard text for some years and written "primarily for practitioners of some considerable clinical experience. It can readily be seen to be the product of a very wise physician. Dr. Christian's views on some disputed points are well known, such as the value of digitalis as a daily ration in all adults in whom cardiac hypertrophy can be demonstrated, the belief that the higher degrees of the so-called "myxedema heart" are due to myxedematous pericardial effusion and not to dilatation of the heart, and his conservative attitude toward focal infection as a factor in cardiac disease.

A few minor omissions might be mentioned such as the recent work on the relief of attacks of auricular paroxysmal tachycardia by acetylcholine derivatives, the much larger series of patients with angina pectoris treated by paravertebral alcohol injection than is included and the rather striking evidence that congenital idiopathic hypertrophy of the heart is at least sometimes associated with abnormal deposits of glycogen in the muscle. It would seem unwise to recommend intravenous quinidine to the general practitioner without an added word of warning as to its danger and not all would agree with the author's feeling that alcoholic beverages are inimical to patients with angina pectoris. The use of the metric system is theoretically advisable in the prescription of drugs but it must be admitted that the practitioner will probably continue to figure digitalis doses in grains and not milligrams and perhaps both systems should be used throughout a book like this. For the sake of accuracy it should be noted that the titles of figures 15 and 16 have been partially transposed, the first figure actually showing the position of the mitral valves and the second the aortic.

All physicians in general practice are forced to have an interest in heart disease and this volume is an excellent one on which to rely. It is to be recommended not only to them but to those whose primary work is concerned with cardiac problems.

Modern Treatment in General Practice. Volume II. Edited by Cecil P. G. Wakeley. 352 pp. Baltimore: William Wood & Company. \$4.00.

The second volume of this series which evidently has met with cordial reception in England is a broad survey of recent trends of medicine covering a large number of subjects in a concise and practical manner. The names of the authors can but demand respect, and they have reduced their material to useful and accessible form. Forty miscellaneous topics from gastric ulcer to fracture of the femur are discussed in the three hundred pages. The aim of the writers has been to make this a work to which a busy man could turn and find specific information that would be immediately helpful. This is by no means the first book designed for this purpose but it differs in that the authors have filled the prescription. The sections are plently full of facts without theory and at the same time can be read with pleasure. The best articles are those dealing with fractures particularly the Thomas splint and its wide field of application.

Essentials of Psychopathology. George W. Henry. 312 pp. Baltimore: William Wood & Company. \$4.00.

This is a book based upon personal experience. As Professor Adolf Meyer says in the preface the author "takes the reader into his workshop and study with an opportunity to share the facts as found and the methods as used." The material is

strictly up-to-date and conforms to the best in the practice of psychiatry as now carried out in the leading clinics of the world. Due emphasis is laid upon the work of Freud, but the subject is handled in a manner much broader than a strictly Freudian point of view. A few case histories are added to the record, but most of the book consists in describing the way investigations are made of psychiatric problems, plus a summary of what justifiable conclusions can be drawn about the most complicated part of medicine. In modern psychiatry there is a wealth of existing material with almost endless interpenetrations. To cull from this mass an important contribution to the subject limited to three hundred pages is the task set by the author. He has succeeded perhaps better than anyone before him and this book should find a place in the library of all interested in mental disease.

Über die Rhythmik der Leberfunktion, des Stoffwechsels und des Schlafes Erik Forsgren 56 pp
Göteborg N J Gumperts Bokhandel

This protocol contains the results of studies of the daily changes in the liver, gallbladder the secretion of urine, the body temperature and metabolism. The investigations were carried out during sleep in addition to during the waking hours. As a result of twenty-four hour examinations both histological and biochemical, of the liver cells, their glycogen content, the amounts of bile secretion, the variations in the size, color, consistency and taste of the liver itself, the author believes that its function is rhythmic in character.

He also states that the metabolic changes constantly occurring in the body are rhythmic, even during sleep. This study should be of interest primarily to the physiologist and the student of physiology.

A Treatise on Medical Jurisprudence Benton S Oppenheimer 290 pp Baltimore William Wood & Company \$4.00

This handbook is not to be confused with a treatise on legal medicine concerning itself with the various conditions where medical science is invoked to solve problems coming before a court of law,—but is designed primarily “to assist members of the medical profession in determining what legal rights and obligations arise out of the relation of physician and patient.” The author is a lawyer of wide experience in these matters, and writes in a style both lucid and as free as possible from technical verbiage. The ground covered includes a review of the laws regulating licensure, the legal aspects of the relation of physician and patient, malpractice and actions brought in its name, the nature of rules of evidence, dying declarations, a physician's right to compensation, compulsory medical or surgical treatment, and the right to perform autopsies. The sections on expert testimony, with the author's critical

but friendly comments on the physician as an expert witness, and on privileged communications, should be read and gratefully apprehended by the physician before he goes on the witness stand. The book as a whole is warmly recommended to all physicians, as well as to lawyers who presumably will find its numerous citations invaluable.

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles Edited by Louis Hamman Volume 4 forty-fifth series 1935 331 pp Philadelphia, Montreal and London J B Lippincott Company

In this volume we find a group of articles of diverse nature. There is an excellent balance between the practical and theoretical aspects and because of the thoroughness of the reviews, we are offered the quintessence of recent advances in knowledge.

Regional Anatomy Adapted to Dissection J C Hayner 687 pp Baltimore William Wood & Company \$6.00

This volume presents the unfamiliar aspect of a textbook of anatomy without illustrations. It does not aim to be a general, systematic anatomy, a surgical anatomy, a dissection manual, or an atlas, but rather to present the subject matter of regional anatomy in brief but inclusive and strictly descriptive form. The BNA terminology is employed throughout with occasional bracketed references to vernacular or traditional nomenclature. Fifty-one selected regions are thus described in 635 pages, avoiding on the one hand the brevity of the compendium and on the other the diffuseness of the larger standard treatises. As a means of review in preparation for examination or for a proposed surgical operation, the book deserves much praise. It is obviously not a textbook for the beginner, but should fill a definite place in the library of the surgical practitioner.

Pathologie Digestive P Harvier 162 pp Paris Masson et Cie 22 fr

This is a short volume published under the direction of Dr A Sezary. Professor Harvier has stressed the physiology and pathologic anatomy associated with digestive disorders. It is well written. Although not complete in any sense of the word, it amply covers the salient points of intestinal and gastric diseases.

Gynecological and Obstetrical Tuberculosis Edwin M Jameson 256 pp Philadelphia Lea & Febiger \$3.50

This is an accurately titled, scholarly textbook for reference and study, not for leisurely reading. Under each of over a hundred headings the literature of the world is reviewed and appraised. For this a list of over a thousand references is appended.

Though written by a young man who has been in practice less than ten years it gives just consideration to conflicting views and sound conclusions from his own cases almost all of which were apparently complicated by severe pulmonary lesions.

There is a particularly thorough discussion of routes of infection with concise description of experimental work done apparently in Saranac. The author shows commendable skepticism about any possible diagnostic link between menstrual deviations and pelvic tuberculosis. He shows brave frankness in recognizing the poor prognosis in conservatively treated tuberculous salpingitis and oophoritis but appreciates also the rare justification for such treatment. He evinces encouraging optimism regarding small doses of x ray (five more or less each of 50 R units more or less) for special cases of intrapelvic genital tuberculosis in which radical surgery is inadvisable for instance for the very young who want to remain intact and those with severe complicating pulmonary lesions. The use of radium he deprecates.

The discussion of pregnancy and tuberculosis is fulsome and wholesome. With enviable insight he has derogated what he calls "polemic literature" but considers wisely the many reports of the dependable experience of good clinicians. Again and again he emphasizes the necessity for adequate care of tuberculosis during pregnancy and the puerperium which he insists is almost impossible to obtain with the present setup of sanatoria and maternities. Regarding prevention or interruption of pregnancy this well-informed discreet obstetrician and phthisiologist takes no absolute stand. He states in detail all the conflicting attitudes but shows clearly that each case is to be considered on its own manifold conditions.

So "meaty" and "digestible" is this book, the reviewer is tempted to abstract it rather than criticize it. It is well worth the careful study of all who practice medicine for tuberculosis in women is common. It will prove invaluable to all who specialize in obstetrics or gynecology or phthisiology.

This young author has written an excellent book. He should go far for he will be of great value to medicine. The publishers too have presented his work in excellent style. It is a tidy little volume with pleasing paper and good print.

High Blood Pressure and Its Common Sequelae
Hugh O. Gnewardene 123 pp. Baltimore: William Wood & Company \$3.00

This book written in Ceylon has very little to recommend it to the American reader. Most of the information contained in its pages was common knowledge in this country ten years or more ago. Many of its chapters are very loosely written and many of its references are frequently given without regard to whether the accepted standards. Case reports with insufficient data to make them interesting are

sprinkled throughout the pages with far too little comment.

One chapter however has considerable human and some scientific interest to the American reader. This deals with the blood pressure in three groups of sedentary individuals: the Buddhist priests, the Moslems and the Chetties and one group—the rickshamen whose occupation involves extraordinary physical exertion. By contrast to the ricksha runners whose pressures tend toward low normal, the pressures in the other groups whose activities are chiefly mental range slightly above normal.

For and Against Doctors. Robert Hutchison and G. M. Wainchope. 168 pp. Baltimore: William Wood & Company \$2.00

Charles L. Dana was evidently right in his remark that "all the real solid elemental facts against doctors were uttered some one or two thousand years ago." Hutchison and Wainchope have collected a small volume of medical satire, extravagant praise and dispraise from the literature of the ages. A source of useful quotations for occasional use. It makes a delightful addition to that class of books for both doctors and patients that can be picked up on the run and opened to any page.

Appareil Circulatoire. Ch. Lauthy. 186 pp. Paris: Masson et Cie. 22 fr.

This short compendium on the circulatory system is one of a series published under the direction of Dr. A. Sézary. It is a small volume of 186 pages and envisages the recent methods employed in the diagnosis of cardiac disease.

The book is intended for students and is not a comprehensive work on the subject.

Röntgenology. The Borderlands of the Normal and Early Pathological in the Skiagram. Alban Köhler. Second English Edition revised by the Author. 681 pp. Baltimore: William Wood & Company \$14.00

This is the second edition of the English translation of Köhler's work which has long been known as the Roentgenologist's Bible. To roentgenologists it is probably the most valuable single book in the English language.

The present edition has several improvements over the first. It is better printed, contains over one hundred additional pages and the illustrations have been supplemented with captions which add definitely to its value as a book of reference.

As the title suggests the field covered is the borderland between the normal and pathological—a field which offers many puzzling problems. It is a book which every roentgenologist should have and use.

The True Physician The Modern "Doctor of the Old School" Wingate M Johnson 157 pp New York The Macmillan Company \$1.75

A Modern Doctor of the Old School is the appropriate subtitle of this sane and realistic presentation of the art of medicine. A book that should be on the shelf of every recent medical graduate, it will be a safe guide and friendly counselor for many years. The author is obviously a man of thoughtful experience, a man who has seen life with clear vision, who, while sufficiently idealistic, never soars into the clouds of saccharine platitudes that characterize most works of this kind. In the hundred and fifty pages he covers the rights, ideals, duties, compensation and conduct of the physician, under practically all conditions, his reading, social life and many-sided relations to a fickle and demanding public. In easy simple language a valuable message is conveyed.

One cannot escape the certainty that Wingate M Johnson, the author, has loved his work, that he is a man one would be proud to call "my doctor."

Synopsis of Clinical Laboratory Methods W E Bray 324 pp St Louis The C V Mosby Company \$3.75

In contrast to many laboratory manuals, this little book is not only relatively brief but proves to be a mine of information. Written in the form of a synopsis rather than as a textbook, and containing a minimum number of illustrations, it will prove to be a handy and valuable reference compendium for the laboratory. As far as the illustrations are concerned, the line drawings and colored illustrations are reproduced well, but the photomicrographs often lack clearness. The author has restrained himself to technique and has not attempted to make an interpretation of laboratory tests, but on page 103 he states "It is not within the scope of this synopsis of clinical laboratory methods to discuss the differential diagnosis of the various blood diseases. Brief mention, however, will be made of them," and then follow three pages of clinical notes on the various blood dyscrasias, many of which are inaccurate and often misinforming. It is suggested that in future editions, clinical discussion be omitted. Aside from this minor fault, this little volume cannot be too highly recommended.

The Diagnosis and Treatment of Diseases of the Peripheral Arteries Saul S Samuels 260 pp New York Oxford University Press \$3.50

This rather nice looking, small volume on a subject of such live interest is somewhat of a disappointment. The reviewer feels that the author does not do himself justice. He obviously knows thrombo-angiitis obliterans to which subject he has devoted 190 of 254 pages. It is difficult, however, to understand the paragraph in the preface, reading as follows:

"This study is based on the examination and treatment of over 350 cases of thrombo-angiitis obliterans and of a larger number of cases of peripheral arteriosclerosis, during the past ten years. These cases were seen both in private practice and in my clinics for peripheral arterial diseases at Bellevue Hospital and the Stuyvesant Polyclinic. Of the 350 cases of thrombo-angiitis obliterans, only one required amputation because of complete destruction of the foot by the gangrenous process, due to superimposed arteriosclerosis."

It is incredible to men who have studied this disease with considerable care and detail that 350 consecutive cases of thrombo-angiitis obliterans could possibly have been followed through to the termination of their disease with only one major amputation.

The rather sarcastic vein which the author takes as regards the opinion of other authors on the subject and the types of treatment that have been helpful in other clinics, but of which he does not approve, makes for an unfortunate impression. The treatment that the author seems to feel most effective is that of repeated intravenous injections of hypertonic salt solution, which has not been found to be a specific by other investigators.

The author deserves a great deal of credit for his conservative ideas and rarely can such ideas be carried to an extreme when dealing with this disease.

A Synopsis of Physiology A Rendie Short and C I Ham Second Edition Edited by C L G Pratt 312 pp Baltimore William Wood & Company \$3.50

In the second edition of this work Dr Pratt has kept the structure of the original and has brought the outlines of general physiology up-to-date. The new additions include the latest work on vitamins, sexual physiology and endocrinology.

One is truly amazed at the amount of knowledge that has been packed into this small volume, and yet despite its condensed nature the material is unusually interesting and cohesive because of the excellent sequential arrangement. Enough of anatomy is included for understanding of the text and whenever a point has clinical bearing it is mentioned. A third of the space is devoted to the physiology of the nervous system and special senses. There is an excellent index but no bibliography.

The authors do not intend this work to serve as a textbook in physiology but rather as a summary to be used by the student in his review and by the clinician in bringing his knowledge up to date. For both of these purposes it is admirably suited.

Thérapeutique Hydro-Climatologique des Maladies du Foie et des Voies Biliaires. Paul Carnot, Maurice Villaret, et René Cachera 152 pp Paris Masson et Cie 20 fr

This short volume is of no value, and offers no new material in the treatment of liver and biliary diseases.

NUMBER 26

THROMBO ANGIITIS OBLITERANS WITH SPECIAL REFERENCE TO ITS ABDOMINAL MANIFESTATIONS*

BY SIDNEY SLATER COHEN, M.D.† AND MAURICE E. BARRON, M.D.†

SINCE the establishment of thrombo-angitis obliterans as a clinical and pathological entity in 1908¹ the disease has been regarded until recent years as one involving only the vessels of the extremities and more especially the lower. That such a restriction is artificial and erroneous has become the growing impression of many observers who have been of the opinion that the disease is widespread in its distribution. It is our aim to help to clarify and establish this impression as fact and particularly to define the abdominal manifestations of the disease as a surgical entity.

Buerger was the first to discuss the possible general aspects of the disease, stating that little was known regarding the participation of arteries other than those of the extremities in the characteristic process. He quoted four cases of the disease involving systems distant from the original proved thrombo-angitis of the extremities, and found coronary arteriosclerosis in one, thrombo-angitis of the coronaries in another and central arteriosclerosis with bland thrombosis in two, to account for the clinical picture. Barron and Lantieri² in 1929 called attention to "the more general distribution of the disease in contradistinction to what has previously been believed concerning it—that it is a disease involving the blood vessels of the extremities exclusively. They believed that it attacked the walls of the vessels throughout the entire vascular system—giving signs and symptoms characteristic of the regional vessels and organs involved. A study of thirty-four cases was made (twenty-seven of their own, seven in the literature) in which, with thrombo-angitis of the extremities (only a few proved histologically, the rest typical clinically) episodes suggesting involvement of cerebral, coronary and other vessels occurred. In view of the young age group in these cases, with years of disease prior to definite nutritional disturbance, it was felt that thrombo-angitis was here a general disease with involvement in these distant loci and that arteriosclerosis, when present, was superimposed. However, in this group only four autopsies are

quoted these showing changes suggestive of the disease. This is a very small proportion.

Brown and Henderson,³ LeMann,⁴ Lewis,⁵ Tanbe,⁶ Allen and Wilkins,⁷ Riesman,⁸ and McGregor and Simson⁹ all quote cases of thrombo-angitis obliterans with cerebral, coronary and other episodes suggestive of extension of the primary process but again with no post mortem material. Livingston¹⁰ quotes such a case and remarks on the frequency with which patients, who have had a "stroke" or coronary attack, complain of intermittent claudication and night cramps of the legs. He states "I feel that the clinical entity we have been calling Buerger's disease is not an entity at all, that there probably are a variety of causes functional and pathological, for an obliterating arterial disease process which may attack the terminal arborizations of arteries anywhere in the body."

Jäger¹¹ in an extremely thorough and diligent treatise on the subject, has detailed the histopathology of the disease in its various stages and concludes similarly.

It would seem however as though histopathological proof of the widespread nature of the disease were sadly lacking in the literature, that more autopsy material was highly essential for enlightenment. Buerger has stressed this, and the preponderance of purely presumptive case reports has borne out the contention.

This paucity of autopsies is probably due to a number of factors: first to the chronic nature of the disease leading itself to numerous hospital admissions with eventual self restriction to home care and exitus away from the hospital, secondly, to the temporary arrest of the disease often by amputation leading to eventual exitus from cause other than thrombo-angitis obliterans—again outside of hospital, thirdly to the orthodox Jew's aversion to postmortem examination.

LeMann quotes but six autopsies on thrombo-angitis obliterans in the literature through 1928: four of them Buerger's (as above) one Perl's and one LeMann's. Sprunt¹² in a recent article on "generalized thrombo-angitis obliterans," found eighteen cases the above included in the literature with autopsy. All of these showed some lesions of the visceral arteries in many cases simply arteriosclerosis in others a

From the Department of Surgery, Beth Israel Hospital, Boston, Mass.

*Cohen, Sidney Slater—Junior A. Lect. Surgeon, Beth Israel Hospital, and Member of the Vascular Clinic, Beth Israel Hospital. Barron, Maurice E.—Assistant Professor of Surgery, Tufts College Medical School. For record and addresses of authors see "This Week's Issue," page 122.

smaller group, purely thrombo-angitic, and in a third group, mixed types. Sprunt presents a careful analysis of the site of involvement, age, duration of symptoms with other vital statistics, revealing as a whole that there exists in these cases a general vascular disease, terminating in most cases with the usual vascular accidents one associates with arteriosclerosis and hypertension.

Aveibuck and Silbert,²⁹ in a very thorough treatise on the cause of death in thrombo-angitis obliterans, were able to detail the histopathological background in a large series of cases. Of forty-five cases of proved thrombo-angitis obliterans of the extremities who died, twelve or 21 per cent died of intercurrent non-vascular disease, twenty-two or 41 per cent succumbed to visceral vascular accidents, the remainder of asthenia and operative intervention. Of these forty-five, nineteen came to autopsy, three of them Buerger's cases. Of these, only one case presented distant lesions typical of thrombo-angitis obliterans as in the extremities, while eleven or 58 per cent had occlusive, non-typical visceral processes. The association between thrombo-angitis obliterans in the extremities and visceral accidents as manifested in this and other series certainly cannot be an accidental one. Undoubtedly the incidence is much greater than in a group of normal individuals. One cannot help but define in thrombo-angitis obliterans, as Silbert points out so aptly, a "constitutional inferiority of the entire vascular system with abnormal thrombotic tendencies and early degenerative vascular changes with local variations, making for a variable clinical and histopathological picture."

Search of the entire literature to date reveals that there are to be but a handful of autopsy reports on thrombo-angitis obliterans. Those, with our own, we detail in the accompanying chart—unfolding and correlating the clinical and histopathological aspects of the disease. In the records of the Beth Israel Hospital, we have had from August, 1928 to May, 1934 seventy-seven admissions of thrombo-angitis obliterans. Of this number, four died and all came to autopsy. These we include in Chart 1.

It will be seen then that, of thirty-nine available autopsy reports there were vascular lesions distant from the original disease in the extremities in thirty-seven, of which group, seven showed histopathologic change characteristic of thrombo-angitis obliterans, and four showed questionably pathognomonic lesions—while in the majority the pathologic process was not characteristic of thrombo-angitis obliterans, but in most cases, of arteriosclerosis.

Buerger likewise noted that such material as had been collected had failed to define changes entirely characteristic of the disease in these

distant places. He felt that great care was necessary in interpreting the significance of the endarterial lesions found at necropsy, especially in the distant place, since intercurrent affections, atherosclerosis and secondary thromboses, with such changes as healing might induce, could play a rôle in producing the final histopathological picture, not at all typical of the disease. He points out that arterial channels affected by thrombo-angitis are inherently disposed to atherosclerotic changes as well as proved by study of autopsy material and amputated limbs. Study of the latter, especially at secondary or re-amputations, may disclose, only a few months after the first operation, marked atherosclerotic change not present earlier, and displacing the typical lesions of thrombo-angitis obliterans found previously.

Graves, in a concise account of the histopathology of the disease, points out that in thrombo-angitis, when the lesion has existed for many years, a secondary thickening of the intima takes place with corresponding proliferation of elastic fibres that must not be confused with the arteriosclerotic process. The latter, however, he states, is often associated with thrombo-angitis and one finds atherosclerotic plaques in which the elastic fibres are arranged more or less parallel with the internal elastic lamina, encroaching on the lumen. Evidently, in these cases, a predisposition to vascular disease manifests itself both in a susceptibility to thrombotic lesions as well as to degenerative ones.

Autopsy findings—according to Graves and others—also show that in thrombo-angitis obliterans the more centrally situated arteries develop a tendency to arteriosclerotic lesions even though the arteries of the extremities show but little sclerosis. One may thus find arteriosclerosis, thrombo-angitis, or both in these centrally located vessels. The histopathologic differentiation of thrombo-angitis obliterans and arteriosclerosis in the extremities rests on the involvement of nerves and veins and the relatively spared internal elastic layers in the artery, typical of the former process. In the other organs of the body one usually encounters the non-specific thrombosis typical of many types of occlusive vascular disease.

Thus one is left with the impression that even with definite thrombo-angitis of centrally located vessels, the usual chronic course with recurrent inflammation and superimposed arteriosclerosis leads to a histological picture at eventual examination uncharacteristic of thrombo-angitis obliterans. One is forced therefore to define these distant areas of thrombo-angitic involvement purely on an empirical basis, the clinical story, the concomitant process elsewhere comparative youth for arteriosclerosis and the localization of the process, rather than the histopathological picture.

With these thoughts in mind the clinician should be better able to interpret vascular phenomena complicating any type of peripheral vascular disease and particularly thrombo-angitis obliterans. Coronary and cerebral episodes we understand as such. Occlusion of vessels in other viscera often goes unnoticed or is left unrelated to a generalized arterial disease process. Spasm, inflammation, vessel wall change, collateral circulation all play a role in the interpretation of the clinical syndrome of thrombo-angitis obliterans and must be so emphasized.

Led to unusual interest in the subject of generalized thrombo-angitis obliterans by reason of previous work on the subject by one of us—and because of the extraordinary case we will present—it became our task to investigate the abdominal manifestations of the disease. As the literature was investigated it became evident that there are extremely few cases of proved involvement by thrombo-angitis of intra-abdominal vessels and only a few suggestive cases. We were also led to realize that there was a new entity to be considered in the differential diagnosis of the acute surgical abdomen.

The cases in Chart 2 as detailed constitute all those found in the literature indicating proved or presumptive involvement by the disease of intra-abdominal vessels.

Investigation of the literature thus disclosed only fifteen cases suggesting involvement by thrombo-angitis obliterans of blood vessels of the alimentary tract, a remarkably small group. Of these, only four are proved, two others doubtfully proved and the remainder (nine) presumptive. There are doubtless encountered clinically hundreds of cases of thrombo-angitis obliterans of the extremities in which temporary fleeting abdominal episodes occur—probably due to either acute thrombo-angitis of the vessels or spasm, or both. This Lewis Conner⁷ recently stressed, suggesting that our knowledge of the events following thrombosis of coronary or cerebral vessels be applied to the problem of recognizing visceral vascular occlusion.

The prognosis in these cases depends upon the delicate balance between gross occlusion, collateral circulation and spasm. Failure to maintain this balance manifests itself by the ischemic pain seen in occlusive involvement of coronary, extremity or visceral arteries. Failure to recognize this possibility and the deplorable lack of autopsy findings have helped to keep uncertain and obscure our understanding of the general nature of the disease. We feel that these cases, as well as ours, constitute a definite indication that thrombo-angitis obliterans of the intra-abdominal vessels is a well-established step in the progress of the disease, and must be taken into consideration in the differential diagnosis of the acute surgical abdomen.

The clinical picture is usually one of partial

intestinal obstruction, colicky abdominal pain, vomiting, obstipation or diarrhea, distention and fever. Similarly, the comparatively early age group the presence elsewhere in the body of thrombo-angitis obliterans and the absence of arteriosclerosis elsewhere lead one to feel that the basis for all these cases may best be ascribed to generalized thrombo-angitis obliterans with abdominal manifestations. Why the vessels of the extremities are more frequently involved than others is not known. It is possible that to greater vascular demands, to static conditions and to exposure of the vessels to mechanical and thermal irritations we may ascribe the more frequent involvement of the peripheral vessels. It is our hope that the above cases and ours to follow, may bear out the contention that, though less commonly occurring and less recognized, thrombo-angitis obliterans of intra-abdominal vessels is a definite clinical entity.

The following case is offered as an interesting, but unfortunately only presumptive case of abdominal *Buerger's disease*—

S. A., thirty-four year old single Russian Jewish tailor entered Beth Israel Hospital February 10, 1931 with coldness, blueness and crampy pain in the arch, sole and big toe of the right foot of twenty-nine months duration and in the sole and lastph of left foot, of fourteen months duration made worse on walking and with cold. At that time, physical examination revealed phlebitis migrans of the right leg and thigh and left foot both feet especially the right, were cold and blue. Femoral palpations were both good but popliteals, posterior tibials and dorsalis pedis bilaterally absent.

Posterior tibial nerve block with skin temperature readings revealed no vasospastic element in his disease. On March 26, 1931 right popliteal vein ligation with biopsy of artery was done. The latter found completely fibrosed. Pathologic diagnosis: arterial thrombosis with cannalization. On February 6, 1933 for migrating phlebitis a left saphenous vein ligation was done. Biopsy revealed acute and subacute inflammation typical of thrombo-angitis obliterans; this was confirmed by re-examination of earlier biopsy specimens (Figs 1 and 2.)

Typhoid vaccine intravenous saline ultraviolet light exercises restricted activity were all tried but made little impression on the development of subsequent events.

Admitted May 23, 1934 with colicky periumbilical pain of thirty-six hours duration with vomiting, obstipation, prostration. Two months previously he had had his only previous attack, being prostrated in bed for one week with recurrent attacks of low abdominal midline cramping pain with vomiting and diarrhea. Physical examination now revealed an undernourished man, toxic, with dry tongue, scaphoid abdomen with slight motion on respiration, extreme tenderness and spasticity of the entire right side of the abdomen—most marked opposite the umbilicus. The temperature was 100.5 F., rectally pulse 114, respiration 28 and WBC 26,000. Examinations showed findings as at previous examinations. Immediate laparotomy was done with the preoperative diagnosis of probable acute appendicitis and a secondary diagnosis of thrombo-angitis obliterans of the mesenteric vessels. There was disclosed patchy gangrene of the hepatic flexure of the colon involving one and a half foci of the length of the bowel mostly on the antimesenteric

border. Spots of necrosis were thin and varied in size from $\frac{1}{2}$ to 2 centimeters in diameter with normal bowel in between. No thickening of bowel or of mesentery was noted. The pulsations of the mesenteric vessels were definite up to an inch from the bowel margin, where in this particular locality

of the lesion and the abdomen closed. The convalescence was stormy. On the eighth day there developed a frank fecal fistula which gradually diminished in size until his discharge on the twenty-third postoperative day.

FIG 1

Acute Stage of Thrombo-Angitis Obliterans. Note the infiltration of all layers of the vessel by leukocytes, the lumen filled with clot in the periphery of which there are millary giant cell foci.

FIG 2

High Power View of One of Giant Cell Foci Noted at Rim of Thrombus in Previous Slide. Note typical leukocytic infiltration of all vessel layers.

they were not palpable. There was fibrin over the serosa of the colon and small bowel, thereby tying them together. Disrupted to expose the pathology. It was felt that there was a good chance of regression of the process and, accordingly, nothing further was done. Drains were placed to either side

FIG 3

X-ray taken after the First Operation. Note inflammatory hepatic stricture with dilatation of cecum and ascending colon proximal to presumptive thrombo angitic involvement of bowel vessels.

FIG 4

X-ray taken after the Second Operation. Note stricture and ileo transverse-colostomy. Note dilatation of cecum and ascending colon.

On July 9 1934 barium enema revealed a marked constriction at the hepatic flexure (operative site) 35 centimeters long and 25 centimeter in diameter (Fig. 3). There was no delay or obstruction and clinically no pain or distention. Defecation occurred twice daily and the stools were soft, semi formed guaiac negative. The possibility of neoplasm of hepatic colon was considered though inflammatory stricture was felt to be the probable underlying pathology.

There ensued gradual distention some cramps which with the x-ray picture led on August 21 1934 to ileo-transverse-colostomy for inflammatory stricture and partial intestinal obstruction. At this time the surgeon found the left common iliac artery to be thickened fibrosed with faint pulsations and several areas of calcified plaques. At the same time all the sensory nerves to the right foot were crushed except for the sural nerve that his toe might tolerate more vigorous local treatment.

The convalescence was uneventful except for some abdominal distention with parumbilical cramps. A checkup on Sept. 14 1934 revealed marked distention of the proximal half of the colon which was regular in outline except for the previously noted defect at the hepatic flexure. The ileo-transverse colostomy stoma was one half inch in width and barium flowed through this stoma into the ileum and also by the stoma into the proximal colon. (Fig. 4)

We have thus a thirty-five year old man with a six year background of proved thrombo-angitis obliterans of the extremities who six months and again four months previously had had an acute gastro-intestinal episode. At operation spotty gangrene of hepatic flexure was found with poor pulsations in the vessels near the bowel margin and thickening and fibrosis of the left common iliac artery but no other palpable changes. Drainage of the abdomen was followed in turn by fecal fistula inflammatory stricture and ileo-transverse-colostomy for progressing obstruction. There then loomed the possibility of the development of blind loop pathology that might have necessitated resection of the right colon and terminal ileum.

It is the presumption that thrombo-angitis obliterans of the mesenteric vessels was the fundamental basis for the intra-abdominal process. Proof of this may be forthcoming at resection of his vessels at some future date. In light of our knowledge of pathological changes in chronic thrombo-angitis obliterans we realize that we may find no typical lesions. This man may go on to further similar attacks he may manifest cerebral or coronary changes attributable to his thrombo-angitis obliterans. His prognosis is questionable.

SUMMARY AND CONCLUSIONS

- 1 The literature on the autopsy material of thrombo-angitis obliterans is reviewed. Thirty nine available autopsy reports are abstracted.
- 2 Thrombo-angitis obliterans is a generalized disease process which may affect vessels anywhere in the body, giving a clinical syndrome dependent upon the vessels and organs affected.
- 3 In the chronic stage of the disease arteriosclerosis often accompanies, and may displace, the typical thrombo-angitic changes in the vessels involved. In such cases a presumptive diagnosis of thrombo-angitis obliterans can be based only on clinical evidence.
- 4 Suggestive abdominal signs and symptoms,

in a patient with thrombo-angitis obliterans of the extremities, may be due to involvement of the intra-abdominal vessels by the disease process. Recognition of this fact may modify the therapeutic approach and prognosis.

5 The literature on abdominal Buerger's disease" is reviewed. Fifteen available case reports are abstracted.

6 A presumptive case of "abdominal Buerger's disease" is presented.

NEW HAMPSHIRE MEDICAL SOCIETY

PROCEEDINGS OF THE
ONE HUNDRED AND FORTY-FIFTH ANNIVERSARYHouse of Delegates, Manchester, N H
May 25, 26 and 27, 1936

THE House of Delegates convened at the Hotel Carpenter Manchester, New Hampshire, on Monday evening May 25, 1936, at seven-thirty o'clock

Speaker James B Woodman presided

The Secretary called the roll and the following members responded

The President, ex officio
The Vice President, ex officio
The Secretary-Treasurer, ex-officio
Richard W Robinson, Laconia
Raymond J Turley, Meredith
William J Paul Dye, Wolfeboro
Francis J C Dube Center Ossipee
Osmon H Hubbard Keene
Frank M Dinsmoor, Keene
Richard E Wilder, Whitefield
Robert M Deming, Glenciff
Roland J Joyce, Nashua
Deering G Smith, Nashua
Clarence E Dunbar, Manchester
Charles H Cutler, Peterborough
Henry H Amsden, Concord
Warren H Butterfield, Concord
James B Woodman, Franklin Falls
Lawrence R Hazzard, Portsmouth
Harry O Chesley, Dover
Jeremiah J Morin, Rochester
Henry C Sanders, Jr, Claremont

PRESIDENT ABBOTT I appoint Dr Keeley to take Dr Moriarty's place, Dr George C Wilkins to take Dr Laiochelle's place, and Dr Frederic P Lord to take the place of Dr Sycamore

SPEAKER WOODMAN I appoint the following Committee on Credentials Dr Dinsmoor, Dr Deming and Dr Cutler

DR DINSMOOR There are nineteen delegates present with credentials

SPEAKER WOODMAN For the Committee on Communications and Memorials, I appoint Dr H H Amsden, Dr L R Hazzard and Dr R. W Robinson

For the Committee on Nominations, I appoint Dr Clarence E Dunbar, Dr Richard W Robinson and Dr Osmon H Hubbard, Dr Richard E Wilder and Dr Frederic P Lord

The next item of business is the report of our President, Dr Clifton S Abbott

Report of the President

It seems almost superfluous for me to address you at this time. The President usually says all he cares to say in his address before the So-

ciety. The reports of the Secretary and various committees will doubtless cover the ground thoroughly

I would recommend that the second session of the House of Delegates be held in the evening of the first day, as will be suggested by our Secretary

I would recommend that we hold our meetings on advanced time, if a majority of our cities have adopted it

We are confronted with the necessity of deciding whether we will accept Federal Aid as offered under the Social Securities Act for crippled children, connoting the broadest interpretation of the term, and for others that might be eligible under the Act. The people back of the movement are working through the State Board of Health. I am informed that they have a list of about two hundred children requiring some medical aid. If their plans do not meet our approval, we should have a program of our own to care for these people. My address of tomorrow is on this subject

One of the best accomplishments this year was the securing of the Postgraduate Fellowships offered by the Commonwealth Fund. This makes real postgraduate instruction possible to a limited number of members of this Society, offered in a very attractive form, the details of which are covered in the report of the Committee on Medical Education and Hospitals

The Committee on Cancer has been very active, and deserves commendation for its booklet on the early diagnosis and treatment of cancer. One member of your Committee is a member of the State Cancer Commission, which has established diagnostic clinics throughout the State, and conducted campaigns of cancer education last winter

The Committee on Maternity and Infancy has sent out literature that should be valuable to those doing this work

The Committee on Public Relations has had an easy year, but next year, the situation will be far different, with the legislature in session

We should elect one or two members from each county society to the State legislature in either branch. I have urged this at every county meeting that I have attended. I believe that it will be difficult to do this, for a man in active practice would have to make quite a financial sacrifice. If a doctor could be assured of not too great a financial loss, there would be no

difficulty in getting good men to run. As a constructive measure, I would suggest that the Society devise some means of caring for the physician's practice during his absence.

There is almost sure to be legislation pertaining to sickness insurance at the next session of the Legislature. There should be key men placed about the State who would make it their business to know the character and education of the candidates for public office. The Editor of the *Illinois Medical Journal* says, "Do a little research on these men doctor, before election."

There are too many suits for malpractice in the State. There will probably be a continuance of these suits. It would seem that the average doctor is an optimist never believing that he may be sued until trouble strikes him. The gospel of the Golden Rule and the power of organized co-operation should be preached.

There should be some measures devised to limit the number of men admitted to practice in the State for in this way only can the quality of medical practice be improved. The ratio of doctors in New Hampshire is one to seven hundred, which taking into consideration the wealth of the people is the saturation point.

The Society's work is less in infrequent meetings. The House of Delegates meets but once a year. I believe that there should be a session of the House with the various committees in the early winter each year that the General Court convenes.

SPEAKER WOODMAN: This report is referred to the Committee on Officers Reports.

The next item of business is the report of the Secretary Treasurer.

Report of Secretary Treasurer

To the Members of the House of Delegates of the New Hampshire Medical Society

The following report for the year 1935 is herewith submitted

Total Membership December 31 1935

PAID MEMBERSHIP

Belknap County	23
Carroll County	14
Cheshire County	27
Cook County	31

January 1, 1936 Balance in check book	1,011 68
	\$3,847 44

The Society has increased its membership slightly and is in sound financial condition. During 1935 the customary \$500 was not added to the Trust Funds but since the beginning of the present year, the Treasurer has turned over to the Trustees \$1,000. The Benevolence Fund now amounts to \$1,174 95. This fund has been increased during the past year not only by the routine allotment of fifty cents from the annual dues of each member but also by generous gifts from the Women's Auxiliary of several county societies.

One of our Councilors died during 1935. Abiam W Mitchell of Epping, a distinguished and widely known physician.

On Tuesday afternoon President Abbott will present a gold medal to a Manchester doctor who has been a member of this Society for fifty consecutive years. In one respect this presentation will be unusual because the doctor is a woman,—Ellen A Wallace. At the same time two physicians who have been in practice for fifty years will be duly honored. They are Frederick L Hawkins of Meredith and John F Robinson of Manchester. Dr Robinson cannot attend our meeting. He has been a helpless invalid for two years, his wife writes that Dr Robinson has spoken many times of this being the year he would receive special recognition from the Society for his long years of service. I would suggest that the House of Delegates write him an appropriate letter.

For the two appointive offices which he with in the province of your President, Dr Abbott has made the following choices. For Anniversary Chairman, Richard W Robinson of Lacombe and for a member of the New England Medical Council, Robert H Brooks of Claremont.

Recommendations which the House of Delegates made a year ago have, I believe, been carried out in their entirety. An edition of the booklet containing the revised Constitution and By-Laws has been printed and distributed. A notice has been sent to each member urging him to consider seriously becoming a candidate for

the General Court. To the joy of your President and Secretary, the Vice-President has undertaken some of the necessary and desirable visits to County Societies, he has also been enrolled as a member of the Committee on Public Relations.

To a certain extent the Council has ceased to lubeinate. The members have elected a Chairman, this year they are having the annual get-together which the By-Laws prescribe. Two or three times during the year a local Councilor has served judicially and expeditiously in straightening out some question of ethics or department pertaining to his particular county.

The Committee on Liability Insurance, which was disbanded a year ago, has been replaced by a new subcommittee of three selected from the membership of the Advisory Committee on Jurisprudence. Henry C Sanders, Jr of Claremont is Chairman of this new subcommittee on Liability Insurance and the other two members are David W Parker of Manchester and Arthur T Downing of Littleton.

The Committee on Medical Education and Hospitals has carried out the two tasks which were entrusted to it: the formation of a Speakers' Bureau and the establishment of Postgraduate Education.

For the Speakers' Bureau a most impressive group of New Hampshire doctors have signified their willingness to address any county society at any time. Their topics cover a wide range. It is to be hoped that harassed county secretaries who have difficulty in arranging their programs will patronize our new bureau liberally.

For members of this Society who desire postgraduate study, the Committee on Medical Education and Hospitals has arranged, through the Commonwealth Fund, for fellowships in medicine, pediatrics, obstetrics and office surgery at the Harvard Medical School. I need not dilate upon the generous offer from the Commonwealth Fund, you have all received a circular letter from the Committee describing the fellowships in detail.

Your Committee on Publication has attempted again during the past year, as you recommended, to brighten its particular corner in *The New England Journal of Medicine*. To this end, the Committee subscribed to one newspaper in each of the ten Counties in the State and clipped from these papers interesting items concerning doctors, hospitals and nurses. These items formed a column of miscellany which was published from time to time, as an appendage to the more serious medical and surgical papers inherited from the most recent annual meeting.

And speaking of the *Journal*, may I quote a paragraph from a letter which I recently received from its Editor:

"Several years ago the Massachusetts Medical Society arranged to publish the proceedings of your state society in monthly serial issues of *The New England Journal of Medicine* for which your society pays the *Journal* one dollar per year per member. It was agreed at that time to furnish all of the remaining forty issues for three additional dollars to be paid by those members who would like the complete volumes. Several of your fellow members have taken advantage of this arrangement but it has come to our attention that many do not know that, by paying three dollars this six-dollar *Journal* will be supplied for the full year."

How many members of our Society read any medical journal?

How many read *The New England Journal of Medicine*?

How many would be interested in this liberal offer? And, if there are any who would be interested how may the offer best be called to their attention?

And now for a few scattered facts about other committee work. The Advisory Committee on Jurisprudence met in Concord two or three times during 1935. On one occasion your President, your Secretary accompanied by your legal adviser, went to Lancaster to straighten out a tangle in the north country. In one case which the Committee considered—that against one of the hospitals in Nashua—a large verdict was awarded to the plaintiff. Otherwise from a medicolegal point of view we had little serious difficulty during the year.

The Committee on Scientific Work has made bold to eliminate tentatively from the program of the annual meeting for 1936 the address of welcome by the Mayor and the report by the Chairman of the Committee on Arrangements. The Committee on Scientific Work felt that the periods allotted to these two time honored speeches might better be spent in medical discussion, if the Committee is wrong in this supposition or if anyone's feelings are hurt it will be entirely feasible to revert another year to the "horse and buggy" formula.

This Committee would emphasize once more that it is badly in need of good papers which are read at county meetings by our own members or by visitors from other states. Some of the papers that you will hear tomorrow and on the following day have already been read at county meetings. Please keep this thought in the back of your heads and let the Secretary know when a good county paper comes along that is suitable for the wider audience of our annual gathering. Dr. Harris E. Powers of Manchester has agreed to serve as a liaison officer between the General Chairman of the local Committee on Arrangements and the Committee on Scientific Work in planning the annual meeting. The General Chairman changes every year and Dr. Powers, because his service is continuous, will be of great value in checking the innumerable details of our sessions.

Since our last meeting the Committee on Public Relations has had a vacation, due to the fact that our General Court has not met. A relative holiday also has been the lot of the Advisory Committee on Medical Relief. The rules and regulations which were formulated a year ago by this committee apparently met with fair success for several months but more recently because of lack of State funds these rules and regulations have been less effective. The situation is explained in a recent letter from the Acting Director of Relief which I quote

Since November 1 the state has not been reimbursing the counties, cities and towns for fifty per cent of their relief expenditures and the local subdivisions have been carrying the entire load.

"We are unable to answer your question as to whether the doctors throughout the state are getting paid for operations and medical calls by their respective county commissioners. We do know however that under the law payment of surgical and medical bills is a matter which will have to be decided by the respective boards of county commissioners.

"Under the present law the administration of relief rests wholly with the county city and town relief officials and all decisions as to its administration must be made by them.

The efforts of the Committee on Maternity and Infancy are epitomized in two or three circular letters which have been sent to all members of the Society. This Committee is disturbed because some of the maternal deaths seemed to them to be unnecessary. They will probably ask you, in their report, to advise them as to what action can or should be taken to remedy this dilemma. If they do not make this request, I make it herewith because the matter seems to me to be important.

Incidentally I have wondered why the Committee on Maternity and Infancy and the Advisory Committee on Medical Relief together with two other committees should be listed as Special Committees. I am at a loss also, to understand why the New England Medical Council and the newly appointed Committee on Medical Economics are Rotating Committees. Why should not these two Committees be formed on the same permanent bases as are their brethren?

To each County Society your Secretary has recently sent a letter which reads in part as follows:

I have recently conferred with representatives of the leading Accident Insurance Companies in New Hampshire regarding medical fees in compensation cases.

"These representatives tell me that the compensation law does not include any official fee table and that the charges made by doctors in different parts of the State vary a great deal. The Accident Companies would like to have a gentlemen's agreement with the members of the New Hampshire Medical Society whereby save in exceptional cases which require prolonged or unusual treatment the fees would be standardized.

There is, I understand, nothing binding in such an agreement. The agreement provides merely a working basis for the doctors and for the Insurance Companies.

"Please note particularly that this schedule applies only to WORKMEN'S COMPENSATION cases. It has nothing to do with automobile injuries and similar accidents to private individuals."

One fee table provides a lump sum for major surgery, the other provides a fee for initial treatment with regular charges for aftercare. Do you wish to take any definite action in this matter?

Your Secretary has conducted two investigations by postal card during the past year. The first postal card read "Do you wish the New Hampshire Legislature to appropriate funds to carry out the medical provisions of the Social Security Act which are outlined in the enclosed circular?"

The first postal card questions what action, if any, this Society should take concerning the medical features of the Social Security Act. The Federal Government will provide a certain amount of money if New Hampshire will provide a similar amount. Heretofore, New Hampshire has covered most of the suggested medical care on its own initiative without financial assistance from the Federal Government and the question arises whether it is desirable and necessary for the State at this time to undertake a much more elaborate service, under Federal supervision which would, of course, involve a considerable appropriation at the next Session of the General Court.

About one third of the members of the Medical Society returned the postal cards and this group voted four to one against the proposition. The medical features of this act are apparently constitutional. The matter has been turned over to the Committee on Medical Economics and they have been asked to report their conclusions to you at this meeting.

The second postal card read "Have you any suggestions for improving the scope of the details of the annual meeting which is to be held next May?" From the second postal card concerning the conduct of the annual meetings the following thoughts were born:

- 1 Start the sessions promptly
- 2 Have a marshal with a small megaphone to announce the beginning of the meetings and start the crowd in from the lobby
- 3 Have the microphone in order
- 4 Take better care of visiting delegates
- 5 Use the films shown by the College of Surgeons
- 6 Give the final speaker a larger audience
- 7 Emphasize the need of Liability Insurance
- 8 Have more New Hampshire papers
- 9 Have symposia on chronic arthritis, diabetes and endocrinology
- 10 Demonstrations of electrocardiography, obstetric operations (manikin), laboratory procedures
- 11 Have movies
- 12 Show photomicrographs on the screen

- 13 Have the Society purchase a lantern and a screen
- 14 Have a clinic at a local hospital
- 15 Have a skin clinic
- 16 Have no music at the banquet, in order that there may be an opportunity for fellowship and conversation
- 17 Have speakers at the banquet limited in number and also in time

The Committee on Scientific Work will be glad to have your advice on these questions. Which of them are wheat and which are chaff?

Your Secretary has his own suggestions for improving the annual meeting, namely, the adoption of the plan which, for the past three or four years, has been so effective in our neighboring state of Maine.

Among the minor details that prevail in Maine I would call your attention to the following:

1 The second meeting of the House of Delegates is held at five o'clock on the afternoon of the first day.

2 The introduction of visiting delegates and the presentation of fifty-year medals occur at the banquet. Incidentally visiting delegates attend the banquet without cost to themselves.

3 The presentation of the President-Elect is similarly deferred until the banquet.

More important than these details, however, is the arrangement of the Scientific Sessions. Each morning is utilized for a series of round-table conferences on a multiplicity of subjects conducted by the members of the Maine Medical Association. General sessions in the afternoon are devoted to papers by out-of-state guests.

In Maine, the morning conferences have become very elaborate. If our Society could procure suitable accommodations it seems to me that we might have a smaller number of conferences of this type which would yet be adequate to serve each member of the Society in attendance. It might be wise to repeat, at eleven o'clock in the morning, for a new group of members, the same conferences that had previously been given at nine-thirty o'clock. Each member would be expected to sign in advance for the particular conferences which he wished to attend and a definite limit would be set in each case on the number of men that could be accommodated.

CARLETON R. METCALF,
Secretary-Treasurer

SPEAKER WOODMAN: We will now hear from the Committee on Officers' Reports relative to the report of the Secretary-Treasurer.

DR. D. G. SMITH: On the report of the Secretary-Treasurer, we note particularly the strong financial position of the Society. We wish to commend him for the manner in which he has brought before the doctors of the Society, either

directly through circular letters or through the county societies, many of the problems that are confronting us.

We recommend that the Secretary write an appropriate letter to John F. Robinson of Manchester, who has been in the practice of medicine for fifty years, but who because of illness is unable to attend this annual meeting.

I move the adoption of that portion of the report.

This motion was duly seconded and carried.

DR D. G. SMITH. We believe that many of the members of the Society are unaware of the liberal offer that the Massachusetts Medical Society has made and that the Secretary in his next communication to the members should remind them that they can purchase for \$3.00 a year the remaining numbers of *The New England Journal of Medicine*.

I move the adoption of that part of the report.

This motion was duly seconded and carried.

DR D. G. SMITH. We believe that the establishment of even an unofficial fee schedule for workmen's compensation cases is inadvisable. We believe that the state fee schedule and the various county fee schedules should prevail. If, at some future time it would seem that such a fee schedule for workmen's compensation cases would be advisable, we recommend that this matter be investigated by the Committee on Medical Economics, which committee would report to the House of Delegates.

I move the adoption of that part of the report.

This motion was duly seconded.

SECRETARY METCALF. This schedule is the one in effect in Vermont passed two or three years ago by the Vermont Legislature.

SPEAKER WOODMAN. Dr. Abbott, what is your reaction to this subject?

DR. ABBOTT. I thought it wasn't a bad proposition.

DR D. G. SMITH. I should like to read part of a letter received from Dr. Leland of the American Medical Association.

He says, "You will note that there is a wide variation among the different States in these schedules."

"In most of the States these fee schedules have been prepared in co-operation with the medical societies and often with the participation of the Compensation Commissions and some of the employers, especially such of the latter as are self insurers. Developments in a number of states within

recent years would seem to indicate that insurance companies are beginning to realize the value of good medical service and the necessity for control of such service by the medical societies."

DR GEORGE C. WILKINS. I believe that it would be very much wiser to take some co-operative action with the insurance companies on this matter. This applies only to workmen's compensation and it seems to me this compensation to the medical profession as a whole is not a very large proportion of their compensation. I think that some sort of a conference ought to be arranged.

DR R. W. ROBINSON. I cannot see in glancing over the fee schedule as presented that it differs very much from our own state fee schedule at the present time.

DR. FRANK KITTRIDGE. This subject was brought up before the Hillsborough County Medical Society at a recent meeting, and they voted unanimously to turn it down. I do not believe that it is anything that should be settled tonight. A Committee should be appointed to study the subject and to take the matter up with the insurance companies. I do not believe it is anything that we should act upon hastily.

DR. CUTLER. I was present at the meeting about which Dr. Kittredge has spoken. The sentiment was very strongly against it but, like him, I feel that it should be given very careful consideration and I think that some members of our profession should meet with the insurance people and come to an adjustment of this matter.

DR. HAZZARD. If we have a State fee table I would suggest that that table be sent to every member of the Society, and then also sent to the insurance companies, as a basis for fees in compensation cases.

DR D. G. SMITH. As to the fee schedule of the New Hampshire Medical Society, the only one I was able to find was one adopted in 1924 which is for general practice only, and which takes up only the fundamentals of practice.

PRESIDENT ABBOTT. Wouldn't it be well to have a fee schedule prepared for the State? I know there is a great deal of difference in the fees charged in the different sections of the State.

DR D. G. SMITH. I withdraw my original motion.

I move that the matter of an unofficial schedule for workmen's compensation cases be investigated by the Committee on Medical Economics, which Committee shall report to the

House of Delegates of the New Hampshire Medical Society

This motion was seconded and carried

DR D G SMITH We have consulted with the Committee on Amendments to the Constitution and By-Laws, and we agree that the Advisory Committee on Medical Relief, on Child Health and on Maternity and Infancy should be special committees. There is no special committee on medical liability, as this is a subcommittee of the Advisory Committee on Jurisprudence. In order to secure a certain continuity in membership, the terms of the office of the delegates to the New England Medical Council, and of the members of the Committees on Medical Economics and on Medical Education and Hospitals were purposely arranged to expire in different years.

We approve of Dr Metcalf's ideas, relative to the changes in our annual meeting. We recommend that the introduction of the visiting delegates, the presentation of the fifty year medals and the presentation of the newly elected President be made at the banquet.

I move the adoption of that part of the report

The motion was carried

DR D G SMITH We also recommend that one morning session be devoted to the proposed round-table discussions. If, after one or two years' trial, the members approve of the round-table discussions, it may be well to have that type of meeting at both morning sessions.

I move the adoption of that part of the report

This motion was duly seconded and carried

DR D G SMITH We do not believe that a meeting of the House of Delegates at five o'clock on Tuesday, or during the evening of Tuesday, would be better attended than the present meeting held on Tuesday morning.

I move the adoption of that part of the report

This motion was duly seconded and carried

SPEAKER WOODMAN Dr Lord, may I call upon you at this time to give your report of the Committee on Medical Economics

Report of Committee on Medical Economics

In the creation of this new committee a year ago there was no exact definition of its functions. The committee seemed to be an offshoot of the Committee on Public Relations, intended to carry a part of the load of that often overburdened group. Following the implication in the name, and certain statements made before the House of Delegates as to its duties, we have attempted to select certain matters which we believe to fall within the intended scope of our work. It may be advisable in the future that this

committee shall keep in close touch with that on Public Relations in order to avoid overlapping of functions and to prevent the omission of other matters which might fall in between the work of the two committees.

Like the American Medical Association itself in reference to medical economics during the past year, this committee has not tended toward positive action or recommendation. It has seemed that in the preceding period enough action was taken so that this past year was a good time to observe how matters were working out without initiating further activity. Matters as vitally important as the fundamental principles underlying social changes as great as now being undertaken, cannot be adopted too rapidly. It is also necessary to have the majority of our members informed and in sympathy with any possible steps that may be deemed advisable. In a small and rural state like our own, conservative in temper and deliberate in its action, any changes are necessarily gradual.

The question of group hospitalization was referred to the Hospital Superintendents' Club a year ago for its consideration. In advance of a formal statement from that body we have learned that this club has instituted a special committee, composed of some of its own members, doctors, religious leaders and others, has met a half dozen times and is considering the big question of the advisability of such group insurance in New Hampshire, and the possible means by which it might be introduced. Special considerations, such as our small size, lack of large industrial groups, and so forth, have caused this committee to look very carefully into this question and it is not yet prepared to render a final decision. It looks with interest, and probably with favor, upon some step in this direction, but will require further time before reaching a conclusion.

The other special matter considered by our committee has to do with the Social Security Act. Some of our county units have already discussed this question and have apparently reached no unanimous conclusion. Many of the states are not yet in position to make use of the federal funds allotted in this act, although our state has already enacted the necessary legislation. Your committee feels that regardless of the advisability of going ahead with this scheme, it would be practically impossible at present under our financial situation in New Hampshire, to secure the funds needed to match the federal allotment and that it would have been a waste of time to ask the legislature this Spring to make any appropriation for this purpose. This practical situation leaves us free to carry on further investigation of this whole question up to the time of the next meeting of the legislature in January, 1937, or even for a longer period if this seems best.

Your committee is inclined to feel that the recommendations of certain committees of the Michigan State Medical Society in relation to the Social Security Act are well conceived and should be seriously considered if this Society is looking forward to the possibility of following the purposes of the Act.

We feel that our task is a difficult one and the questions we are asked to consider are of such paramount importance to our Society that we welcome all suggestions, criticisms and help which any of our members would be willing to give us.

DR D G SMITH The Committee on Officers' Reports recommends that this Committee on Medical Economics and the Committee on Public Relations keep in close touch with each other and divide the various problems to be studied

so that there will be no overlapping or omissions in their work.

I move the adoption of that portion of the report

This motion was duly seconded and carried

DR. D. G. SMITH We urge the continued co-operation with the Hospital Superintendents' Club, in the study of group hospitalization

I recommend the adoption of that portion of the report.

This motion was duly seconded and carried

DR. D. G. SMITH The investigation of New Hampshire's position relative to the Social Security Act should be continued by this Committee

Mr. Speaker, I move the adoption of that portion of the report

This motion was duly seconded and carried

SPEAKER WOODMAN Dr. Stewart may we have your report of the Committee on Child Health at this time

Report of the Committee on Child Health

The Committee on Child Health has studied in some detail the provisions of the Social Security Act bearing on child health (Title V parts 1 and 2). It is not our function to make general recommendations concerning this act, which involves the whole question of an increased participation by the State in the practice of medicine. However if the State is to broaden its child health work our Society is vitally interested in how this is to be done.

Let us examine the situation which this act was designed to correct. There is a growing trend toward provision by lay organizations of preventive medical services when they are not supplied by the State or not otherwise obtainable. The lay interest in crippled children with the establishment of a special society for their care is one example. Children's clinics have been established, the directors of which have not discriminated too carefully between those who could and those who could not afford private care. The right of every child to full health protection during his growing years has been set forth in the 'Children's Charter' of the White House Conference. I think we all agree to this. The desirability of the end sought is apparent but the means of attaining the end are open to question.

We agree with the Massachusetts State Committee of the American Academy of Pediatrics that supervision of normal children should be carried out in the offices of private practitioners in so far as is possible but that organized group conferences may be desirable in communities and for the use of individuals who are unable for economic or other reasons to secure adequate service otherwise. The number for whom preventive care can be secured only in this way can be reduced by a more active interest on the part of the doctors in providing it in their offices at moderate cost. We must recognize that a certain economic class of parents may reasonably feel unable to pay for the less urgent preventive care when the same people can pay moderate sickness costs. Provision by the State of free diphtheria toxoid and so forth would help some-

what. Further in view of the ease with which this type of practice can be grouped and fitted in at the doctor's convenience it might be possible to offer health service not less than sickness rates. Your Committee feels that in so far as individual effort does not take care of the situation and community conferences prove necessary to reach a group of children these should be administered at public expense under the State Department of Health with the full approval and co-operation of our Society.

Thus a federal grant enabling our State Department of Health to broaden its activities can result in a great deal of good. We believe the federal funds should not be sacrificed because of a failure to develop a satisfactory program in New Hampshire. Our Committee jointly with the Committee on Maternity and Infancy has had one meeting with Doctor Duncan at which Dr. Franklin Rogers, the New Hampshire chairman of the American Academy of Pediatrics and Dr. Ezra Jones because of his interest in the services for crippled children were also present. Doctor Duncan outlined what had been done and we offered to help in any way possible, having in mind that in some states there has been considerable co-operation among the several interested special societies and the departments of health in organizing this work.

Our Committee recommends that the Society further in all possible ways the extension of preventive care for the children of New Hampshire. By this we understand not only periodic health examinations with the correction of defects when they are found but also immunization against contagious diseases in so far as that is possible. This work is inextricably bound up with similar care during the prenatal and early postnatal weeks which does not come under this Committee.

We recommend that the Society urge the adoption by the State Department of Health of a plan which will enable New Hampshire to benefit from the funds available or which may become available under the Social Security Act for improvement in child health. This plan should provide for the addition to the department of a full-time physician. As much as possible of the child and maternal health work of the State should be under his direction.

A difficulty arises in that the health work for the school children is under the Department of Education and no funds are to be available except through departments of health but we are hopeful that this difficulty can be avoided by some administrative adjustment. Such a physician should have had special training in pediatrics. A knowledge of public health administration is also certainly desirable but may be obtained by a short course which we understand could be financed through a provision of the act after his appointment.

We recommend that the Society shall encourage the extension of preventive pediatric supervision of normal children by their private physicians. This can be aided by the preparation and distribution of literature covering very practically the subjects dealt with in health service by bringing these subjects more frequently before the local medical authorities and possibly by encouraging visits of physicians to health conferences if any are held in their neighborhoods. We also raise the question whether it might not be desirable for the State to provide free diphtheria toxoid and smallpox vaccine.

We also urge the Society to recommend to the State Department of Health the adoption of an up-to-date communicable disease code such as the United States Public Health Code to reduce somewhat the confusion resulting from conflicting instructions to school physicians and local health officers.

We recommend the appointment for next year of a committee on child health, which should be requested to prepare and distribute literature and obtain speakers on this subject for local medical meetings

SPEAKER WOODMAN The report on Child Health will be referred to the Committee on Officers' Reports. Dr. Burroughs has some information on this matter.

DR BURROUGHS A Medical Director of Maternal and Child Health in the State Department of Health is practically accomplished as a fact.

The Federal authorities have allocated the funds, the State Department has made an official plan, the man has been selected and presumably will accept, if he is offered the position. He is a member of this Society, in good standing.

This man's position, among other things, will be to clear matters of child health and maternal policies of the State Department of Health, with the medical profession. Of course, he will be a state officer. He is not going to be a federal officer, and he will not be brought in here from the outside. He will be appointed by the Governor and the Council, and be a subordinate of the State Board of Health, working as a member of the State Board of Health.

The federal people, in laying out the funds for this, had to ask some special things because the Social Security Act itself requires specifically that there should be co-operation between the State agency and medical, nursing and welfare groups and organizations throughout the State.

In order to comply with that portion of the Social Security Act, there is to be set up a committee to be called the State Advisory Committee on Maternal and Child Health. That Committee is to have medical members to represent the New Hampshire Medical Society. It is also to have members to represent these other organizations of which we spoke. Its function will be to advise with the State Board of Health and particularly with this new Director of Maternal and Child Health, on the establishment of policies in the Division of Maternal and Child Health.

In addition to that, they are asked to set up a technical advisory committee on maternal and child health, and it is requested that the State Medical Society appoint the members of the technical advisory committee on maternal and child health.

The function of this committee is to assist the director in his professional relations. For instance it is intended that if any difference of opinion should arise between the director of maternal and child health with the State Board of Health and any physician or group of phy-

sicians or any society of physicians in the state, this technical committee shall come into the picture, investigate and immediately make recommendations. It is fully expected that the director of the maternal and child health program of the State Board of Health shall follow these recommendations of the technical advisory committee.

Apparently, there is to be a new officer in the State Board of Health, who is to have the title of Director of Local Health Administration. He is to be a full-time man, a physician. The funds for this service are also allocated by the Federal people, and arrangements are practically completed. The intention, I believe, is to strengthen the local health administration, and to arrange for full-time medical health officers over larger health departments than we have at present. That is, instead of having town health officers, the idea is that we shall have either county or district health officers, and the federal people suggest that they be County Health Officers.

SPEAKER WOODMAN Dr. Wilkins, have you anything to say on this matter?

DR WILKINS It does seem to me that the committee appointed by this Society should be the same committee that is functioning now in regard to Child Welfare and Maternity and Infancy. In that way, they can co-operate with the Board of Health in the new functions.

SPEAKER WOODMAN We have a subcommittee of dentists, and I would like to hear from Dr. Littlefield.

DR LITTLEFIELD It is gratifying to us to know that there will be co-operation of the Board of Health and the State Dental Society. Heretofore, the dentistry done in New Hampshire has been carried on by the Department of Education and the Department of Health. There has been no policy developed that would give an adequate dental program.

I would suggest that two members would not be enough on such committees. We have a Public Health Committee consisting of three members. Dr. Cross from Nashua, who was a pioneer in the establishment of the dental program in Massachusetts, is Chairman of our Committee.

The New Hampshire Dental Society will co-operate with everything that the Medical Society cares to have it do along the lines of the medical profession.

SPEAKER WOODMAN Before taking any action on this matter, we should give our Committee on Officers' Reports time to examine the report.

Is there any other Committee ready to report here at this time? Dr. Blood will you kindly

give your report of the Committee on Maternity and Infancy?

Report of Committee on Maternity and Infancy

During the past fiscal year the Committee held five meetings. The full membership was present at the majority of the meetings.

At the beginning of the year a review was made of the previous years work and a vote taken that this be continued. The work of the committee has been done in co-operation with the Maternity Division of the State Board of Health.

Bulletins

During the year bulletins were sent to physicians explanatory of public health laws relating to eye prophylactics, treatment of impetigo of the new born, conclusions from the 1934 report relating to obstetrical care in hospitals, the reporting of still births, and the activities and purposes of the committee's work.

This committee recommends that

This committee (under the present name) be continued.

The present work and studies of the committee be continued.

A copy of the committee report shall be presented to the whole assembly and also that the report be mimeographed and a copy sent to each member of the society.

The committee approved.

The rules and regulations of the State Board of Health relating to licensing maternity hospitals and homes.

The new form of minimum standards of prenatal care issued by the Maternity Division of the State Board of Health.

The survey of crippled children which was made in preparation for crippled children's services under the Social Security Act.

The state plan for the extension of maternal and child health services under the Social Security Act.

Moved that

The child health work of the committee be confined to the neonatal age.

Licensed Maternity Hospitals and Homes

The committee advised and promoted an Act of the New Hampshire Legislature of 1935 transferring the licensing of Maternity Hospitals and Homes from the State Department of Public Welfare to the State Board of Health.

A questionnaire recently sent to licensed maternity hospitals shows an improvement in methods and technique which were suggested co-operatively by the State Board of Health and this committee in last year's report.

The 1936 report shows that

There are thirty-two licensed maternity hospitals in New Hampshire.

Every licensed hospital now has a special delivery room.

Masks are worn in thirty-one of these hospitals. (In one hospital masks are worn by some physicians only.)

Gloves are now worn during delivery in all New Hampshire Hospitals. (Last year gloves were not worn in five hospitals.)

In twenty-six hospitals someone remains with the patient for one hour after delivery. (Three hospitals do if indicated only.) In the other hospitals this practice is not followed.

In eleven hospitals new patients are segregated (in two hospitals only if cases are suspicious in one hospital when indicated.) Average length of segregation—until after delivery.

There are two hospitals in which nose and throat cultures are taken of all maternity cases. (In one hospital just from throat, one hospital only when physician advises, one hospital only if indicated.)

In six hospitals nose and throat cultures are taken of nurses before being sent to the maternity ward. (In two hospitals if indicated only, one hospital in times.)

Stillbirth Study

The committee co-operated with the State Board of Health in preparing a new questionnaire for the study of stillbirths. There were 271 reported and 271 questionnaires were sent to physicians reporting these stillbirths. One hundred and fifteen of these questionnaires were returned, completed, no returns were made on the other 156.

Maternity

The committee recommends a continuation of the committee's study of maternal deaths and also a study of each death through a personal interview with the physician reporting the death. All of these cases are reported to the committee by number and after study and discussion deductions are made which in the judgment of the committee seem correct. The study included the number of deaths reported by individual physicians. This past year these ranged from zero by many physicians, to one by many and not more than two by any one physician.

The committee urges that the cause of death be given correctly as this changes the picture of maternal mortality due to pregnancy and childbirth.

Maternal deaths in 1935 due to pregnancy and childbirth 45

Note: Three of these deaths were mothers who had come from border states to New Hampshire hospitals.

Causes of these deaths as given on certificate

Septicemia	12
Toxemia	9
Embolism	6
Hemorrhage	7
Ectopic Gestation	1
Cesarean	4
Other Causes	6

Note: Highest single cause of death was Septicemia

Deaths studied by Committee 40

Toxemia	10
Puerperal Sepsis	8
Hemorrhage	7
Embolism	5
Peritonitis	2
Pneumonia	1
Heart	3
Respiratory Causes	2
Postpartum Shock	1
Surgical Shock	1

In seven cases the diagnosis was confirmed by autopsies

The committee decided that in their judgment the diagnoses of five cases were incorrect. They were as follows:

Diagnoses as Given	In Judgment of Committee
Postpartum Shock	Ruptured Uterus
Hyperemesis Gravidarum	Puerperal Septicemia
Intestinal Influenza	Septicemia
Cerebral Hemorrhage	Embolism
Pulmonary Embolism	Massive Ectopic Gestation

Month of Pregnancy at Which These Cases Were First Seen by Physician

At 1 month— 2 cases	At 6 months— 2 cases
' 2 months—10 "	' 7 " — 1 "
' 3 " — 7 "	' 8 " — 4 "
' 4 " — 1 "	' Term — 8 "
' 5 " — 2 "	

3 deaths—self induced abortion, seen by physician day of death

Stage of Pregnancy at which these deaths occurred

At 2 months— 1	At 6½ months— 2
" 2½ " — 1	" 7 " — 1
' 3 " — 4	" 8 " — 2
" 5 " — 1	" Term — 27
" 6 " — 1	

These figures are approximately correct.

The responsibility for these deaths in the judgment of the Committee was placed as follows

Mother or Family	8
Probably Physician	10
Obscure	11
Unavoidable Deaths	11

In two of the studied cases the deaths, in the judgment of the reporting physician, were not due to childbirth

Three of the deaths were due to self induced abortions

Four of the deaths were cesarean deliveries

The Conclusions of the Committee were as Follows

It is advisable that cultures be taken periodically from the nose and throat of the personnel of the maternity wards, kitchen help, and all new maternity cases on admission to hospitals

Note Recently three streptococcus carriers in one hospital were found this way

That prenatal care is an important part of obstetrics—as is shown by the number of deaths due to toxemias

That the physician should seriously consider the signals during pregnancy which indicate danger and abnormalities

That there should be proper co-operation of the physicians and nursing personnel of public health agencies in the care of women during pregnancy and childbirth

The committee believes that in the changing social order the future of our profession depends largely on the study, and correction of imperfections in our practices with the good results which are sure to follow

The committee wishes to call your attention to the 1935 mortality rates of licensed New Hampshire hospitals, a copy of which has been sent to your hospitals and is there available for your information. It is interesting to note from this study that the maternity rates range from zero in the hospital having the second highest birth rate in the state to the hospital having a maternal rate of 22.2 per 1000 births. The infant mortality ranged from zero to 100.4 per 1000 living births. The stillbirth rate ranged from zero to 88.2 per 1000 births. The committee believes more than ever before that the possibilities of saving life in this field are tremendous and that every hospital should be equipped with facilities, personnel and practices to insure safety for the mother and baby within its doors.

It is the conclusion of the committee that the goal to be hoped for is that all men wishing to practice obstetrics be especially qualified for this branch of medical practice. The committee believes that obstetrics has not kept pace with surgery, that the

same general and individual ideals now applied to surgery, in so far that a surgeon will not take a classical major operation, uncomplicated, unless he is able to cope with the complicated surgical case, will in time apply to obstetrics. The public is careful to choose a man trained in surgical procedure for surgery, but for childbirth any doctor will do. Education should be directed to a correction of this attitude on the part of the public.

DR D G SMITH The Committee on Officers' Reports wishes to compliment this Committee on Maternity and Infancy for the excellent work that it has been doing in an effort to reduce the maternal and infant death rates in New Hampshire.

We do not approve of the recommendation that a copy of the report be sent to each member of the Society, but we do recommend that a summary of the report, together with the conclusions, be so distributed.

I move the adoption of that part of the report

This motion was duly seconded and carried.

DR D G SMITH We approve of the other recommendations of the Committee, namely, that it be continued under its present name, that its present work and studies be continued, and that the child health work of the committee be confined to the neonatal age.

We urge every member of the Society to co-operate with the Committee in the studies that they will make, and believe that a special effort should be made to reduce the number of avoidable maternal deaths from the 1935 total of twenty-nine.

I move the adoption of that part of the report

This motion was duly seconded and carried.

SPEAKER WOODMAN Dr Wilkins, are you ready to give us your report of the Committee on the Control of Cancer?

Report of Committee on Control of Cancer

Your committee has interpreted its functions as those which would aid the members of the society in acquiring knowledge regarding cancer control and treatment, and to co-operate with other national or state organizations or departments concerned with cancer control or cancer education.

In carrying out the first of these functions we report the following activities

1 At the 1935 meeting of the society there was displayed, through the courtesy of the American Society for the Control of Cancer, an exhibit of cancer educational material and cancer literature.

2 In the fall of 1935 there was published and distributed to all physicians in New Hampshire a "Handbook of the Early Signs and Symptoms of Cancer" giving brief descriptions of the salient clinical and diagnostic features of cancer in various locations in the body. Under each heading general suggestions regarding approved treatment were given.

The Editors of *The New England Journal of Medicine* have honored the "Handbook" by considering

it meritorious enough to publish in the issue of May 14 1936

3 One letter was sent to the members by the committee last month with a reminder of the importance of early diagnosis with special reference to laryngeal cancer

4 Several of the county societies have followed the request of the committee to devote at least part of one session to a discussion of some phase of the cancer problem The committee would greatly appreciate definite information from county secretaries regarding such activities

Your committee recognizes the necessity of a more active realization by many of the physicians in the state of the importance of early recognition of cancer This is demonstrated by unnecessary delays in taking biopsies and in failing to take advantage of diagnostic facilities which are available The laity are accepting and even asking for cancer education so it behooves the physician, not only to keep fairly well informed about cancer diagnosis and treatment, but to be able to do his part in disseminating reliable cancer facts to the public Much good can be accomplished by reiterating the warning against fraudulent cancer "cures" and by advising patients that surgery x-ray and radium are the only proved means of cure

In furthering the second function of your committee we have co-operated with the American Society for the Control of Cancer in helping to formulate plans for a state-wide educational program to be accomplished with the aid of the various women's organizations throughout the state Your president, with four other members, together with five prominent, interested lay people including the governor of the state have accepted positions on an advisory committee which will assist in this work

Co-operation with the New Hampshire Cancer Commission has been constant and throughout the year there has been an average of sixty-two members of this society taking part in the activities of the various diagnostic clinics in the state It can not fail to be of interest to the members of this society that it has been stated by several well known leaders in the cancer field that the system established in New Hampshire by the Cancer Commission is probably superior to that of any other state in the Union A number of physicians co-operated with the commission by giving thirteen broadcasts on various phases of the cancer problem during the past winter That these broadcasts were productive of good was evidenced by many requests for copies of the talks and by the statements of patients to physicians that they appeared for examination on account of the talks

DR. D G SMITH The Committee on Officers' Reports wishes to commend this committee for the excellent work that it has been doing, and congratulate it on its publication, "Handbook on the Early Signs and Symptoms of Cancer" We recommend the appropriation of Fifty Dollars (\$50.00) for the use of this Committee during the coming year

I move the adoption of this report

This motion was duly seconded and carried

SPEAKER WOODMAN Dr Henry O Smith, have you a report of the Committee on Amendments to the Constitution and By Laws?

DR. HENRY O SMITH A year ago there were

submitted to the House of Delegates five amendments to the constitution, which according to the constitution had to lie over for one year These are not controversial in their nature, they are simply a matter of phraseology

We were so confident that these amendments would be passed this year that the Secretary was authorized and instructed to incorporate them in the Constitution and By Laws as printed

Therefore, it is needless for me to say that this Committee recommends the acceptance of these five amendments, and I offer that as a motion

This motion was duly seconded and carried

SPEAKER WOODMAN Are there any further reports at this time? Dr Smith, are you ready to report as Delegate to the American Medical Association?

Report of the Delegate to the American Medical Association for 1935

The largest medical meeting ever held in the world was at Atlantic City on June 10-14 1935 It was a joint meeting of the American Medical Association with the Canadian Medical Association and had a registration of 8,469 The scientific and technical exhibits were outstanding and many excellent papers were read Your delegate served as a member of the reference committee on credentials

The House of Delegates asked the Board of Trustees to promote the enactment of federal legislation better to regulate radio broadcasting so far as the health of the public is concerned

The Board of Trustees was asked to appoint a committee to study the contraception problem and to report at the 1936 meeting

The Association is co-operating with the American Legion and the Veterans Bureau in respect to their medical problems and as a result the demand for free medical and hospital care by veterans able to pay for these services has been curtailed

Resolutions were passed favoring the restoration or continuance of R. O. T. C. units in medical schools and also the teaching of medical economics in all medical schools

It was reported that no state has passed the Epstein or any similar health insurance bill and that the federal Social Security Board does not have as one of its duties as was first supposed the studying and making of recommendations with respect to health insurance

The Bureau of Medical Economics submitted a lengthy report giving an analysis of two hundred different experiments now being conducted in an attempt to distribute medical service more equitably The general principles to be followed in the establishment of such a plan were given in detail

Two by laws were amended so that a man must be a member of a component society in order to be a member of the American Medical Association The seven New Hampshire doctors affected by this change are accordingly urged to join their respective component societies

DR. D G SMITH The Committee on Officers' Reports moves the acceptance of this report

This motion was duly seconded and carried

Report of Delegate to the American Medical Association for 1936

The recent meeting that was held in Kansas City, Mo., on May 11-13, 1936 was notable for the emphasis that was placed on the county and state medical societies. The state societies were urged to watch carefully all social security legislation, and to study its possible effect on the future practice of medicine. It was voted that all medical contracts and social security plans should be approved by the county and state societies.

It is very difficult for many physicians located near state lines to attend the meetings of the county medical society in the state in which they reside. It was accordingly urged that the state medical associations of adjoining states enter into agreements whereby physicians residing near state lines may be given the privilege of affiliating themselves with the component societies of immediately adjacent counties in other states.

It was reported that men who are serving prison terms are in some instances members of the American Medical Association. It was accordingly proposed to amend the by-laws so that these men would not be allowed to continue as members of the American Medical Association until at least twelve months had elapsed from the time that they had finished their sentences. The county and state medical societies were urged to amend their by-laws in a similar manner.

Attention was again called to the uniform narcotic act which is now in force, either in its original, or somewhat modified form, in twenty-nine states. This act was drafted by the National Conference of Commissioners on Uniform State Laws with the co-operation of the Bureau of Legal Medicine and Legislation of the American Medical Association. I believe this act should be adopted in this state. There was considerable discussion over the situation where a man who has been convicted of a violation of the Harrison Narcotic Act is allowed to continue to practice medicine. It was believed that his license should be revoked by the Board of Registration in Medicine, which may be done in this state after he has been given a hearing.

Dr. West, Secretary of the American Medical Association, urged that either the presidents of the state societies, or the delegates to the American Medical Association be sent to the secretaries' meeting held yearly at Chicago. He also urged the delegates to report to the county societies the business that the House of Delegates transacts at its meetings.

The various boards of registration in medicine were urged to raise the requirements for the graduates of foreign medical schools who seek to practice in this country. It has been suggested that all of our states should require applicants whose professional training was received outside of the United States or Canada to pass the examinations of the National Board of Medical Examiners.

It was voted that it was unethical for physicians to allow their names to be included in the various commercial directories of physicians.

It was voted to make a study of air conditioning, and its possible effect on the health of the people.

The special committee appointed to study contraception rendered an excellent report which was accepted, and it was voted that the study be continued for another year. It was voted that blood tests for paternity are not reliable. There was considerable discussion about the members of hospital staffs not being members of the county and state medical societies and it was voted that the members of staffs of hospitals approved by the American Medical As-

sociation for interne training must be members of their respective county and state medical societies. It was decided that all medical care must be separate from the group hospitalization plans, this to include medical care in a broad sense as the services of a radiologist, pathologist, etc.

The traditional stand against the professional association of physicians with the members of the healing cults was again reaffirmed. It was voted that physicians should not consult with them and should not allow them to treat patients in our hospitals.

All medical schools were asked to instruct their students on the activities, services and benefits of organized medicine.

The trustees were asked to do what they could to make the advertisements of drugs and drug products conform to the present requirements for the labels and packages of these drugs and drug products.

The very serious illness of the president-elect, Dr. J. Tate Mason, cast a shadow over the meeting. Dr. Mason, in absentia, was installed as president of the A. M. A. At this open meeting we were honored by having Governor Park of Missouri and Governor Alfred M. Landon of Kansas address us. Governor Landon said in part: "But medicine will not willingly be made the servile instrument of politicians or the instrument of domineering bureaucracy. I predict that the typical American physician and organized medicine as a whole will at no time be ready for any scheme of regimentation, for any system of impersonalized medicine which is totally alien to the best traditions of the American practitioner and of the profession as a whole." John H. Upham, who was chosen president-elect, told me that his people came from Concord, N. H., and that he will be very glad to visit us during his term of office, either as president-elect or as president of the association.

The 1937 session will be held at Atlantic City which is relatively near New Hampshire. I believe that more of our physicians should attend these meetings, which are most interesting, most instructive and very valuable not only to the general practitioner, but also to the specialist. The number of New Hampshire doctors who are Fellows of the American Medical Association, and accordingly receive the journal of that organization, is small. I wish to urge the members of this society to become Fellows of the American Medical Association which allows them to attend all the meetings of the Association and to receive the *Journal*.

DR. D. G. SMITH: The Committee on Officers' Reports believes that all medical contracts and social security plans should be approved by the state and county societies.

I move the adoption of the first part of this report.

This motion was duly seconded and carried.

DR. D. G. SMITH: The practice of allowing physicians located near state lines in a bordering state to join county societies in this State, has been allowed for some time in New Hampshire. We approve of this, and instruct our secretary to enter into agreements with our adjoining state societies whereby this practice may be continued. It will, of course, be necessary for the county medical society of the county in which the physician resides to waive its juris-

dition, as a physician can be a member of only one state association

I move the adoption of the second part of this report

This motion was duly seconded and carried

DR D G SMITH We agree that men serving prison terms should not be allowed to continue their membership in the county and state societies. We recommend that this matter be referred to our Committee on Amendments to the Constitution and By Laws for its consideration and that this Committee be instructed to draft a suitable amendment if it believes this action to be advisable

I move the adoption of that portion of the report.

This motion was duly seconded and carried

DR D G SMITH We believe that the uniform narcotic act should be introduced into the next session of our General Court and that the Committee on Public Relations should endeavor to secure the co-operation of the New Hampshire Bar Association and do all in its power to secure the passage of this act

I move the adoption of this portion of the report

This motion was duly seconded

SECRETARY METCALF The Act to which he refers was introduced at the most recent session of the Legislature, and the Committee on Public Relations voted not to support it

DR. SMITH I withdraw the motion

DR DUNBAR I move that this matter of narcotic legislation be referred to the Committee on Public Relations without recommendation for study

DR. D G SMITH I would like to amend that motion, and add "that this Committee be asked to co-operate with the New Hampshire Bar Association in this matter"

DR DUNBAR I accept the amendment

The motion with the amendment, was duly seconded and carried

DR D G SMITH The attention of the New Hampshire Board of Registration in Medicine should be called to the suggestions about raising the requirements for the graduates of foreign medical schools, and this board should be informed that our society approves of these suggestions

I move the adoption of that part of the report

The reason for that motion and statement was because of the low standard for graduation

in some of the foreign medical schools, by "foreign" I mean medical schools outside of the United States and Canada. I have a letter here from Dr Cutler replying to a request for further information in which he states that the spread between the best and the poorest graduates of European Universities is much wider than would be tolerated in the United States. In Europe, a student is left pretty much to his own devices. It is true that certain final examinations must be passed, but the student may take as much time as he pleases to prepare for them and, if unsuccessful may try again until he is lucky enough to pass. As a result of this situation, there are a great many graduates of foreign medical schools coming to this country, to engage in practice who are not properly equipped, nor properly examined by the various licensing boards in this country

That briefly gives you the background for that motion

This motion was seconded and carried

DR D G SMITH It is recommended that sometime prior to the annual meeting of the American Medical Association at Atlantic City, the Secretary should send to the members a circular letter calling attention to the meeting enumerating the benefits to be obtained by attending it and urging the members to spend that week in Atlantic City

I move the adoption of that part of the report

This motion was duly seconded and carried

SPEAKER WOODMAN Are there further reports ready tonight?

SECRETARY METCALF I have Dr Bowler's Report of the Committee on Medical Education and Hospitals

Report of Committee on Medical Education and Hospitals

At the meeting of the New Hampshire Medical Society in May 1935 the following items were turned over to the Committee on Medical Education and Hospitals by the House of Delegates

1 The inauguration of postgraduate study in some form

2 The inauguration of the speakers bureau to provide upon request speakers for meetings of the county societies

3 The utilization of teaching facilities of the State Hospital for the Insane which were offered to the Society by the Committee on Mental and Social Hygiene

4 Co-operation with the State Board of Education in its supervision of hospital training schools. We were informed that this supervision is carried out by a committee of five graduate nurses working under the State Board of Education

On these items our Committee reports progress as follows

1 The inauguration of postgraduate study in some form In the summer and fall of 1935 Pres

dent Clifton S. Abbott of the State Society contacted the Commonwealth Fund relative to post graduate fellowships and the matter was then turned over to this Committee. The Commonwealth Fund offered the Society through Dr. Clarence L. Scamman, Director of the Division of Public Health, eight postgraduate fellowships at the Harvard Medical School, each for a period of one month. The stipend offered was \$250 plus tuition, traveling expenses from place of residence to Boston and return. This information was sent to all members of the Society by a circular letter under date of January 14. To those men making inquiry a form was sent to be filled out by each and forwarded to the Commonwealth Fund. The qualifications for these fellowships were the following: that the applicant must be a graduate of a grade A medical school and a member of the New Hampshire Medical Society in good standing, must have been in practice at least five years, should preferably be under forty five years of age, and must be a resident of a community of less than ten thousand in population.

It is interesting to note that, in spite of the usual auspices and financial assistance with which these fellowships were offered, but nine members of the Society requested and filed application blanks. Although somewhat confirmatory of a lack of interest in postgraduate work among practitioners in general, the particularly small number of applicants prompted the Committee to make a brief analysis of the number of men eligible under the requirements of the Fund. We found in the *American Medical Association Directory*, 1934, that there were 130 towns in New Hampshire with a population under 10,000 in which there were registered 304 practitioners. Of these 304 but forty six were not over forty five years of age and had practiced at least five years. In other words, there were forty six men in the State of New Hampshire who under these stipulations could qualify as applicants. We have had an interesting correspondence in this connection with Dr. Scamman of the Commonwealth Fund, and hope that if the system is continued some modifications will be made in these stipulations relative to applicants from the New Hampshire Medical Society.

The fellowships for this year have not yet been granted. We expected that some time in May the applicants were to be interviewed by representatives of the Fund, following which the appointments were to have been made. We feel that it is a good start in the direction of postgraduate study in which this Committee is interested and that the interest and co-operation of the Commonwealth Fund in this field should be fostered.

2 The inauguration of the speakers' bureau. On November 14 the members of the State Medical Society were circularized by a letter, seeking the enlistment of those members willing to serve on the speakers' bureau for county meetings. With this letter was enclosed a card to be filled out by the member stating the field within which he would be willing to speak. Four hundred and fifty cards were sent out and approximately fifty replies were received. On January 30 this list was sent to each county society with a letter. No attempt was made to enlist men from outside the State, due to the obvious difficulty of making some limitation to the number to be asked and also because most out-of-state speakers for county meetings are secured through personal contact of an officer of a county society.

3 The utilization of teaching facilities of the State Hospital for the Insane. At the present time no scheme has been completed for the utilization of

the teaching facilities of the State Hospital for the Insane as offered to the Society by the Committee on Mental and Social Hygiene. We have considered it advisable to defer this matter until more direct contact could be made with the officials of the State Hospital and the Committee on Mental and Social Hygiene to learn more definitely as to the plan of the latter committee and as to whether this project should be organized by that committee.

4 Co-operation with the State Board of Education in its supervision of hospital training schools. At the suggestion of the Secretary of the Society it was deemed wise for this committee to await an invitation to meet with the committee or board operating in this connection under the State Board of Education. A letter was sent by the Secretary of the Society on September 26, 1935 to the Secretary of this committee of the State Board of Education offering the interest and co-operation of the committee in this connection.

DR D. G. SMITH. The Committee on Officers' Reports submits the following: Full credit should be given to this Committee for the inauguration of postgraduate study through the fellowships offered by the Commonwealth Fund. We most heartily approve of the attempt being made to modify the stipulations for the fellowships, so that more members of our Society will be eligible.

I move the adoption of that part of the report.

This motion was duly seconded and carried.

DR D. G. SMITH. The Speakers' Bureau should be of value, not only to the county society secretaries, but also to the men who are asked to prepare and read papers at the county meetings. We believe that the study of the utilization of the teaching facilities of the state hospital for the insane should be continued as outlined in the report of this committee.

I move the adoption of that part of the report.

This motion was duly seconded and carried.

DR D. G. SMITH. We approve the position that the Committee has taken relative to co-operation with the State Board of Education in its supervision of hospital training schools.

I move the adoption of that part of the report.

This motion was duly seconded and carried.

SPEAKER WOODMAN. May we now have the report of the Committee on Mental and Social Hygiene?

Report of Committee on Mental and Social Hygiene

The Committee has nothing essentially new to report for the past year. Considerable agitation has taken place over the matter of child delinquency, and a serious effort was made to put a law on the statute books to deal with the subject more efficiently, but the approach thus far seems to be in other directions than psychiatry.

It avails little to talk about mental and social hygiene unless means are provided adequately to deal with the problems presented and while there seems to be plenty of money for some things there does not appear to be enough in sight for the care of the feeble-minded epileptic and insane. Millions can be spent for dams, canals, better roads and new sidewalks while our State School suffers for the want of suitable provision for the care of its sick and disabled children. The institutions are expected to maintain extramural activities such as mental hygiene clinics and educational programs among the public in spite of being understaffed and without the means to increase our numbers.

During the past year an attempt has been made to cut down the population of the State Hospital by restricting the admissions to those in most acute need but little success has attended this effort as the requests for acceptance have been so urgent as to indicate that every case in most acute need

DR D G SMITH The Committee on Officers' Reports submits the following

We note with alarm the statement that 'Our State School suffers for the want of suitable provision for the care of its sick and disabled children,' and that our state hospital is still crowded. We accordingly recommend that this Society go on record as approving the appropriation of sufficient money by the State Legislature to care for our feeble-minded epileptic and insane children and adults adequately; this action to be brought to the attention of the Governor and the other proper authorities. We further recommend that our Committee on Public Relations be instructed to do all in its power to secure this necessary appropriation.

I move the adoption of these recommendations.

This motion was duly seconded and carried.

SPEAKER WOODMAN Dr Dunbar have you the report of the Neurologist?

Report of a Neurologist

The following deaths of members or former members of the New Hampshire Medical Society have been reported since May 1 1935

Brown Dr David Russell Concord N H Died May 5 1935
Remick Dr Edwin Tamworth N H Died June 2 1935
Garland Dr William R. Plymouth N H. Died June 6 1935
Mitchell Dr Abram W. Epping N H Died July 31 1935
Spear Dr Franklin E., Woodsville N H Died September 5 1935
Snow Dr Samuel D., North Conway N H Died September 19 1935
Towler Dr George H., Newmarket N H. Died October 29 1935
Thompson Dr Edward H. Hampton N H. Died November 10 1935
Senter Dr William Norwood New Castle N H Died November 21 1935
Stark Dr Maurice A., Newington Conn Died December 29 1935

Cogswall Dr Samuel J., Derry N H Died January 18 1936
Jarvis Dr Leonard M., Claremont, N H. Died January 23 1936
Connor Dr Harold J., Concord N H Died April 8 1936
Brooks Dr Harlow New York City Died April 13 1936
Tnt Dr Albert H., Hillsboro N H. Died April 21 1936
Anderson Dr Harry E. Milton Mills N H. Died April 22 1936

SPEAKER WOODMAN I believe the Secretary has the report of the Tuberculosis Committee, which I shall ask him to read to you at this time

Report of the Committee on Tuberculosis

The data relative to the mortality from tuberculosis in New Hampshire in 1935 are not as yet available. However basing our conclusions upon the general downward trend throughout the country we have reason to hope that the 1935 tuberculosis mortality figures will present evidence of a continuance of the phenomenal decline recorded in the State during the past fifteen years. We have reason to hope that the figures when tabulated will indicate that the mortality rate has continued to decline at a rate comparable with that of the preceding depression years.

The inference is inescapable that the medical machinery for the control of tuberculosis throughout the State has become increasingly effective in the prevention of the spread of the disease from the tuberculous sick to the well and the afflicted have been aided to recovery in an increasing number of cases.

In an address before the New York Tuberculosis and Health Association on February 25 of this year Dr Thomas Parran Jr. now Surgeon General of the U S Public Health Service and President Elect of the American Health Association submitted a list of what in his opinion are the nine paramount subjects and problems on public health now calling for concentration of public attention effort, and support.

"The greatest need for health action is where the greatest saving of life can be made" said Dr Parran. "First I would place tuberculosis. The tremendous decline in tuberculosis should not obscure the fact that it is still the leading cause of death in the twenty to forty age group. Our slogan used to read 'Tuberculosis is preventable, tuberculosis is curable.' I maintain that it may now be amended to read 'Tuberculosis can be wiped out in the State and Nation'.

Your tuberculosis committee wishes to present all the encouraging data which are available relative to the campaign for the prevention and cure of the disease feeling that the gains already secured in the control of tuberculosis should act as a stimulant to our energy and an urge toward a more aggressive and intensive campaign.

Meanwhile we have real anxieties. Tuberculosis is the most widespread of human infections and 165 men, women and children died from this preventable disease in 1934 in New Hampshire. While there appears to be no increase in new cases of tuberculosis yet the demands for sanatorium treatment during the past year have taxed the capacity of our two sanatoria and the waiting lists have been a cause for much concern. On May 1 the waiting list for admission to the Glencliff Sanatorium comprised a total of thirteen men and women and for the first

broke Sanatorium a total of eighteen men, women and children

The infirmary facilities at the Glenciff Sanatorium have been utilized to the limit. Additional infirmary beds are needed. Artificial pneumothorax and thoracoplasty have been carried out in carefully selected cases with encouraging results. Several lipiodol examinations of the chest have been made as well as a number of bronchoscopic examinations.

Your committee is keenly appreciative of the confidence and sympathetic co-operation which have been accorded to us by members of the New Hampshire Medical Society. This splendid spirit of helpfulness has been a large factor in the success which has attended the program for the control of tuberculosis, both in connection with the work of the sanatoria and throughout the State in the case finding and clinic and nursing service.

Dr D G SMITH The Committee on Officers' Reports submits the following:

We are glad to learn that the tuberculosis situation in this State is well in hand.

The long waiting list of thirty one individuals who desire admission to our two sanatoria is indeed a serious condition. We, accordingly, recommend that the New Hampshire Medical Society approve the appropriation of sufficient funds by the Legislature to provide additional beds at our State Sanatoria.

We further recommend that this action be transmitted to the Governor and the other proper authorities in the State, and that our Committee on Public Relations and the Committee on Tuberculosis be instructed to make a study of the situation and endeavor to obtain the necessary appropriation.

I move the adoption of that portion of the report.

This motion was duly seconded and carried.

SPEAKER WOODMAN The next report is that of the Advisory Committee on Medical Relief.

Report of the Advisory Committee on Medical Relief

Under the new setup of a State Commission in place of the operation of House Bill No 417, there has been very little concerning which the Committee has been consulted. A meeting was held last spring with the Commission and representatives of the County Commissioners but the plans then evolved have never been put into effect and so far as the Committee is officially aware its services have not been in demand either by the members of the Commission or by our membership.

Early in the year a few cases of gross overcharging were adjusted but since then we have no knowledge of how relief has been functioning, although it is our belief that the present setup is far from satisfactory.

Dr D G SMITH The Committee on Officers' Reports recommends the acceptance of this report of the Advisory Committee on Medical Relief.

This motion was duly seconded and carried.

SECRETARY METCALF I have a few councilors' reports here.

The first is from Dr J A Hunter, as follows:

As Councilor for the Strafford County Medical Society, I wish to give you the following report for the year 1935.

The Strafford County Medical Society held two meetings at the American House during the year 1935.

1 A special meeting was called April 24, 1935, by the President, Dr Manning, to instruct the county delegates to the New Hampshire Medical Society how to vote on the special problems to be presented.

- (a) Welfare
- (b) Fees
- (c) Rules and Regulations

2 A regular annual meeting, at which the officers for the ensuing year were elected and accounts settled.

At this meeting, it was moved and seconded to change the date of the annual meeting to some time in April, so that the delegates could be instructed on state problems, just prior to the annual meeting.

Dr Clifton S Abbott, of Laconia, President of the New Hampshire Medical Society, addressed the meeting.

Dr J H Blaisdell of Boston gave a talk on some practical points in the treatment of the ten most common skin diseases.

There were no new members or deaths during the year. There was one transfer, Dr Walter Rahmanop, of Dover, N H, to the Hillsborough County Medical Society.

SECRETARY METCALF The following is the report of Dr F M Dinsmoor, Councilor for Cheshire County.

Two meetings have been held during the year at the hospital at Keene, at both of which interesting and valuable papers were presented. One meeting of a social nature has been held. The society is in good condition, and there is nothing of general interest to report.

SECRETARY METCALF The following is the report of Dr T F Rock, for the Hillsborough County Medical Society.

The Hillsborough County Medical Society lost four members by death during the last year and four new members were elected and joined the society, making a membership of 140.

The fall meeting was held at the Derryfield Club in Manchester, N H. Dr C S Abbott, President of the State Medical Society, addressed the meeting in regard to the prepayment hospital insurance and the overcrowding in the medical profession. Dr G E Hoffses of Manchester, N H, read a paper on "Some Observations on the Diagnosis and Prognosis of Angina Pectoris and Coronary Thrombosis." Dr Dudley Merrill of Boston spoke on "Dangers Inherent in the Clinical Diagnosis of Cancer."

The spring meeting was held at the Nashua Country Club. Dr F E Kittredge, Vice-President of the State Medical Society, spoke at length in regard to the proposed changes in the meetings of the State Medical Society. He suggested that at least one morning session should be devoted to small group meetings, following the plan of the Maine Medical Association. Dr C R Metcalf, Secretary of the State Medical Society, was present and urged that one or two members of each county society be can-

didates for representatives at the State Legislature Dr Clifford L. Derick of Boston read an excellent paper on "Staphylococcus Infections and their Treatment" and Dr Elmer J. Brown of Manchester N. H., spoke on "The Medical and Surgical Treatment of Prostatism."

DR. D. G. SMITH We recommend the acceptance of the reports that have been made and their incorporation in the transactions of the Society

This motion was duly seconded and carried

SPEAKER WOODMAN Is there any further business or any new business to come before the House of Delegates at this time?

SECRETARY METCALF I move that we adjourn

This motion was duly seconded and carried

[Whereupon the Monday evening meeting of the House of Delegates was adjourned at eleven fifteen o'clock in the evening standard time]

MAY 26 1936

The second meeting of the House of Delegates convened at the Hotel Carpenter Manchester, on Tuesday morning May 26 1936 at eight thirty o'clock

Speaker James B. Woodman presided

The Secretary called the roll and the following members responded

The President, ex-officio
The Vice-President ex-officio
The Secretary Treasurer ex-officio
Richard W. Robinson Laconia
Francis J. C. Dube Center Ossipee
Osmond H. Hubbard Keene
Fred M. Dinsmoor Keene
Richard E. Wilder Whitefield
Robert M. Deming, Glencoff
Deering G. Smith Nashua
Clarence E. Dunbar Manchester
Charles H. Cutler Peterborough
Warren H. Butterfield Concord
James B. Woodman Franklin Falls
Harry O. Chesley Dover
Jeremiah J. Morin Rochester
Henry C. Sanders Jr. Claremont

The following alternate delegates were appointed by the President of the Society

Dr. C. F. Keeley
Dr. G. C. Wilkins
Dr. F. P. Lord
Dr. H. O. Smith

SPEAKER WOODMAN Gentlemen we shall proceed by taking up the remainder of the reports of the Committee on Officers' Reports

DR. D. G. SMITH On the report of the President the Committee on Officers' Reports submits the following

We commend the President for his report, which summarizes so well the activities of the Society during the past year. We agree with his recommendation that our meetings be held on advanced or daylight saving time, provided that the people of a majority of our cities have adopted that time.

I move the adoption of that portion of the report

This motion was duly seconded and carried

DR. D. G. SMITH We do not believe that the House of Delegates should meet more often than once a year at any previously determined time. We do believe that the President should not hesitate to call special sessions of the House whenever he deems it to be advisable.

I move the adoption of that portion of the report

This motion was duly seconded and carried

DR. D. G. SMITH On the report of the Committee on Child Health the Committee on Officers' Reports has the following recommendations

We approve of the Committee's recommendations, which in brief are as follows: That the Society further the extension of preventive care for children; that the Society urge the adoption by the State of the child health provisions of the Social Security Act; that the State Department of Health adopt an up-to-date communicable disease code; and that the Committee be continued.

I move that the first recommendation of this committee be adopted which is that the Society further the extension of preventive care for children.

This motion was duly seconded and carried

DR. D. G. SMITH We recommend that the Society urge the adoption by the State of the child health provisions of the Social Security Act.

I move the adoption of that portion of the report

This motion was duly seconded

SPEAKER WOODMAN Is there any discussion on this matter?

DR. DUNNAN The Hillsborough County Society voted that we should be very hesitant about doing anything with reference to social security that will tie us up with the Federal Government.

DR. CRONAL C. WILKINS I think that the vote referred to the large question of the Social Security Act and not to the special provisions provided for in this motion by Dr. Smith. As a matter of fact as was explained last night some

broke Sanatorium a total of eighteen men, women and children

The infirmary facilities at the Glenclyff Sanatorium have been utilized to the limit. Additional infirmary beds are needed. Artificial pneumothorax and thoracoplasty have been carried out in carefully selected cases with encouraging results. Several lipiodol examinations of the chest have been made as well as a number of bronchoscopic examinations.

Your committee is keenly appreciative of the confidence and sympathetic co-operation which have been accorded to us by members of the New Hampshire Medical Society. This splendid spirit of helpfulness has been a large factor in the success which has attended the program for the control of tuberculosis, both in connection with the work of the sanatoria and throughout the State in the case finding and clinic and nursing service.

DR D G SMITH The Committee on Officers' Reports, submits the following:

We are glad to learn that the tuberculosis situation in this State is well in hand.

The long waiting list of thirty-one individuals who desire admission to our two sanatoria is indeed a serious condition. We, accordingly, recommend that the New Hampshire Medical Society approve the appropriation of sufficient funds by the Legislature to provide additional beds at our State Sanatoria.

We further recommend that this action be transmitted to the Governor and the other proper authorities in the State, and that our Committee on Public Relations and the Committee on Tuberculosis be instructed to make a study of the situation and endeavor to obtain the necessary appropriation.

I move the adoption of that portion of the report.

This motion was duly seconded and carried.

SPEAKER WOODMAN The next report is that of the Advisory Committee on Medical Relief.

Report of the Advisory Committee on Medical Relief

Under the new setup of a State Commission in place of the operation of House Bill No. 417 there has been very little concerning which the Committee has been consulted. A meeting was held last spring with the Commission and representatives of the County Commissioners but the plans then evolved have never been put into effect and so far as the Committee is officially aware its services have not been in demand either by the members of the Commission or by our membership.

Early in the year a few cases of gross overcharging were adjusted but since then we have no knowledge of how relief has been functioning, although it is our belief that the present setup is far from satisfactory.

DR D G SMITH The Committee on Officers' Reports recommends the acceptance of this report of the Advisory Committee on Medical Relief.

This motion was duly seconded and carried.

SECRETARY METCALF I have a few councilors' reports here.

The first is from Dr J A Hunter, as follows:

As Councilor for the Strafford County Medical Society, I wish to give you the following report for the year 1935.

The Strafford County Medical Society held two meetings at the American House during the year 1935.

1. A special meeting was called April 24, 1935, by the President, Dr Manning, to instruct the county delegates to the New Hampshire Medical Society how to vote on the special problems to be presented:

- (a) Welfare
- (b) Fees
- (c) Rules and Regulations

2. A regular annual meeting, at which the officers for the ensuing year were elected and accounts settled.

At this meeting it was moved and seconded to change the date of the annual meeting to some time in April, so that the delegates could be instructed on state problems, just prior to the annual meeting.

Dr Clifton S. Abbott, of Laconia, President of the New Hampshire Medical Society, addressed the meeting.

Dr J H Blaisdell of Boston gave a talk on some practical points in the treatment of the ten most common skin diseases.

There were no new members or deaths during the year. There was one transfer, Dr Walter Rahmanop, of Dover, N H, to the Hillsborough County Medical Society.

SECRETARY METCALF The following is the report of Dr F M Dinsmoor, Councilor for Cheshire County:

Two meetings have been held during the year at the hospital at Keene, at both of which interesting and valuable papers were presented. One meeting of a social nature has been held. The society is in good condition, and there is nothing of general interest to report.

SECRETARY METCALF The following is the report of Dr T F Rock, for the Hillsborough County Medical Society:

The Hillsborough County Medical Society lost four members by death during the last year and four new members were elected and joined the society, making a membership of 140.

The fall meeting was held at the Derryfield Club in Manchester, N H. Dr C S Abbott, President of the State Medical Society, addressed the meeting in regard to the prepayment hospital insurance and the overcrowding in the medical profession. Dr G E Hoffes of Manchester, N H, read a paper on "Some Observations on the Diagnosis and Prognosis of Angina Pectoris and Coronary Thrombosis." Dr Dudley Merrill of Boston spoke on "Dangers Inherent in the Clinical Diagnosis of Cancer."

The spring meeting was held at the Nashua Country Club. Dr F E Kittredge, Vice President of the State Medical Society, spoke at length in regard to the proposed changes in the meetings of the State Medical Society. He suggested that at least one morning session should be devoted to small group meetings, following the plan of the Maine Medical Association. Dr C R Metcalf, Secretary of the State Medical Society, was present and urged that one or two members of each county society be can-

mittee on Maternal and Child Health of the State Board of Health should be the members of the Committees on Child Health and on Maternity and Infancy of this Society, and three dentists to be chosen by the New Hampshire Dental Society, that a member of our Society's Committee on Maternity and Infancy and a member of our Committee on Child Health to be appointed by these respective committees serve as our representatives on the State Advisory Committee on Maternal and Child Health.

I move the adoption of that portion of the report

SPEAKER WOODMAN This question is now open for discussion

DR. D. G. SMITH The State Board of Health has asked that these various Committees be appointed and they have asked that the New Hampshire Medical Society appoint these two Committees, the Technical Committee on Maternal and Child Health and the Advisory Committee, and that motion provides that members of our two Committees on Child Health, Maternity and Infancy, be also the members of the Technical Committee of the Maternal and Child Health Department of the State Board of Health, and that these two groups choose two men to serve on the State Advisory Committee on Maternal and Child Health

DR. COLIN STEWART Our Committee is not in favor of pushing the Society into something it does not want to adopt. The point is however, that the thing is coming, and the closer control we can keep over it the better off I think we shall be

In the recent discussion I got the impression that some of the members thought our Committee favored going out of our way to encourage the State to do things which were being done otherwise, that isn't the case at all. We would like to see all this preventive care kept under control as much as possible. We would like to do all we can to that end and we would like to see the private practitioners handle as much as possible. We would like to see the following procedure adopted as much as possible. For instance, if a well baby clinic is established, we should like to see the youngsters admitted by a card made out by the referring doctor, to the clinic, stating that the patient was unable to pay or that he couldn't see the patient, rather than just having them thrown open to everybody, no matter what the economic status

DR. BURROUGHS The substance of that motion was drawn up in conference with the Chairman of the Committee on Maternity and Infancy. It merely brings us into the position of co-operating with what is being done, at the same time leaving us free to disapprove of

anything that we afterwards may wish to eliminate

SPEAKER WOODMAN Is there any further discussion on this motion? If not, all those in favor will please signify by saying "aye"

There was a chorus of "ayes", and the motion was carried.

SECRETARY METCALF Mr Speaker, would the House of Delegates be willing to permit the Committee on Public Relations, if it saw fit, to employ a representative during the coming session of the Legislature?

I will make a motion that the House of Delegates permit the Committee on Public Relations, if it sees fit, to expend funds for the employment of a paid representative.

This motion was duly seconded

DR. DEXING Is there any program that is being put forth, or is he simply going to be there as a protectionist against whatever might arise?

SECRETARY METCALF I assume that this would be left to the discretion of the Committee on Public Relations, and that such an expenditure would be made only if in their opinion something of vital moment should come up during the session of the Legislature

SPEAKER WOODMAN If there is no further discussion, all those in favor of the motion will signify by saying "aye"

There was a chorus of "ayes" and the motion was passed unanimously

SPEAKER WOODMAN Is there any new business to come before the meeting?

DR. D. G. SMITH I should like to bring before the members of the House of Delegates the proposition that was placed before me last week, and again yesterday afternoon

There is being organized in this State, a corporation called the New England Motorists Inc., which is selling service to the people of the State. They aim to have in each city and town of any size a recommended attorney physician or surgeon and garage

On the back of the membership card of each member is this statement

In your community and vicinity, in case of accident, notify 'John Jones' of Nashua N. H. telephone . . . If you need legal advice, notify 'John Doe' lawyer. If you need a garage notify 'John Roe' garage man."

I was told that four doctors in the State had already signed up to act as physicians in this company's scheme

May I just read the section relating to first aid, emergency and medical and surgical service

"New England Motorists, Inc., will pay to any of its recommended physicians not exceeding \$50.00 for any emergency medical services or medical first-aid rendered by said recommended physicians to a holder of this contract, as hereinbefore defined, at the time and at the scene of any accident in which the above described automobile is involved or at the holder's home, or at said recommended physician's office within one hour after the happening of said accident. If a recommended physician is not available, then any other physician may be called by the holder and the obligation of this corporation will be the same."

But, as you will notice, it doesn't specify the care at a hospital, the care has to be at the home or the physician's office within an hour, or at the site of the accident.

But the part to which I particularly object is as follows:

"The applicant (that would be the physician or surgeon) agrees that in lieu of paying a cash consideration to the New England Motorists, Inc. for said exclusive listing as a recommended physician and surgeon in the territory mentioned hereinafter, to give to said organization a credit in anticipated medical and surgical services to the extent of \$100.00, on account of services to be undertaken for the members of said organization, as set out in the contract issued by the said organization."

The part last referred to is what I previously read under the heading of first aid medical and surgical service.

I would like to ask this House of Delegates either to approve or disapprove of this plan.

DR GEORGE C WILKINS I move that the employment of physicians by this insurance organization be disapproved by the House of Delegates, and the joining of it by any members of the State Medical Society be discouraged.

This motion was duly seconded and carried.

DR KEELEY How are the rest of the members of the Society going to be made aware of it? I make a motion that we send a notice to all the members of the Society.

This motion was duly seconded and carried.

SPEAKER WOODMAN Is there any further business to be brought before this meeting?

DR R W ROBINSON The Committee on Memorials and Communications has only two communications.

One of them deals with a suggestion of an old-age pension plan for physicians, with the request that we, as the House of Delegates, instruct our delegates to the American Medical Association that we advocate it. I believe that we should simply recommend no action.

The other communication deals with a suggestion made by the Committee on Contraception and Birth Control, asking us if we would not accept a speaker at one of our state meetings.

We suggest that this communication be turned over to the Committee on Scientific Work for their consideration.

DR H O SMITH Mr Speaker, in response to the vote taken last evening in relation to the request made by the delegates of the American Medical Association that the State and County Societies should so change or amend their by-laws to make provision in relation to the membership of men who are so unfortunate as to be obliged to serve terms in prison, the members of the Committee submit the following proposed new Section 4 of Chapter I of the By-Laws:

"A member who is convicted of a crime punishable by imprisonment in a state or federal prison shall be automatically expelled."

If this is accepted, the following section is to be renumbered, in order to carry it through, as would be necessary in this State:

"We recommend that the component county societies amend Chapter I, Section 8 of the model by-laws drawn up for their adoption by inserting after the first sentence the words:

"A member who is convicted of a crime punishable by imprisonment in a state or federal prison shall be automatically expelled."

DR D G SMITH I offer that as an amendment to the Constitution and By-Laws, so as to bring it before the House for action.

SPEAKER WOODMAN You have heard the amendment as read, gentlemen. That is automatically referred to the Committee on Amendments to the Constitution and By-Laws.

DR D G SMITH The Hillsborough County Medical Society has elected to Honorary membership Dr A. Guertin, Dr D C Norton, Dr F J Robinson, and Dr H L Stickney.

I move that these men be made affiliate members of this Society, Dr Guertin, Dr Norton and Dr Robinson to begin January 1, 1935.

This motion was duly seconded and carried.

DR D G SMITH Dr Stickney has asked us to recommend him for affiliate membership, or affiliate fellowship, in the American Medical

Association, therefore I move that the New Hampshire Medical Society recommend Dr H L Stickney to the American Medical Association, providing that he meets the requirements for affiliate fellowship in the American Medical Association

This motion was duly seconded and carried

Dr F P Lord I have one matter that I should like to bring before the House of Delegates. It has to do with some of our Committees and the method of selection and appointment

At the present time there exist standing committees, listed in the by laws and standing committees which are not listed in the by laws and the special committees

The Committee on Maternity and Infancy was appointed two years ago with its Chairman named, and it runs in perpetuity

The Committee on State Medical Relief was appointed in 1934 and last year was made to exist for two years more. This committee was to be appointed by the Speaker of the House

The Child Health Committee was appointed by the President in 1935 and was continued until the end of this year and you have just voted to continue it for another year. That I think, is elected

The Committee on Medical Liability Insurance, listed in our blue book went out of existence a year ago. It doesn't exist, although it gave a report yesterday

The Committee on Constitution and By Laws, appointed by the President a good many years ago has continued indefinitely

It seems to me that it would be wiser and more simple to have all of the Committees elective

Therefore, I move that these committees be elected, and that all reference to duration be stricken out

The motion was duly seconded and carried

SECRETARY METCALF I move that we adjourn

This motion was duly seconded and carried

[Whereupon, the Tuesday Morning Session of the House of Delegates adjourned at nine-fifty five o'clock, standard time until eight thirty o'clock in the morning on Wednesday, May 27 1936]

MAY 27, 1936

The Wednesday Meeting of the House of Delegates convened at the Hotel Carpenter, Manchester, on Wednesday morning May 27 1936 at eight thirty o'clock

Speaker James B Woodman presided
The Secretary called the roll and the following members responded

The President, ex-officio
The Vice-President ex-officio
The Secretary Treasurer ex-officio
William J Paul Dye Wolfeboro
Osmon H Hubbard Keene
Deering G Smith Nashua
Clarence E Dunbar Manchester
Warren H Butterfield Concord
James B Woodman Franklin Falls

The following delegates were appointed by the President

Dr Frederic P Lord
Dr George C Wilkins
Dr Cleon W Colby
Dr Charles F Keeley
Dr Thomas W Luce
Dr Emery M Fitch
Dr H O Smith

SPEAKER WOODMAN I will now call upon the Chairman of the Nominating Committee for his report on Nominations

Dr CLARENCE E DUNBAR The Nominating Committee presents this list of nominations

For President—Frank E Kittredge Elmer M Miller L O Ager
For Vice President—Samuel T Ladd Arthur W Hopkins Joseph E Larochelle
For Secretary Treasurer—Carleton R Metcalf
For Councilor for Rockingham County—Herbert L Taylor Portsmouth
Councilor for Strafford County—John A. Hunter
Trustee—Henry O Smith
Speaker of the House of Delegates—Cleon W Colby
Vice-Speaker—Richard W Robinson
Neurologist—Clarence E Dunbar
Delegate to the American Medical Association—Deering G Smith
Alternate Delegate to the American Medical Association—Emery M Fitch

DELEGATES TO NEW ENGLAND MEDICAL SOCIETIES

Maine—Charles F Nutter and Emery M Fitch
Vermont—Oscar C Young and Elmer M Miller
Massachusetts—Harry W Savage and John F Holmes
Rhode Island—Benjamin E. Sanborn and George M Crowell
Connecticut—A. Philip LaFrance and M Dawson Tyson

STANDING COMMITTEES

Amendments to the Constitution and By Laws
Henry O Smith Fred E Clow and Thomas W Luce
Control of Cancer George C Wilkins Howard N Kingsford and George F Dwinell
Medical Economics Timothy F Rock (for three years)
Medical Education and Hospitals John P Bowler (for one year) James W Jameson (for three years) and Harriis E. Powers (for two years)
Mental and Social Hygiene Charles H Dolloff
Benjamin W Baker Charles A Weaver
Publication Carleton R. Metcalf Henry H Amundsen and Warren H Butterfield.

Public Relations Frank E Kittredge, Samuel T Ladd, Carleton R Metcalf.
Scientific Work Carleton R Metcalf, Frederick P Scribner, R. W Robinson
Tuberculosis Robert B Kerr, Robert M Deming, John D Spring

SPECIAL COMMITTEES

Committee on State Medical Relief Robert J Graves, John P Bowler, Roland J Joyce
Child Health Colin C Stewart, Jr, Travis P Burroughs, F N Rogers.
Maternity and Infancy Robert O Blood, Benjamin P Burpee, Chester F McGill

SPEAKER WOODMAN Gentlemen, you have heard the report of the Nominating Committee. What is your pleasure?

DR GEORGE C WILKINS I move that we ballot for the election of the President

This motion was seconded and carried

DR HENRY O SMITH I move that the Secretary be instructed to cast one ballot for the election of Frank E Kittredge of Nashua for President

This motion was seconded and unanimously carried

SECRETARY METCALF I have cast one ballot for the election of Frank E Kittredge of Nashua as President of this Society for the ensuing year

SPEAKER WOODMAN I have received one ballot for Frank E Kittredge as President of this Society. This being the entire number of votes cast, I declare Frank E Kittredge duly elected as President of the New Hampshire Medical Society for the ensuing year

DR FRANK E KITTREDGE I thank you, gentlemen. I am fully cognizant of the honor and the compliment that you have paid me, and I am well aware of the work that will be expected of me

I never attended a meeting of the House of Delegates before Monday night, I have held practically every office in the Hillsborough County Medical Society, but I don't think I was ever a delegate from the Hillsborough County Medical Society to the New Hampshire Medical Society. But, I assure you I was very much amazed, and still am amazed at the amount of work done here Monday night, and the extent of the variety of business necessary to carry on the affairs of the Society. I am well aware, as I said, of the task which confronts us during the coming year, and I shall do all that my strength will allow me to do. That is all I can say

I do want to say just one thing more. I shall have to expect help from you gentlemen of the House of Delegates, from the Secretary, and from the incoming Vice-President, and I know I shall have that without any question

SPEAKER WOODMAN Gentlemen, what is your pleasure in the matter of a Vice-President?

DR EMERY M FITCH I move that the election take place by ballot

This motion was duly seconded and carried

SPEAKER WOODMAN I appoint Paul Dye as teller. The candidates are Samuel T Ladd, Arthur W Hopkins and Joseph E Larochelle

[After ballot was taken] DR PAUL DYE It was a unanimous vote for Samuel T Ladd, seventeen votes

SPEAKER WOODMAN There were seventeen votes cast, and these seventeen votes were for Samuel T Ladd. I declare him unanimously elected as Vice-President of the New Hampshire Medical Society, for the ensuing year

Our next order of business is the election of a Secretary-Treasurer, for five years

DR PAUL DYE I move that one ballot be cast for Carleton R Metcalf, for Secretary-Treasurer for five years

This motion was duly seconded and carried, unanimously

SPEAKER WOODMAN Having cast one ballot for the election of Carleton R Metcalf for five years, as Secretary-Treasurer of this Society, I declare him duly elected to that office

We will now proceed to the election of the rest of the list. What is your pleasure?

DR THOMAS W LUCE I move that the Secretary cast one ballot for the remaining nominees

This motion was seconded and carried, unanimously

SECRETARY METCALF I have cast the ballot

SPEAKER WOODMAN The Secretary having cast one ballot for the list of names as presented by the Nominating Committee, I declare them duly elected

DR H O SMITH The Committee on Amendments to the Constitution recommends the adoption of the proposed new Section 4 of Chapter I of the By-Laws

"A member convicted of a crime punishable by imprisonment in a state or federal prison shall be automatically expelled"

The sections following to be renumbered Submitted by Henry O Smith and Thomas W Luce

SPEAKER WOODMAN All those in favor of the motion, as stated by Dr H O Smith will please signify by saying "aye"

There was a chorus of "aves" and the motion was carried

DR H O SMITH The Committee on Amendments to the Constitution and By Laws recommends that the component county societies amend Chapter I Section 8 of the model by laws, drawn up for their adoption by inserting after the first sentence the words

"A member who is convicted of a crime punishable by imprisonment in a state or federal prison shall be automatically expelled"

The Secretary of the State Society is requested to send a copy of the vote to the Secretary of each component Society and to urge that the county societies adopt the amendment in question

This motion was duly seconded and carried

SECRETARY METCALF I was approached yesterday by the Secretary of the Women's Auxiliary who asked me whether it would be permissible for the Auxiliary to call upon the Speakers' Bureau occasionally for a medical speaker to talk not before the various county auxiliaries necessarily but before groups of women in the various communities such as the League of Women Voters or women's clubs or other organizations of that sort

DR. F E KITTREDGE I think it is something that should be encouraged. I don't believe you can find any better way of getting medical thoughts and possibly legislative thoughts, too before the women of the State not connected with the auxiliary, than this

DR WILKINS I want to approve also. I think that by this method, we can build up a considerable number of speakers throughout the State who are going to be very helpful in spreading health information

I talked to a group of women yesterday on Cancer and a cancer educational proposition. There were women there representing organizations from all over the State and I took the liberty of telling them that they could call upon the Directors of the Clinics in each separate city throughout the State for speakers. This group with reference to the Speakers' Bureau can do the same sort of good

SPEAKER WOODMAN The sentiment in this matter is obvious. The State Medical Society stands ready to co-operate

DR. F E KITTREDGE I move that the Secretary be instructed to inform the officers of the Women's Auxiliary that the Speakers' Bu-

reau of the State Medical Society will be open to them, and that they be encouraged to make use of the Bureau

This motion was duly seconded and carried

DR. PAUL DYE I move that the Committee on Medical Economics be instructed to poll the doctors throughout the State and, on the basis of their findings, draw up a minimum fee list throughout the State and that each doctor who is a member of the State Society receive a copy of this minimum fee list

PRESIDENT ABBOTT I think that is a very good suggestion, because I know there is a great variation in fees charged in different places

DR. GEORGE C WILKINS I disagree because I have had some experience in making out fee lists for the City of Manchester and for Hillsborough County. It always creates a great deal of difficulty. I don't think that a fee list that would fit Manchester, Nashua and Concord would be suitable for some parts of Coos County and even in some parts of Hillsborough County

I think that the answer to the fee list is the local fee list and not a widespread fee list that covers a large territory with a varying population and a varying income

I think that if any inquiry were to be made, such as suggested by Dr Dye, it should be made through the organized medical societies of the State, rather than through individuals

DR F E KITTREDGE I have heard fee lists discussed and discussed, but I have never seen a fee list that was ever lived up to, in fact, it was hardly ever considered

I think that every part of the state should consider its own fee list. The doctors in a community know best the conditions where they live, and we know best the conditions where we live

DR W J PAUL DYE Mr Speaker, I was asked to bring this matter up largely in the nature of stimulating some discussion inasmuch as there have been so many different fee lists. It might save disagreement in the future if there was an average list

SPEAKER WOODMAN Those who are in favor of the motion will signify by saying "aye". There was no response

Those who are of contrary mind will say "no"

There was an overwhelming "no" vote, and the motion was lost

SPEAKER WOODMAN The next item of business is the selection of the place for our next Annual Meeting. What is your pleasure?

DR. W J PAUL DYE I move that our next meeting be held in Manchester

This motion was duly seconded and carried

SECRETARY METCALF Mr Speaker, I move that a vote of thanks be extended to the Manchester Medical Society, to our guests, to the State Board of Health, to the Exhibitors and to all those who have contributed to the success of this meeting

This motion was duly seconded and carried

SPEAKER WOODMAN Is there any further new business to come before the meeting? If not, a motion to adjourn is in order

SECRETARY METCALF I move that we adjourn

This motion was duly seconded and carried

[Whereupon, the Wednesday morning session of the One Hundred and Forty-Fifth Annual Meeting of the House of Delegates was adjourned at nine-fifty o'clock in the morning on May 27, 1936]

RECENT DEATHS

TAFT—ALBERT H. TAFT, M.D., aged twenty nine, who for a little more than a year practiced medicine in Hillsboro, died at the Margaret Pillsbury Hospital, Concord, N. H., on April 21, 1936, after a short illness with a septic throat

Born in Winchester, he was educated at Winchester High School, the University of New Hampshire and McGill University

Survivors are his parents, Mr and Mrs DeForest Taft, of Winchester, three sisters, Mrs Walter Conlon, of Framingham, Mass., Mrs Willard Holt, of Epping, and Miss Alberta Taft, of Winchester

ANDERSON—HARRY EDWARD ANDERSON, M.D., died of coronary heart disease with complications at Milton Mills, N. H., on April 22, 1936. He was the son of Edward A. and Nettie Purinton Anderson and was born in Limington, Maine, April 1, 1887. He graduated from Limington Academy and was granted the degree of M.D. by Bowdoin Medical School in 1910

He began practice in Milton Mills, N. H., and continued there with one or two interruptions until 1928. He served from August to December, 1918, as First Lieutenant in the Medical Corps at Camp Greenleaf, Georgia. He was Assistant Superintendent at Ring Sanatorium and Hospital, Arlington Heights, Mass., from 1918 to 1920. In 1928, he went to Somersworth, N. H., and practiced there until April, 1935, when he retired because of ill health

On August 21, 1912, he married Miss Abbie Small, of Limington, Maine. There were no children

Dr Anderson was a member of Strafford County and the New Hampshire State Medical Societies and the American Medical Association. He was a 32nd degree Mason, a member of Bektash Temple, Nobles of the Mystic Shrine, the Odd Fellows and the Knights of Pythias, of which he was Past Grand Chancellor for the State of New Hampshire. He belonged to the American Legion Forty and Eight

He is survived by his widow, Mrs Abbie Anderson, of Milton Mills, two sisters, Clara and Helen Anderson, of Maiden, Mass., one brother, Dr Justin Anderson, of Somersworth, and an uncle, Byron S. Anderson, of Limerick, Maine

By his pleasing personality Dr Anderson won many friends both in the medical profession and the laity. His constant attendance at medical meetings showed his abiding interest in his profession and his early demise is but another reminder of the price so often paid for accepting the trials and responsibilities of a hard country practice

CHASE—EZRA C. CHASE, M.D., of Plymouth, N. H., one of the oldest practicing physicians in that section and a man widely known throughout New England because of his keen interest in his profession and in other activities, died at his home on Highland Street, Plymouth, late Monday afternoon, May 25, 1936. He had just returned from a ride and was enjoying his newspaper when the end came

Dr Chase was born in Piermont, October 10, 1857, the son of Daniel and Lavina (Clement) Chase, descendants of two of New England's old families. His early years were spent in that vicinity where he attended the public schools of Piermont. Upon the completion of the early courses of study, he began his career by working on a farm. His desire was to become a physician and finally he was able to enroll as a student of the Eclectic Medical College in Maine. At the time of his enrollment, the college had been in existence only six years and thus he had the honor of being one of the earliest graduates, receiving in 1884 the degree of doctor of medicine

He first began his career as physician and surgeon in Orford, where he practiced successfully for twenty-three years. In 1907 he moved to Plymouth where he continued his profession until the time of his death

Dr Chase was also active in civic and social affairs. While in Orford he served two terms as representative to the State legislature and as representative from Plymouth for one term. For several years he served as medical examiner for the schools of Plymouth. Fraternally he was affiliated with the Olive Branch Lodge, Free and Accepted Masons, the Royal Arch Masons, the Royal and Select Masters and the Ancient Accepted Scottish Rite and Knights Templars

Dr Chase married first, Miss Margaret Brooks and to them were born three children. Mrs Chase died in 1922. Some time later Dr Chase married Miss Minnie Ramsay, a graduate of the Woodsville Hospital training school for nurses, who served as Plymouth's school nurse for some years

Dr Chase is survived by his widow, Mrs Minnie (Ramsay) Chase, a daughter, Mrs Eda Brown, wife of Dr Lester Brown of Laconia, two sons, Dr Daniel Chase, of Orlando, Fla., and Bernard B. Chase, of Concord, member of the State Liquor Commission

MISCELLANY

A DESERVED HONOR

Science reports that Dr John W Bowler of Dartmouth College has been made Emeritus Professor of Hygiene and Physical Education

STAFFORD COUNTY MEDICAL SOCIETY

A meeting of the Stafford County Medical Society was held at the City Hotel in Rochester on April 29 1936 at 10 30 a m The meeting was conducted by the President Dr E G Marcotte The business was transacted promptly One new member Dr H. A Almond of Rochester was admitted The necrologist reported the death of Dr Harry E Anderson of Milton Mills recently of Somersworth N. H. and paid him a splendid tribute

The meeting adjourned for luncheon at 1 o'clock after which a very fine paper on Obstetrics was read by Dr Benjamin P Burpee of Manchester N. H.

EDNA WALSH M.D., Sec. clary

HILLSBOROUGH COUNTY MEDICAL SOCIETY

The twenty fourth semi-annual meeting of the Hillsborough County Medical Society was held at the Nashua Country Club Nashua N. H. on April 25 1936 T. H. Kall and John B. Wlodkowski both of Manchester N. H., were elected to membership in the society Henry L. Stuckey was elected to honorary membership and the House of Delegates of the New Hampshire Medical Society was asked to make him an affiliate member of that society The deaths of Maurice Stark and Albert E. Taft were reported and suitable resolutions were adopted W. T. Rahmanop has transferred his membership from the Stafford County Medical Society to this society

F. E. Kittredge Vice-President of the New Hamp-

shire Medical Society told of the proposed changes in the meetings of the state society and after a full discussion it was voted to instruct the delegates to act favorably on the proposal to devote at least one of the morning sessions to small group meetings following the plan of the Maine Medical Association

O. R. Metcalf, secretary of the state society said that the physicians should become more interested in politics and urged that at least one or two men from the county society be candidates for representative in the legislature

Dr Clifford L. Derick, of Boston read an excellent paper on Staphylococcus Infections and Their Treatment He discussed the subject as a whole but stressed particularly the use of the staphylococcus antitoxin and staphylococcus toxoid Dr Elmer J. Brown of Manchester N. H. spoke on "The Medical and Surgical Treatment of Prostatism" He urged a thorough study of this group of cases and stated that with proper preparation the mortality rate from prostatectomy is low

NEW HAMPSHIRE BIRTHS MARRIAGES
DEATHS AND DIVORCES IN 1935

Births reported during 1935 numbered 76797 less than were reported in 1934 Rate per 1000 estimated population for 1935 is 16.30 1934 16.58

Marriages in 1935 numbered 7322 less than in 1934 Rate for 1935 is 30.86 1934 30.69

Deaths reported during 1935 numbered 6530 an increase of 132 over 1934 Rate for 1935 is 13.70 1934 13.49

Divorces reported in 1935 numbered 763 an increase of 26 over 1934 Divorces in 1935 affected 751 minor children Divorces in 1934 affected 796 minor children — *Bulletin* New Hampshire State Board of Health

VERMONT STATE MEDICAL SOCIETY

RURAL HEALTH PROBLEMS THE PROBLEMS THEMSELVES
AND THEIR CONTROL*

BY WARD WOOLNER, M.D.†

ANYONE who has been in any way interested in the administration of a health department even in a small center knows very well that there are many health problems and that the proper method for the control of these various activities has not been discovered In our large urban centers with a full time health service, including specially trained doctors, nurses, technicians and inspectors many health problems are being controlled In many rural centers and by rural centers I mean townships and villages very little has even been attempted

to solve them In Ontario we have only one rural health center where four counties have been grouped There are forty four counties in Ontario In the United States of America, out of 2500 rural counties only one-fifth or five hundred, have any form of organized health service Only about fifty have budgets and personnel of reasonable adequacy Only about one dozen have health organizations comparable with what is considered necessary in a city

Through the generosity of the Milbank Memorial Fund with state and county assistance a wonderful county health unit has been established in Cattaraugus County in New York State Under Federal control a large part of the state of Tennessee is receiving real rural

health service Under these units the rural health problems are or will be adequately controlled These are, unfortunately, the exceptions Until state and municipal finances are in a more flourishing condition, we cannot hope to solve all our problems but we must not fail in our attempts to carry on and we must use our present health machinery to its full capacity

In discussing the various rural health problems, you will pardon me if I refer to my own work. This, unfortunately, is the only health activity I feel capable of presenting fairly accurately to you

Here are a few of the rural health problems with which we have to deal

- (1) Water Supply
- (2) Sewage Disposal
- (3) Milk Supply
- (4) Control and Prevention of Communicable Diseases, Diphtheria, Smallpox, Scarlet Fever, Infantile Paralysis, Tuberculosis, and Venereal Diseases
- (5) Prenatal Care
- (6) Medical Inspection of School Children
- (7) Laboratory Work
- (8) Social Service

Water Supply

The water supply in rural districts is largely from wells (drilled or dug) In our cities the public water supply is always under control and with any suspicion of contamination, is treated chemically usually by using liquid chlorine (The orthotoluidine test will tell us if we are using the right amount of chlorine) With one well to every four or five of our population or five hundred wells for a township of 2500 people, it is simply impossible to test annually the water, from all these wells, chemically and bacteriologically Only when we have cases of typhoid or some other intestinal disease and a cause must be found, do we test the water The water from each school well is examined yearly as part of the routine under health regulations However, the residents in our rural sections are being educated to the advantages of pure water Many farm wells today are water-tight for the upper six to ten feet and nearly all have concrete covers Our school wells are all built in this way today Thirty years ago typhoid fever was one of the diseases we were sure to be treating in the township homes in September or October Now we seldom see a case The knowledge of the care taken of the water supply in the cities and that of the school wells has spread to all rural homes and the farmer is just as anxious to keep well as the city resident Health articles in the press on water supplies and the knowledge given to the children in the schools will help to control the danger of rural water supplies

Sewage Disposal

Here, too, the rural dweller is gradually learning of the dangers to health in open pit-closets or in the otherwise careless disposal of human excreta In our rural schools we are demanding chemical closets or, where electricity is available to pump the water, we have flush closets with septic tanks The taxpayer has to pay these bills and demands to know why these innovations are required Then he learns the advantages, carries the ideas into his home and many rural homes in my township have flush closets with properly built septic tanks and disposal beds The farmer is anxious to preserve his pure water supply by proper disposal of sewage Occasionally we do have serious trouble in our townships from the deposit of untreated city sewage in our streams, but this nuisance is passed to the state health authorities to control

Milk Supply

In no part of our health work have we made more rapid strides, in recent years, than in the supervision of our milk supply At first, the milk producers and milk dealers resented the regulations for the control of milk, but today, they are nearly all anxious to co operate An accredited herd is the hope and aim of every good dairy farmer The dairies and stables from which milk is delivered to the vendors in our villages, towns or cities must comply with rigid regulations The advantages of pasteurization are known even in rural homes Whether he supplies milk to an urban dairy or to a factory the good farmer is anxious to have healthy cows, clean stables, clean milkers and sterile utensils The teaching of our pediatricians that boiled milk digests more easily than raw milk has helped to keep down milk-borne diseases in the farmer's home How few children we see today with the bovine type of tuberculosis! Surely the safeguarding of the milk supply has been responsible By the continued education of our people our milk supply is being made safe

Control and Prevention of Communicable Diseases

I cannot go over the whole field, but I will discuss a few diseases over which we have control Diphtheria should and could be one of the diseases of the past if doctors, health workers and parents would do their duty If we could immunize with diphtheria toxoid every child over six months of age and under eleven years, from 90 per cent to 98 per cent of our children would be safe from this dread disease In fact, if we gave toxoid to all the children of preschool age, diphtheria would soon die out In my own municipalities we had, in 1933, 95 per cent of all school children treated with three

doses of toxoid. Fortunately we have a health nurse whose assistance is invaluable in obtaining the consent of the parents. Refusal is almost unknown. We have always made an effort to receive the whole-hearted support of the other physicians in the community in every immunizing campaign and we find that the family doctor's goodwill helps us very materially. In rural areas we have found it necessary to give toxoid in the schools. We do feel that in urban centers the family doctor should find a larger place in the health program. In Detroit and in many other parts of Michigan where the Kellogg Foundation is assisting in health work, the family doctor is getting a chance to share in the work and in the remuneration. He sets aside a certain hour each week when the children of his clientele are sent to his office to receive toxoid, vaccination, etc. He collects a reduced but definite fee from those who can pay. The municipality pays him a small fee for others. In Vancouver, British Columbia, the family doctors are giving toxoid to all children when they reach the age of six months in accordance with a plan developed by the Department of Health of the city. Certain centers in the United States and in England are using the family doctor to assist the Health Department in this preventive work. These centers report a better feeling between the doctors and the health departments. Co-operation between the therapeutic and preventive branches of medicine should be our constant aim. In our rural work we have not undertaken to do any systematic Schick testing, knowing from numerous published papers of the highly satisfactory immunizing power of the unmodified diphtheria toxoid, which is supplied by our Provincial Department of Health. (Alum precipitated toxoid is not used in Canada.)

Smallpox

Vaccination against smallpox is carried out in the country schools on the same plan as our toxoid campaign. We tried for years to have the children vaccinated during the summer vacation but only about one per cent responded. The offer of free vaccination in the school brought us 90 per cent of the children including many of preschool age.

Scarlet Fever

It would be my opinion that generally it is now agreed that five doses of diluted scarlet fever toxin will immunize at least 75 per cent of the children (negative Dick test) and that an additional dose will raise this figure very considerably. The value is shown by Dr Hannah of the Sick Children Hospital, Toronto, in wiping out scarlet fever among nurses. It is probably not a measure for schools. It is for the practitioner to use among his families.

Infantile Paralysis

I will only mention this disease for we have as yet, neither a sure preventive nor a specific treatment. We use immune blood serum in Ontario, but I cannot see any definite results. The cases are usually in the paralytic stage when I see them or if no paralysis develops I doubt my diagnosis. We all hope some definite findings will be made soon. Few contributions to our knowledge of the epidemiology of this disease have equaled the pioneer investigations of Dr Caverly made in this state of Vermont during and following the serious outbreak of 1894. In Rutland alone 132 cases were reported and intensively studied.

Tuberculosis

This is a serious health problem in city and rural districts alike. In my early days in practice I always had active pulmonary cases under my care. Now, we send all of these patients to our county sanatorium for treatment. The contacts are visited regularly by our health nurse and taken to a clinic in a nearby city or to the sanatorium for examination and x-ray as long as seems necessary. The cost of the care and treatment of the indigent patients is borne by the municipality and provincial department of health. The rich can easily pay for their own. The large middle class of farmers and villagers who do not want charity or would be refused if they asked for help, have a serious time meeting the payment of \$1.50 a day, which may be continued over a period of years. (This \$1.50 a day is the only charge for rich and poor alike and all have the same class of rooms and food.) Surely the time has arrived in civilized Christian countries, when men need not mortgage their homes to give the sick one a chance to regain health. We should remember that the isolation of the active cases in a sanatorium may save many others in that home or in our own homes. The province of Saskatchewan with a population of 960,000 has seen the need of the state's taking full charge of the cases of tuberculosis. The health department not only provides free care in sanatoria for all but maintains an organized follow-up service as well of all contacts. After ten years of this effective effort their beds now are not all needed and their death rate from tuberculosis has dropped to 30.3 per 100,000 in 1934, the lowest rate in Canada and one of the lowest recorded anywhere. It should be remembered in this connection that the Indian population very small in numbers contributes 20 per cent of all tuberculous deaths.

Through the examination of dairy cattle and the pasteurization of milk, human tuberculosis of the bovine type occurring in children has been greatly reduced.

To control this health problem of tuberculo-

sis, I would recommend the testing of all school children with tuberculin and a further examination and x-ray of those reacting to the test. In Ontario we now demand a tuberculin test and, if it is thought necessary, an x-ray of all girls entering training schools for nurses. Studies have shown that six per cent of nurses in several general hospitals in Ontario have developed tuberculosis. I would suggest traveling clinics with portable x-ray outfits to visit all the larger cities monthly. In this way our rural cases could be examined. The state should bear the full cost of the care and treatment of all cases of tuberculosis requiring institutional attention.

Venereal Diseases

These are not a serious problem in our rural districts. We do have an occasional family with congenital syphilis but the treatment is most unsatisfactory for several reasons. Cases in country districts are best treated in a clinic supported by the state.

Prenatal Care

If mothers live several miles from the family doctor, prenatal care becomes a difficult problem. They are becoming increasingly aware of the advantages of visiting their doctors early and often. Should the mother have no means of transportation our nurse will convey her to the doctor. The co-operation of the doctor and the continued education of mothers through the press, by pamphlets and by radio together with the services of the public health nurse, are the only ways by which we can improve our problem of having every mother receive prenatal care. Forty-four per cent of the maternal deaths in rural Ontario in 1933 had not had prenatal care, eighteen per cent had had Caesarean section.

Medical Inspection of Children in Rural Schools

Our provincial regulations require the medical officer of health to make annually, a careful inspection of the school premises but the school children are not necessarily included. However, I feel that the children in rural schools

have the right and often have more need of a medical examination, than their city cousins.

Our people are usually anxious to have the defects found and corrected. The only solution for the medical inspection of children in rural schools is a full-time county health service.

Laboratory Work

Branch diagnostic laboratories have been placed in a number of the cities in Ontario supplementing the services of the Central Provincial Laboratory. No doctor is many hours from a center where his needs may be promptly supplied. These laboratories supply us with many biological products including insulin, liver extract, various antitoxins, toxoid, vaccines, arsenical, bismuth and mercury preparations as well as diagnostic outfits for mailing blood, urine, fecal matter for suspected typhoid swabs, from throats and blood for sugar or culture and so forth to the laboratory.

Social Service

This is not so serious a problem in rural districts as in our large cities. Since 1930, with many families receiving relief, our health nurse is forced to spend many hours a week among these people. A county health service could correlate the work of various social agencies and co-operate in the provision of medical services.

Finally, if we are to solve these many rural health problems there are certain definite goals for which we must strive.

- 1 Health departments must work with and receive the full co-operation of the family doctors.
- 2 We must have, as soon as possible, full time health services financed jointly by the state and the municipality.
- 3 In rural areas the county health service seems the logical unit. The Cattaraugus County Unit demonstrates what can be accomplished.
- 4 The state should accept full financial responsibility for the care and treatment of pulmonary tuberculosis.

MEDICAL PROGRESS

PROGRESS IN PSYCHIATRY FOR 1935

BY JACKSON M. THOMAS, M.D.¹

THOUGH the field of psychiatry cannot boast of any astounding discoveries during the year 1935 it has continued to accumulate data which add to our understanding of the multitude of factors that enter into the formation of human personality. Contributions from investigators in many fields and improvements in technique continue to be put before the psychiatrist.

In the field of therapy one of the most significant advances in psychiatry is the fever treatment of dementia paralytica. It is well established that cases of dementia paralytica are benefited by malarial fever but the mechanism through which this mode of treatment operates remains a source of controversy. The hypothesis that the elevation of temperature is responsible for the favorable therapeutic results in these patients has instigated the development of a variety of mechanical fever producing devices. The diathermy method has been peculiar in many clinics.

What seems to be a fair summary of our present knowledge of this form of treatment has been recorded by Epstein, Solomon and Kopp.¹ Together with a series of their own cases these authors have tabulated the reports of all the series of cases of dementia paralytica treated with diathermy and related forms of mechanically produced hyperpyrexia. The results vary greatly. The extremes in the variations may be noted in the report of Freeman Fong and Rosenberg who observed no good remissions in a series of fifty cases and the results of Neumann and Koenig, who reported twelve good remissions and thirty-eight partial remissions out of a total of fifty cases treated with diathermy. In all Epstein, Solomon and Kopp collected 648 cases from the literature. Of this number 177 cases were considered to have good remissions and 260 cases as having partial remissions.

From their own series of thirty-three cases who were given diathermy between February, 1931 and February 1934 and whose therapeutic results were analyzed in February 1935 Epstein, Solomon and Kopp found that eight patients improved and returned to work, seven improved but not to a degree that would enable them to be self-supporting. Four patients, while remaining hospitalized were judged to be improved. Four patients showed no improve-

ment and ten died. One case out of the series suffered a clinical and serologic relapse four years after diathermy treatment. There was a correlation between the clinical status and the reaction of the spinal fluid. In comparing their clinical results in patients treated with malaria, artificial hyperpyrexia and tryparsamide these investigators observed the best remissions in about 45 per cent of the cases treated with malaria in 42 per cent of the cases treated with tryparsamide and in only 27 per cent of those who received artificial hyperpyrexia. Twenty-two per cent of the diathermy series showed normal spinal fluid following treatment while 37 per cent of the spinal fluids were rendered normal in the cases treated with malaria and tryparsamide.

Epstein, Solomon, and Kopp concluded that artificial fever produced by diathermy is of value in the treatment of dementia paralytica but in the manner in which they used it this form of treatment is not so efficient as malaria. From a practical aspect they call attention to the many complications which may arise in the method of diathermy.

That induced hyperpyrexia is of little value in the treatment of the manic depressive and schizophrenic reactions has been called to our attention again in 1935 by Somogyi² of Budapest.

Improved methods of encephalography have increased efforts to discover gross pathological changes in the psychoses. In the psychoses which are recognized as being symptomatic of organic brain disease the encephalogram has proved to be of immense confirmatory and localizing value. Cortical atrophy and ventricular changes associated with cerebral arteriosclerosis, senility, chronic alcoholism, epilepsy, brain tumor, and subdural hematoma are well known. On the other hand investigators working with schizophrenic and manic depressive psychoses have presented us with some very uncertain data. For example Rudolf Lenke,³ working in the Psychiatric and Nerve Clinic of the University of Jena asserts that out of 100 schizophrenics on whom he did encephalograms eighty-four showed abnormal cortical findings. Fifty of these eighty-four patients exhibited an internal hydrocephalus. A comparison of the lateral ventricles as depicted by the encephalogram, showed no definite asymmetry in all cases—in the majority of the cases the left ventricle being the larger of the two.

From this material Lenke assumes that the

¹Th. Max. J. Kopp, M.D.—Chief, Medical Officer, Boston P. H. Pathol. Report 1-1-35 and address of the author. This work was done in 1935.

gravity of the disorder (schizophrenia) runs parallel with the encephalographically depicted brain anomalies, but he emphasizes that the duration of the schizophrenic process and the ventricular and cortical changes are independent of each other. Repeated encephalograms done at long intervals upon the same patients showed no variations from the original findings, despite the fact that the disease process continued to grow worse. "These two important results of my investigations, the independence of the encephalographic findings from the duration of the process and the negative results of repeated encephalographic studies lead me to the assumption, that the asymmetry of the brain ventricles, their frequent dilatation and the often encountered cortical changes have not developed secondarily, that they are not results of the schizophrenic process but exist as predisposing factors."

that these brain anomalies influence the course of the schizophrenic disorder unfavorably." Lemke regards the anomalies as being congenital in origin and believes that when they are noted in the presence of tainted heredity and eccentric prepsychotic personality traits they connote an unfavorable prognosis.

In this country Moore, Nathan, Elliott, and Laubach⁴ have reported encephalographic studies on schizophrenia, as well as other psychoses. These authors also report definite ventricular and cortical changes. Their findings are at variance with those of Lemke. For example, Lemke found no alterations in the encephalographically depicted anomalies when the examinations were repeated on the same patient eight years after the first studies. Moore and his associates noted that five of their series of seventy-one patients who had repeated encephalograms "deteriorated in characteristic praecox fashion during the interval of encephalography." The second set of encephalograms in these patients show an increased pathology in the form of further enlargement of the ventricular systems and cisterns and in some cases increased cortical atrophy.

If we bear in mind the complexity of the schizophrenic disorder, the multitude of pathological sections of brain from these patients which have failed to exhibit any constantly recurring anomalies and the number of difficulties arising in the technique of performing and interpreting encephalograms, we will not be misled by reports such as these of Lemke and Moore. So far as I know there is no recorded series of accepted normal encephalograms, and until we are more certain of the appearance of normal variations in encephalograms I think we are treading upon thin ice if we assume that unusual encephalographic findings in schizophrenia always indicate gross brain pathology. A recent review of 800 encephalograms by Lemere and Barnacle⁵ emphasizes the multitude

of normal variations to be encountered in encephalograms.

Those interested in the problem of psychiatric classification will find Rachlin's⁶ follow-up study of Hoch's benign stupors of much interest. Hoch's well-known Monograph appeared in 1921. This work depicts a series of cases manifesting psychoses characterized by inactivity, apathy, negativism and disturbance of intellectual functions. Often these symptoms were accompanied by slight elevations in temperature, leucocytosis and ideas pertaining to death. Hoch removed these cases from the schizophrenic group, classified them with the manic-depressive reactions and gave them a good prognosis. In November, 1935 Rachlin published a follow-up study of Hoch's cases. The majority of the patients living at that time were between forty-five and sixty years of age. Of the forty cases referred to by Hoch, Rachlin has been able to identify nineteen through hospital records (Manhattan State Hospital), but he succeeded in tracing only thirteen. Of the thirteen traced nine are living (six are in state hospitals), three are residing in their homes (1934), and four died (two died in state hospitals and one was deported to Ireland). The readmission of so many of the cases to hospitals and their subsequent courses led Rachlin to reclassify many of Hoch's cases with the schizophrenics. For details of Rachlin's follow-up study it is suggested that those who are interested in stupors consult his article after re-reading Hoch's Monograph.

It is futile to become involved in a discussion as to whether a case is manic-depressive or schizophrenic. These terms carry almost as many different connotations as there are clinics working with psychotic patients. For this reason I see little to be gained by reclassifying Hoch's cases with the schizophrenics as Rachlin has done. What seems more important is the fact that the great majority of Hoch's cases experienced remissions of long durations (one patient as long as twenty-five years and others ten to fifteen years except for brief periods). Certainly there are other types of stupor reactions which are not followed by remissions of this nature. Hoch's stupor cases may not have run such a benign course as he thought they would undergo, on the other hand, we should not forget that Hoch recorded a masterful description of a type of reaction with which we are familiar today.

In 1929 Huhnerfeld⁷ injected hematoporphyrin, a photosensitizing decomposition product of hemoglobin, into rabbits and found that after ten minutes they became livelier, reacted strongly to stimuli and showed no fear. This same investigator later treated depressive psychoses by means of hematoporphyrin (photodyn) and reported favorable results. Since the publica-

tion of Hinshelwood's work, foreign literature has contained several favorable reports of hematomorphin therapy. In this country Strecker Palmer and Braceland⁸ have published favorable results. Of the 1935 reports of Notkin Hildart and Dennes,⁹ Steinberg¹⁰ and Angus¹¹ only Angus was impressed by the use of hematomorphin in depressive psychoses. Out of a series of forty-one cases "whose chief symptom was depression" this investigator found that six manic depressives, one schizophrenic, and one psychoneurotic recovered or were much improved. Of the balance ten were improved, five showed slight improvement and eighteen were unaffected.

Notkin treated ten cases of schizophrenia and ten cases of involuntional melancholia with hematomorphin. Only one case in the melancholic series showed any considerable clinical improvement, three showed mild transitory improvement, none of the schizophrenics improved. Steinberg's series of fourteen cases included only two who could be regarded as improved and one of these suffered a relapse six months later. With Witelhorn, Anthonisen and Rose I observed a limited number of depressions (McLean Hospital) who received hematomorphin treatment. During the treatment only one patient improved but since she had recovered from a previous depression in approximately the same period of time without drug treatment we could not attribute her second recovery to hematomorphin. The control of drug treatment in the manic depressive psychoses is exceedingly difficult. So many of these patients recover without any specifically directed form of treatment even after they have remained in institutions as long as ten years, we must be extremely cautious in attributing improvement or recovery to a drug until all of the variables have been weighed carefully.

The remarkable electrical disturbances arising in the brain, the potential oscillations or "Berger rhythm" of Adrian continue to occupy the attention of many investigators. It seems well established that these potential waves which were recorded first in man by Hans Berger in 1929¹² arise in the cortex but there still persists considerable difference of opinion concerning the locality of their origin. Berger continues in the belief that every part of the cortex, when active, gives rise to potential waves with a frequency of about ten a second. Their disappearance when the eyes are closed is due, according to Berger, to a widespread inhibitory effect which interferes with a perception of the potential changes through the skull. This view has been criticized by many investigators, especially Adrian and his associates who have suggested that "the rhythm is a spontaneous or resting discharge from a large group of neu-

rons in the occipital lobe neurones mainly concerned with the vision." Adrian and Matthews¹³ argue that the active region must be concerned with vision because in their studies they have found that the rhythm is abolished most effectively when the eyes are open and there is a presence of visual stimuli, also because exposure of the eyes to a flickering field results in potential waves with the same general distribution over the head but with the frequency of the flicker instead of the usual ten a second frequency.

In 1935 Adrian and Yamaguchi¹⁴ reported a series of experiments which they believe resulted in evidence that further confirms the assumption that the potential changes reach a maximum in the occipital region. Limited space will not permit a detailed review of their experiments. It suffices to say that they are more or less in confirmation of Adrian's and Matthews' earlier work. Berger¹⁵ himself has continued the controversy in an article appearing in the *Archiv für Psychiatrie und Nervenkrankheiten*. Here he calls attention to the variations in applying the electrodes and emphasizes that this may be a factor in the results which have led to different explanations of the phenomena at work. He takes issue with Adrian and Matthews' inability to detect the potential waves in people who have been blind for many years and presents electro-encephalograms showing the waves from three subjects who suffered complete blindness for fifteen, seventeen, and eighteen years. To explain the discrepancy between his results and those of Adrian and Matthews, Berger returns to their argument as to whether pattern vision or the process of simple attention prohibits a detection of the rhythm. Adrian and Matthews have assumed that "the area is so much a part of the visual apparatus that when vision (particularly pattern) is cut off there will be nothing left to disturb it. But an intense activity in the rest of the brain will do so and it seems that if vision is permanently cut off the area is not allowed to remain idle but becomes gradually more and more accessible to excitation from other parts." Thus seems to be Adrian and Matthews' explanation for their failure to obtain the Berger rhythm in the blind. On the other hand, Berger who did detect the rhythm in blind subjects is of the opinion that the abolition of the rhythm involves chiefly the process of attention, that by careful consideration of the psychological and sensory factors, particularly hearing through which the blind orient themselves to the experimental set up, one should be able to reduce attention to a minimum and thereafter detect the rhythm. Berger obtained the rhythm in one of his subjects who was blind deaf in one ear, and had the sound ear plugged with cotton.

In this country Gibbs, Davis and Lennox¹⁶

have utilized the electro-encephalogram in studies of epilepsy and conditions of impaired consciousness. With them leads the most constant and pronounced fluctuations noted in the resting subject displayed frequencies of ten to twenty a second and reached a maximum of sixty microvolts. In sleep the frequency of these waves decreased to one and five a second. Sometimes the amplitude of the waves decreased. Groups of large slow waves were detected in subjects suffering frequent attacks of petit mal epilepsy, they were associated with the seizures. Grand mal epileptic seizures were preceded by the gradual appearance of waves with a higher frequency than the previously dominant waves. There was an increase in the amplitude of the waves and the convulsions began. Until the clonic phase began the wave amplitude continued to increase, but the frequency did not alter. As the clonic phase set in, fast waves tended to clump together into slower waves—as the convulsive movements ceased the amplitude and the frequency of the waves decreased. These investigators also observed that if subjects became unconscious by breathing nitrogen or from failure of cerebral blood supply, the frequency of the waves decreased and the amplitude increased.

The report of the American Neurological Association's Committee for the investigation of sterilization appeared in June, 1935. The Committee was composed of Drs. Abraham Myerson, Chairman, James B. Ayer, Tracy J. Putnam, Leo Alexander and Clyde E. Keeley, consultant in genetics. Their report is a full one and appears in monograph form. Since *The New England Journal of Medicine*⁶ has published in an earlier number a review of the report it seems unnecessary here to do more than refer those who are interested in the matter of sterilization to the Committee's original report.

The results of Cannon's¹⁷ experiments in which he showed that a rise in blood sugar occurs in cats when these animals are frightened by a barking dog have been confirmed by many investigators, but attempts to detect similar elevations of the blood sugar content in man while he is disturbed emotionally have resulted in conflicting reports, particularly in the case of "normal" man.

Bowman and Kasanin¹⁸ and Whitehorn¹⁹ have reported the blood sugar findings in patients experiencing emotional disturbances during the course of mental disease. These investigators are essentially in agreement that there is no correlation between the mood of the patient and the height of the blood sugar. The blood sugar levels of emotionally disturbed subjects suffering mental disease were usually within normal limits during fasting states. When elevations were noted in these patients the clinical

picture usually included evidences of organic disease (fever, diabetes, arteriosclerosis). Bowman and Kasanin believe that these factors were more concerned with the rise in blood sugar than was the emotional state of the patient. Recently, Gildea²⁰ and his associates have studied blood sugar levels in "normal" subjects and mentally ill patients who experienced disturbing emotional states. These workers observed that "the only normal subjects in whom we could consistently find a substantial elevation in the sugar content of the blood were those who had been through profoundly disturbing experiences which aroused a genuine fear of death or other catastrophe either for the individuals themselves or for a person whom they loved." An elevation of the sugar content of the blood in patients with manic-depressive psychosis, schizophrenia and psychopathic personalities was rarely observed. This latter finding is in keeping with the earlier works of Bowman and Kasanin, and Whitehorn. Gildea²⁰ and his associates suggest that the failure of the blood sugar to rise in severe emotional states occurring in patients suffering mental disease indicates that these reactions may be "qualitatively different from the externally similar disturbances in people without mental disease."

Concerning the nature of this qualitative difference they speculate as to the possibility of the psychopathic personalities playing dramatic rôles without disturbing or taxing their metabolic processes. They are more cautious in speculating about the manic depressive but raise the question as to whether the fact that these patients do not mobilize their carbohydrate to any marked extent may partially explain why it is possible for them to show extreme emotional disturbances for long periods of time without becoming exhausted. Reference to what may happen in the schizophrenia whose blood sugar does not rise in disturbing emotional states is omitted.

In regard to blood sugar studies in disturbing emotional states of psychotic subjects, I think the instigators whom I have cited will agree to the statement that when we attempt to compare the laboratory findings in animals which have been subjected to death-threatening experiences that must be accompanied by the most disturbing of emotions, with the results obtained in studies of emotional states of psychotic patients, our task becomes extremely complex. In the first place, it is indeed rare to encounter disturbing emotions in the human being, in health or in mental disease, which may be said to be analogous to the state of a cat when it feels that its very life is about to be snatched away. Moreover, there is evidence to suggest that one of the rôles of certain psychoses is to bind or dissipate some of the unpleasant and disturbing physiological com-

ponents of emotion. It may be that fancied death threatening enemies are capable of instigating the same disturbing emotions which an objective and palpable one arouses but in my clinical experience such states are extremely rare in the manic depressive and schizophranic psychoses. The verbal introspective accounts of these patients are often misleading—as the physical components of their emotions illustrate. At times the fear states of the toxic psychoses (acute alcoholic) seem to approach the genuine fear states of the frightened laboratory animal.

Among the new psychiatric books appearing in the English language in 1935 special attention should be called to Konner's "Child Psychiatry," Campbell's "Destiny and Disease in Mental Disorders" and Alexander and Healy's "Roots of Crime." Limited space will not permit a satisfactory review of these books here.

Kanner's "Child Psychiatry" is a textbook the first of its kind in English. The general trend of the author's approach to the problems of the child is in keeping with Adolf Meyer's teachings. The pediatrician as well as the psychiatrist, will find much of interest in this book.

Campbell's "Destiny and Disease in Mental Disorders" outlines the author's views with regard to the so-called endogenous psychoses but especially those referred to as schizophrenia. The reader will find the views expressed in this book very stimulating. They emphasize the complexity of the manifold life experiences which are so often relegated clinically to the limbo of schizophrenia.

"Roots of Crime" is a volume dealing with psychoanalytic studies of established delinquents. The authors present detailed analyses of personalities which illustrate some of the unconscious forces at work in these people. This book represents one of the few serious of

tempts to understand the personality factors involved in crime. The life histories of Richard Vorland, Sigrid Amanson, Henry Elton, and others referred to in the book will have to be read to obtain the full significance of the authors' views concerning the roots from which crime springs.

MAJOR RECOMMENDATIONS*

The mental health of a community requires the services of experts dealing mainly with the individual case. To conceive of a mentally healthy community without adequate and expert leadership and assistance is to believe merely in the value of verbalistic ideologies. Mental health can be most effectively accomplished by having practical concrete service available.

The most significant observation of the survey in regard to Springfield was lack of just such adequate mental hygiene service and leadership in the face of an increasing and intelligent demand for it from social health and educational agencies and from individuals. The major recommendations of the survey are therefore: (1) Provision for additional clinical service for the public school system

as previously stated and (2) Enlargement of the present child guidance clinic at the Springfield Hospital which operates on a part-time basis to a full time clinic giving service to both adults and children with an adequate staff and with a psychiatrist especially trained in child psychiatry at its head. As the survey believes that a local community should bear part of the expense of its own mental hygiene clinic and should not expect the State to bear the entire financial load, it recommended that Springfield share about one-fourth of the expense of the clinic, with the State taking care of the balance. The survey also recommended that this new clinic be given the advantage of an advisory and sponsoring committee in which the Monson and Northampton State Hospitals, the Belchertown State School, the State Division of Mental Hygiene, the Springfield Academy of Medicine, and the Council of Social Agencies should be represented.

CASE 22261

PRESENTATION OF CASE

A fifty-three year old American businessman was first seen complaining of jaundice

Six years before his initial visit he developed loss of weight, increased thirst and polyuria. Two months later he went to a hospital where his urine was found to contain 48 per cent sugar and his blood sugar level was 190 milligrams. A night urine specimen contained 50 per cent sugar. He was given 10 units of insulin three times daily and within twenty-four hours his urine became sugar-free. At the onset of his illness he weighed about 190 pounds and three months later his weight was 166 pounds. At this time he was taking 8 units of insulin once daily and his urine was sugar-free. His blood sugar, however, was 210 milligrams. Four months later his blood sugar was 160 milligrams and three months after that 130 milligrams. At this time he weighed 152 pounds but he had remained upon a rigid diet since the onset of his illness.

Four years ago he was found to be jaundiced and was again admitted to a hospital. There were no associated symptoms but the van den Bergh test showed 2 milligrams per cent of bilirubin. The blood showed a red cell count of 3,700,000 with a hemoglobin of 70 per cent. The fasting blood sugar was 140 milligrams and examinations of the urine were negative except for the presence of bile. An x-ray examination of the chest showed slight increase of the lung markings and calcified hilar lymph nodes but was otherwise negative. A gastrointestinal series and barium enema were negative except for a concavity at the splenic flexure consistent with an enlarged spleen. He remained noticeably jaundiced for several months and finally improved after the removal of some upper teeth. Thereafter he remained well for about three years and then had several infected teeth extracted. Shortly after this he developed jaundice, chills, fever, crampy sensations in the abdomen, and tenderness in the right upper quadrant. Physical examination showed him to be deeply jaundiced. The lungs were clear and the heart was negative. The abdomen was dis-

tended and firm but no definite tenderness or spasm was elicited. The liver edge was not felt but the spleen was readily palpated. The temperature was 103°, and the pulse 96. Although his urine was sugar-free he continued to take five units of insulin daily and to adhere to his diet. The insulin was discontinued and he was given a high carbohydrate diet. The temperature then rapidly returned to normal and the icterus disappeared. He returned to work and remained well except for occasional fever and sensations of abdominal distention until eight months later, at which time he developed chills, a fever of 102°, and some midabdominal discomfort. Despite the fact that he was eating a high carbohydrate diet and subsequently received much glucose intravenously his urine contained no sugar. At this time the liver was not felt but the spleen was enlarged two finger breadths beneath the costal margin. An icterus index was 29. X-ray examination of the abdomen was negative. He was given daily glucose infusions and in five days his icterus index fell to 19. At the end of this period he began to develop edema and ascites and the infusions were discontinued, after which his icterus index rose to 32 but he became much less waterlogged. He remained icteric for about three months but felt quite well otherwise. His urine and stools consistently contained bile.

He had a perforated gangrenous appendix sixteen years before entry. No story of chronic alcoholism or drug ingestion was obtained.

Physical examination showed a poorly nourished, slightly jaundiced man. The tongue was smooth at the tip, at which point a wart-like bud protruded. There were small telangiectases over the right chest but the heart and lungs were normal. The liver was readily palpated two finger breadths beneath the costal margin. Its edge was sharp and smooth. The spleen extended three finger breadths beneath the costal margin. No edema or evident ascites was noted.

Examination of a urine specimen showed a specific gravity of 1.013 and a slight trace of albumin. There was no sugar in a twenty-four hour specimen. Urobilinogen estimation was reported as 1/20. Examination of the blood showed a red cell count of 3,470,000, with a hemoglobin of 60 per cent. The white cell count was 5,950. A serum protein was 7.1 grams per cent, of which the albumin was 2.87 and the globulin 4.28. A liver function test showed 50 per cent dye retention. The van den Bergh was 3.9 milligrams. A sugar and fat tolerance curve showed the following:

	Sugar	Fats	Choles terol	Esters
Fasting	125	360	260	94
1/2 Hour	125	409	200	104
1 Hour	146	412		
2 Hours	129	357		

The patient continued to be comparatively well for about six months, when he developed an acute upper respiratory infection. Severe terminal jaundice appeared and he died within a few days.

DIFFERENTIAL DIAGNOSIS

DR ALFRED KNABES In reading over this story one is faced with two problems. In the first place, what was the nature of the illness which caused recurrent jaundice, chills, fever and abdominal pain over a period of about four years and which ultimately caused death? The second, and, it seems to me, more interesting problem is why as this disease progressed did his diabetes disappear? In regard to the first problem the nature of his fatal illness he came under observation four years before his death and at that time he had a period of asymptomatic jaundice during which the only abnormal finding aside from the jaundice was a slight anemia and an enlarged spleen by x-ray. He was studied pretty thoroughly at that time. I do not quite see why all the gastrointestinal x-rays were taken and I am a little surprised that no Graham test was done although it might not have revealed anything in the presence of jaundice. That illness it seems to me was consistent with a mild attack of hepatitis of some sort, either infectious or toxic. Just what the cause was, we cannot say. I can see no reason for believing he had gall stones or any other disease of the major biliary ducts. A mild hepatitis would best explain that initial picture from which he recovered and remained well during the next three years.

Then he gets a series of illnesses during which he had recurrent and fluctuating jaundice, abdominal discomfort, fever, chills, and at one stage of which he becomes water logged. Now of course, the first thing one thinks of in the presence of liver disease, which the patient undoubtedly had, and, in addition diabetes, is hemochromatosis. The association of the two seems to strike one but I cannot see any way of substantiating that diagnosis. There is no mention in the record of abnormal skin pigmentation and I think the chief point against the diagnosis is that the diabetes got better instead of worse, which is contrary to what one would expect with progressive pigmentary cirrhosis. If he had hemochromatosis it seems to me that the pancreatic cirrhosis which accompanies it and which is responsible for the diabetes usually progresses along with the liver disease and although the diabetes may be mild or severe, depending on the amount of pancreatic cirrhosis it rarely clears up as the disease progresses, so that I think hemochromatosis is unlikely.

Could he have had gallbladder disease? Obviously the people who were taking care of him did not think so or he would have been operated

on. There are a number of things against gall bladder disease in this case. In the first place he starts out with asymptomatic jaundice and enlargement of the spleen, an unusual picture for either cholecystitis or cholelithiasis, and as the disease progresses the spleen becomes increasingly larger. The progressive splenic enlargement argues very much against primary disease of the gallbladder. As I see it it is regrettable that no Graham test was done but perhaps those who took care of him thought that inasmuch as he retained fifty per cent of the bromsulphthalein at the end of a half hour the chances were that he would not have excreted much of the gallbladder dye and the Graham test would therefore only serve to confuse the picture. On the whole I am inclined to think that the gallbladder and the larger bile ducts at any rate will probably be normal. Moreover if any stones are found they probably do not explain the severe liver damage from which this patient obviously suffered. I do not think one can exclude however, diffuse intrahepatic lithiasis which can conceivably cause a picture of this sort and which I do not see how one can diagnose. All we can say is that it is consistent with the picture but very unlikely. Other conditions like carcinoma of either the pancreas or bile ducts I think are very unlikely in view of the enlarged spleen which one very infrequently sees with primary or metastatic malignancy of the liver or gallbladder.

Can he have had a diffuse cholangitis and cirrhosis as a result of it? Possibly, but just what the nature of that process was that took place during that year and a half preceding his death I do not believe we can be sure of, because the patient died six months after he recovered from that illness and all we shall find will probably be the resultant scars, the precursors of which we can only speculate about. I think the most likely possibility is that the patient was suffering from severe progressive necrosis of the liver and that he finally ended up with a small nodular cirrhotic liver. Whether it was infectious or toxic I do not see how we can say. But the end result of the picture was as I saw a cirrhotic liver. It is the result of what we might call a subacute yellow atrophic cause unknown.

There are some interesting laboratory data here although I do not think they help us very much. He has an anemia, a normal serum protein but you will notice a very marked reversal of the albumin globulin ratio which has been reported in severe liver disease in human beings and in experimental animals whose livers have been damaged by various means. The fact that he showed urobilinogen in the urine merely indicates liver damage and is not diagnostic of any particular type of liver disease. Surprisingly enough the fat tolerance curve which I

take it was done by Dr. Jones—I do not know anyone else around here who does this sort of thing—is surprisingly normal except for the high initial fatty acid level. The shape of the curve is essentially normal. Usually in severe liver disease the fatty acids are depressed below the fasting level within a half hour after subcutaneous adrenalin. I hope Dr. Jones will say more about that later. On the whole, the laboratory work does not help us very much and leaves us with our original clinical impression that this patient died with cirrhosis of the liver, probably the result of subacute yellow atrophy and he will exhibit a small nodular liver and an enlarged spleen. I think the liver will be small, although six months before he died it was felt two fingerbreadths below the costal margin. Some time ago I looked up a good many of these cases of acute and subacute yellow atrophy, where the liver had been felt clinically, and found that at postmortem the liver was very much shrunken. I think that probably will be the case in this patient. I cannot exclude a cirrhosis due to a diffuse intrahepatic lithiasis, although that is very improbable.

Assuming for the moment that he did die of cirrhosis of the liver of some infectious or toxic type, why did the diabetes disappear as the liver disease progressed? While there are certain patients with diabetes in whom the diabetes later disappears spontaneously for some unexplained reason, it is very uncommon, although a number of cases have been reported. We have learned in the past few years from the work of Houssay and of Long that pancreatic diabetes in experimental animals can be alleviated or cured by lesions of the pituitary or adrenals. In this case we have no evidence of disease in either the pituitary or adrenals. There also have been cases reported of improvement in diabetes with progressive cirrhosis of the liver. To be sure those cases are very unusual and quite rare but it is, nevertheless, a recognized clinical entity. I looked this question up a short time ago and found that the first one to report any such phenomenon was Claude Bernard in 1877. No further cases were reported until 1930, when Bordley at Johns Hopkins reported another case. Bordley in commenting on his case, whom Dr. Joslin had seen, quotes Dr. Joslin as saying that in his experience diabetes had never disappeared after the onset of cirrhosis of the liver of which he had seen several cases. Since that time several other cases have been reported of very severe diabetes requiring as much as one hundred units of insulin daily, the diabetes subsequently subsiding as the liver disease progressed and the patients finally dying in hypoglycemia. Why that takes place, I do not know, and there is no adequate explanation for it. One would think, believing what we are told about the physiology of the

liver, that the reverse ought to take place. In other words as the liver becomes progressively damaged its ability to store carbohydrates becomes impaired. As a matter of fact we use that glycogen storing power as a test for liver function. The levulose and lactose tolerance tests depend on the ability of the liver to transform and store this sugar as glycogen. One would therefore expect that if any change occurred in the glycogen storing function of a damaged liver it would be expressed in an inability to convert glucose into glycogen and store it with a consequent hyperglycemia and glycosuria. But strangely enough in this case we have the peculiar phenomenon of diabetes disappearing with progressive liver disease. Experimentally and clinically one can find arguments to support either side of the question. There are a fair number of cases in the literature of severe liver damage most of them due to metastatic malignancy with practically complete liver obliteration in which the patients die in spontaneous and severe hypoglycemia and in which hypoglycemic attacks precede death for some time. We all are acquainted with Mann's original work on dogs in whom hepatectomy resulted in death from hypoglycemia unless glucose was administered. Nevertheless recent work by Mann on hepatectomized dogs reveals that when their glucose tolerance curves were done they were diabetic in nature which is quite at variance and does not seem to jibe with a hypoglycemic death. The patient under discussion reveals an increased glucose tolerance test in the curve here. Other work done on animals whose livers were damaged by various toxins showed very variable results upon the glucose tolerance when the tests were done at different periods. Sometimes they will have an increased carbohydrate tolerance and at others it will be decreased. There seems to be no relationship between the degree of liver damage and the shape of the curve. As you will probably gather the whole question is quite a confusing one. This patient, however, probably represents one of those rare and unusual cases of diabetes disappearing with progressive liver disease of which there are only five or six cases in the entire literature.

Just one word about his final episode here. It has been my impression in seeing some of these patients that if they die primarily of the liver disease they are sick for a fairly long time before. This patient was comparatively well and died within a few days. I believe the chances are that he had some terminal acute episode taking place which turned the balance and caused him to die. I do not think he died primarily of his liver disease. He had some contributing factor toward the end. What that may be, would be sheer speculation, because we are told absolutely nothing about the way

he looked or the manner of his death but I want to hazard a guess because of several patients I have seen with this picture. It is perhaps a little foolhardy but I have seen three patients with severe progressive liver damage who came to the hospital and died within a few days after being comparatively well for a long time. One had a diffuse pneumonia and the other two severe renal disease. Whether this patient had one or the other of these two terminal events I cannot say, but I believe something of that nature will be found.

DR. CHESTER M. JONES I saw this patient for Dr. Fish in 1934 and he then had perfectly obvious disease of the liver. The question was what kind I think it was no more clear at that time than it is now why the diabetes faded out of the picture. I can only put that question to Dr. Root of the Deaconess Hospital. At one time the patient had a perfectly definite and severe diabetes which subsequently disappeared. I have no explanation why it disappeared.

I think Dr. Krane is absolutely right in saying the laboratory tests did not help us a bit. I think that is important to remember. In most instances we make a diagnosis of liver disease and confirm it by laboratory methods rather than make the diagnosis by laboratory tests alone. It is of some interest that the laboratory tests for the most part showed a serious disturbance of liver function but in this case showed no abnormal response to adrenalin as far as the blood fatty acids were concerned. I would have expected in this case to see a definite failure to rise in the fatty acid of the plasma after adrenalin, not a perfectly normal response.

As far as the diagnosis is concerned my impression at the time was biliary cirrhosis. All such patients tolerate infection very poorly and this patient died from a terminal infection as do most of them.

There is one other point of some interest. These patients with biliary cirrhosis frequently have attacks that simulate gall stone colic, with right upper quadrant pain, tenderness, fever, chills and jaundice. The pain sometimes is so severe that the surgeon is justified in exploring expecting to find gallstones. At exploration one finds nothing but hypertrophic biliary cirrhosis. I would like to know what Dr Root has to say about the case.

Da Howard F Roor This patient is a most interesting case and arouses a variety of speculative thoughts. When the patient was first seen in 1928 neither spleen nor liver could be palpated. In 1930 my note on his record was somewhat surprising. Both the liver and spleen were felt. The liver was felt two fingerbreadths and the spleen descended with respiration from five to six centimeters by actual measurement.

below the costal margin. He certainly had changed in the two years. The diabetes antedated whatever the process was that produced such a change in the liver and spleen. The urine and stools consistently contained bile. One of the reasons we made limited x-ray studies at the Deaconess Hospital at that time was that we really did not think there was any chance that the patient had gallbladder disease and we were interested to see what the outline of the duodenum might be around the head of the pancreas. The disappearance of the diabetes interests me now because at the moment at the Deaconess Hospital we are studying a girl twenty years of age who has had severe diabetes twelve years requiring fifty units of insulin daily. In the last six months suddenly she has changed so that she has severe hypoglycemic attacks without taking any insulin whatever. Her liver is palpable and enlarged. One case that was not mentioned, reported from the Mayo Clinic* is that of a woman aged thirty-six at onset of typical diabetes. At forty-three she came to the clinic and was then resistant to insulin, taking five hundred to six hundred units a day. In 1931 she gradually became so sensitive to insulin that it had to be omitted. Even then she had without insulin severe attacks of spontaneous hypoglycemia during which she was unconscious for hours. By 1933 these attacks had become so serious that she was operated upon and a liver in which fatty metamorphosis was the chief feature of the pathological examination was found. She was then started on treatment with betanin on the assumption that betanin might reduce the fatty deposits. Within a week I have learned that she is now once again a diabetic, having gone for a period of two years with practical disappearance of diabetes.

Then I was interested very much in the adrenalin test because in this girl under observation the blood sugar fell from under 160 to 70 milligrams after receiving half a cubic centimeter of adrenalin. After ergotamine it also fell from 90 to 20 milligrams per 100 cubic centimeters. The glucose tolerance test varies greatly with the conditions of glycogen storage. I should suppose that this patient had a progressive cirrhosis of the liver probably not haemochromatosis. I should suppose that it was a chronic cirrhosis with probably some terminal event of which we have few data. I do not know whether as a terminal event the infection produced return of the diabetes.

CLINICAL DIAGNOSIS

Cirrhosis of the liver
Diabetes

Cirrhosis of the liver, toxic

Ascites

Pyelonephritis

Miliary abscesses of the kidneys

Splénomegaly

PATHOLOGIC DISCUSSION

DR TRACY B MALLORY This case was followed over a four-year period by Dr Fish and he himself eventually did a postmortem examination in the patient's home. We have his notes and he sent in tissues for examination. He found marked atrophic cirrhosis of the liver with a very coarsely nodular liver. The spleen was enlarged. The gallbladder and pancreas were negative. The pancreas was grossly negative and the kidneys were swollen to about twice the normal size. These were the significant findings. The enlargement of the kidneys proved to be a severe diffuse infection associated with multiple abscesses and that undoubtedly was the immediate cause of death. The liver looks like a typical post acute yellow atrophy cirrhosis. There is no suggestion of proliferation of the bile ducts and no marked degree of lymphocytic infiltration of the portal areas such as one would expect with biliary cirrhosis. The pancreas as far as one can make out from a couple of sections is within normal limits. Certainly there is no hemochromatosis.

This is the first case that we have seen here of this syndrome of disappearance of diabetes in association with cirrhosis of the liver. For that reason we have all been tremendously interested in it. In regard to the differential diagnosis of the type of liver disease, I was in agreement with Dr Kranes rather than Dr Jones. It seemed to me the very much enlarged spleen and especially the leukopenia were against biliary cirrhosis. Moreover I think a point that we often forget is that there is a stage in the acute hepatitis that leads to atrophy, a stage often of pretty long duration, in which the liver is quite large.

CASE 22262

PRESENTATION OF CASE

A fifty year old native male was admitted complaining of abdominal pain and vomiting.

The patient at the time of admission was too ill to warrant a very detailed history. Two years before entry he began to have irregular attacks of vomiting without relation to meals. Occasionally cramp-like pains in the lower abdo-

men were associated with the emesis. He noted increasing constipation and had lost over fifty pounds during the two-year period. There were no tarry stools or coffee grounds vomitus. A gastrointestinal x-ray series done about eight months before entry was said to show evidence of adhesions.

Seventeen years before admission the patient was operated upon for a perforated appendix.

Physical examination showed a well developed and nourished pallid man appearing older than his stated age. There was a sour odor to his breath and some dried vomitus was noted upon his lips. The tongue was dry. The pupils were pin-point in size, evidently resultant upon a previously administered sedative, and reacted sluggishly to light. The lungs were clear. The heart was not enlarged and its sounds were regular. The pulse volume was poor. The blood pressure was 78/58. The abdomen was scaphoid and the upper border of liver dullness was at the fifth rib. The free edge was rounded and extended about three fingerbreadths beneath the costal margin. The descending colon was palpable and there was a questionable mass in the left lower quadrant just beneath the level of the anterior superior iliac spine. Another questionable mass was noted in the epigastrium. Rectal examination revealed the sphincter to be very tight with a sharp, smooth edge.

The temperature was 97°, the pulse 85. The respirations were 15.

Examination of the urine showed a specific gravity of 1.018 and a slight trace of albumin. The sediment was negative. The blood showed a red cell count of 4,300,000 with a hemoglobin of 75 per cent. The white cell count was 6,300, 84 per cent polymorphonuclears. A stool examination was negative. A Hinton test was negative. The nonprotein nitrogen of the blood was 51 milligrams. The serum chlorides were equivalent to 74 cubic centimeters of N/10 sodium chloride. The serum protein was 6.3 grams per cent and the biomides 75 milligrams per cent.

A plain x-ray film of the abdomen showed gas filling the entire duodenum, which was markedly dilated. The dilatation ended abruptly in the region of the duodenojejunal flexure. There were no other abnormal gas shadows in the abdomen but the colon contained considerable gas. A barium enema flowed freely from the rectum to the cecum. It was necessary to use about twice the usual quantity of barium before filling of the cecum was obtained. The cecum was smooth in outline and no constant deformities were noted. After evacuation a large quantity of barium remained in the colon. A small quantity of barium was given by mouth and although examination was not adequate no gross deformity was noted in the stomach. The duodenum filled normally and remained filled.

throughout the examination. A point of obstruction was present at the duodenojejunal flexure. The duodenum was markedly dilated and its mucosa was thickened. The pyloric valve was not identified.

The patient was treated supportively with parenteral fluids and his blood pressure gradually rose to 130/75. The chlorides rose to 96 and on the third hospital day a laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR. MARSHALL K. BARTLETT. The essential features of this history are increasing constipation and a loss of over fifty pounds in weight during a two year period associated with irregular attacks of vomiting and low abdominal pain in a man of fifty terminating in an acute episode which brings the patient to the hospital. The duration of the acute attack is not given but he was evidently very ill on admission.

The explanation for this train of symptoms could best be found in a partial or intermittent obstruction to the lumen of the intestinal tract which has recently become more or less complete. Pain has not apparently been a very prominent symptom and no exact description of his pain is available. All we know is that it was low in the abdomen, which would suggest an obstruction of the lower bowel rather than a higher lesion.

That a gastrointestinal x-ray done eight months before entry is said to have shown evidence of adhesions does not help me particularly.

The possibility that there is some relation between the present symptoms and the operation for appendicitis with perforation seventeen years ago must be kept in mind but it does not seem likely that a band or adhesions would be dormant for fifteen years and then give symptoms of intermittent obstruction for two years, ending in an acute episode. I am inclined to conclude that the operation for appendicitis has nothing to do with his present symptoms.

The physical examination gives us some faint clues toward localizing this man's disease and much evidence as to the seriousness of his general condition. He is evidently much dehydrated, undoubtedly the result of prolonged vomiting. Questionable masses are noted in the left lower quadrant and in the epigastrium. This does not help me particularly as it has been my experience that questionable masses are usually not confirmed at operation. The scaphoid contour of the abdomen, however, seems to me to be very important. If this man has intestinal obstruction we are forced to conclude that it is a high obstruction. If the point of obstruction were in the lower small bowel or colon we would certainly expect to find some

abdominal distention. The statement that the anal sphincter is tight with a sharp smooth edge does not seem significant.

The urine is normal except for a slight trace of albumin and examination of the blood shows only a slight degree of anemia. It would be my impression that the dehydrated condition with consequent concentration of the blood, accounts for the red cell count and hemoglobin being so nearly normal. It would be interesting to know what these figures were after the dehydration had been corrected. One stool examination shows no evidence of bleeding into the intestinal tract. The moderate elevation of non-protein nitrogen in the blood seems consistent with the patient's dehydrated state and the serum protein is within normal limits. The reduction of serum chlorides indicates the electrolyte loss which this patient has sustained by prolonged vomiting. A serum bromide determination of seventy-five milligrams per cent suggests that he has been getting bromides but is well below the usual toxic level. Since the serum bromides and chlorides are reciprocal, this rise in bromide would seem less significant in the presence of a reduction in chlorides than it would be if the latter were normal.

The x-rays in this case are extremely interesting and give us our only real clue to the exact site of the obstruction. The plain film shows a dilated and gas-filled duodenum, the dilatation ending abruptly at the duodenojejunal junction. The barium enema seems to be essentially normal although the colon emptied poorly. Barium by mouth confirms the finding of obstruction at the duodenojejunal flexure with dilatation of the duodenum.

Since all available evidence points to an obstruction at the duodenojejunal junction, let us consider the possible causes of obstruction at this point. It might be due to extrinsic pressure, as from a kink, band or tumor outside the bowel or to a stricture or neoplasm in the lumen of the intestine, either benign or malignant.

If due to a kink or band either congenital or acquired, as a result of his previous operation, it seems unreasonable for such a mechanism to give no symptoms for many years then intermittent symptoms and finally complete obstruction. Likewise it would seem unlikely that a tumor outside the bowel, such as a mesenteric or pancreatic cyst, would cause enough pressure to give obstruction until it had reached sufficient size to be more than a questionable mass in the epigastrium on physical examination. That a malignant tumor of the body of the pancreas could cause obstruction at the duodenojejunal flexure by direct extension is a possibility and I do not see that it can be ruled out.

It seems more likely, however, that the obstructive process is in the bowel itself. A stric-

true traumatic or inflammatory, is a theoretical possibility but would be exceedingly uncommon and would not, I believe, be likely to cause complete obstruction. The most probable cause, therefore, seems to be a neoplasm of the bowel, benign or malignant. This diagnosis would be strengthened by the presence of blood in the stools, as either a benign or malignant neoplasm would probably bleed from time to time. One negative stool examination does not seem to me to be enough to influence us unduly, however. It is unusual for benign growths of the small intestine to cause complete obstruction of the lumen while malignant disease typically does so, after a longer or shorter period of intermittent symptoms. The patient's age and marked weight loss also favor this choice. The enlarged liver with a rounded edge suggests the possibility of metastatic disease in the liver.

My conclusion would be that this man has an intestinal obstruction in the region of the duodenojejunal flexure, due to a malignant tumor.

CLINICAL DIAGNOSES

Carcinoma of the jejunum
Intestinal obstruction

DR MARSHALL K. BARTLETT'S DIAGNOSES

Intestinal obstruction
Carcinoma of the duodenojejunal flexure

ANATOMIC DIAGNOSES

Operation wounds: resection of carcinoma of the jejunum, jejunostomy
Operation scar: appendectomy
Intestinal obstruction, partial, lower ileum
Pulmonary embolism
Pulmonary infarct, right middle lobe
Pulmonary atelectasis, right lower lobe
Arteriosclerosis, slight

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY: This man's condition as the result of his long-standing obstruction was obviously desperate at the time of entry. Two days were spent in trying to get him into a state to stand operation by forcing intravenous fluids. An exploratory laparotomy was then performed. A constricting tumor growth was found in the jejunum beginning 3 centimeters beyond the ligament of Treitz and running for a distance of about five centimeters. The liver was free from metastases. By the time the situation could be evaluated the patient's condition had become progressively worse. It was impossible to obtain the blood pressure and he had several periods of apnea. With artificial

respiration plus oxygen and carbon dioxide and an intravenous injection of ten per cent glucose his condition improved enough so that it became possible to do a jejunostomy though any further operative procedure remained out of the question. Following this operation he improved slowly but continued to vomit frequently and it seemed probable that part of the feedings given through the jejunostomy opening were being regurgitated through the stomach. At the end of a week the situation remained at a standstill and it was decided to attempt a resection of the growth. This was carried out and the patient left the operating table in fair shape but the following day showed a feeble reaction and proceeded to go progressively downhill. No localizing signs appeared to indicate intestinal obstruction or peritonitis though both were considered fairly probable. He died six days after the second operation.

The specimen which was sent to us following the resection proved to be a segment of jejunum 25 centimeters in length near the upper end of which was a firm annular growth which constricted the lumen to a diameter of less than three millimeters. The mucosa was irregularly granular in this area without frank ulceration and the tumor obviously extended into the muscularis but not quite to the serosa. Several small rather firm lymph nodes were found in the mesentery one of which only showed metastasis on microscopic examination. The tumor itself proved to be a fairly well differentiated adenocarcinoma which showed a slight tendency to mucoid degeneration.

The autopsy added comparatively little information of interest. There was a localized and probably not very significant degree of peritonitis. The small bowel was moderately distended down to the last three and a half feet, where it was kinked about an old fibrous band. The portion beyond the kink was completely collapsed. Further dissection of the mesenteric and retroperitoneal glands showed no evidences of metastases and no nodules were found in the liver. A moderate sized infarct five centimeters in diameter was discovered in the middle lobe of the right lung and an adherent embolus was found in the pulmonary artery leading to this area. The right lower lobe was atelectatic.

Cancers of the jejunum are of course relatively uncommon. We have had about six in the course of the last thirty years at this hospital. When we do see them they differ in no respect grossly or microscopically from cancers of the large bowel except in their location. In our experience benign tumors of the jejunum such as myomata have been quite as common as the malignant ones.

PREVENTION BY CHEMICAL MEANS OF INTRANASAL INFECTION WITH VIRUSES

OLITSKY and Cox¹ were the first investigators to report experiments which showed that treatment of the nasal mucous membranes with a chemical resulted in a very definite protection against subsequent intranasal infection with a virus. By spraying the nostrils of mice with 0.5 to 1.0 per cent solutions of tannic acid on three successive days, they were able to obtain 95 per cent protection against the intranasal implantation of equine encephalomyelitis virus on the following day. This protection lasted for about five days after the last treatment with tannic acid, but the percentage decreased sharply after the third day. They believed the effect to be local, for no protection was afforded against intracerebral inoculation of the virus.

More recent experiments at the National Institute of Health have established the fact that certain chemicals used in a similar way are effective against experimental encephalitis and

poliomyelitis. Armstrong and Harrison² and Armstrong³ have found that the intranasal instillation by an atomizer of 4 per cent sodium aluminum sulphate or of 0.64 per cent picric acid either alone or dissolved in a 0.5 per cent solution of sodium alum affords a high degree of protection against subsequent intranasal infection in mice with encephalitis virus (St. Louis type) and in monkeys with poliomyelitis virus and against intravenous infection in monkeys with poliomyelitis virus. Such protection is present at least four to seven days after the last chemical treatment. The chemical does not interfere with the development of immunity in mice against encephalitis virus. No general or local injurious effects were noted, even after sixteen applications of picric acid. Treatment with picric acid one or two days before or after infection does not make the animal more susceptible to the virus. They conclude that the effect is purely local, either rendering the mucous membrane less permeable or acting directly on the virus or both.

Lennette and Hudson⁴ have shown that severing the olfactory nerves of monkeys results in survival of all animals when inoculated intranasally or intravenously with an otherwise fatal dose of poliomyelitis virus. This confirms the belief that the olfactory tract is the usual, perhaps the only natural route of experimental infection. Although this may not be strictly analogous to the route of infection in human beings, the possibility of adapting the chemical treatment of the nasal mucous membranes to prophylactic treatment in human beings against infection with poliomyelitis virus appears attractive. Such a procedure would seem to be more reasonable than recent attempts to immunize with presumably dead virus and certainly safer than using living even though attenuated virus for the same purpose. Further more widespread use of this chemical treatment in epidemic areas should not demand unusual outlays for the personnel and equipment necessary for carrying out controlling and evaluating the method in a proper manner.

VACCINATION IN THE OLD LINE STATE

THE monthly publication of the Baltimore Health Department for April-May¹ contains a noteworthy lithographic reproduction of a series of parings of vaccinal reactions. They represent a careful selection of the standard types of reactions which may follow vaccination including eleven pictures of a primary

"take" in the Negro. Their preparation was supervised by the Health Department, and the Department of Art as Applied to Medicine in the Johns Hopkins Medical School. Accompanying these pictures are a dozen pages of equally excellent reading matter concerning the preparation and care of vaccine, the technique of its insertion, the standard reactions and other pertinent information.

Also contained therein are a few pages on the early history of vaccination in Maryland. Many New Englanders will be surprised to learn that Benjamin Waterhouse of Cambridge may have unknowingly raced with Dr. John Crawford of Baltimore in performing the first vaccinations on this continent. Crawford seems to have successfully vaccinated in the summer of 1800. He left no dated record, so the vaccination of Waterhouse's son on July 8, 1800, still holds priority in Massachusetts. Another Baltimore physician, Dr. James Smith, worked ardently and over a period of many years to secure the more universal adoption of vaccination. The endorsement of the Medical and Surgical Faculty of Maryland in 1802 is referred to as the first "official recognition and sanction of Jenner's great discovery by any American association of physicians." One wonders if it preceded or followed the Noddles Island experiment of the Boston Board of Health in the same year, when nineteen vaccinated children were not only housed and constantly exposed in the smallpox hospital for a period of twenty days, but were inoculated and reinoculated with variola in a vain attempt to give them the disease. It was thus that the Board of Health reached its unequivocal conclusion that "cowpox is a complete security against the smallpox."

Vaccination in Massachusetts is stated to have been "stubbornly opposed by the profession for years." To be sure, we had our difficulties but if our friends on the Chesapeake think that it was stubborn opposition they should have been here in 1721, when Zabdiel Boylston began to inoculate for smallpox. Dr. Boylston was threatened with lynching, was the target of a bomb which fortunately failed to explode, and could not go upon the street or visit his patients except in darkness and by stealth. That was probably the beginning of what is now known as "medical liberty" and it almost certainly is the spirit which forced Massachusetts to enact legislation in 1809 ordering every town where no board of health existed to appoint three or more persons to supervise vaccination. It also led us to pass (and later to enforce) our compulsory vaccination law, and in 1905 to test its validity in the Supreme Court of the United States. All this may have happened ac-

tually on account of the Divine Discontent of our forefathers.

THIS WEEK'S ISSUE

CONTAINS articles by the following named authors

COHEN, SIDNEY SLATER, A.B., M.D. Harvard University Medical School 1930. Junior Assistant Surgeon to the Surgical Service, and Member of the Vascular Clinic, Beth Israel Hospital. Address: 475 Commonwealth Avenue, Boston, Mass. Associated with him is

BARRON, MAURICE E., A.B., M.D. Tufts College Medical School 1914. F.A.C.S. Assistant Professor of Surgery, Tufts College Medical School. Visiting Surgeon, Beth Israel Hospital. Address: 475 Commonwealth Avenue, Boston, Mass. Their subject is Thrombo Angitis Obliterans with Special Reference to Its Abdominal Manifestations. Page 1275.

WOOLNER, WARD, M.D. University of Toronto Faculty of Medicine 1903. Medical Officer of Health, Ayr, Ontario. His subject is Rural Health Problems, the Problems Themselves, and Their Control. Page 1305. Address: Ayr, Ontario.

THOMAS, JACKSON M., B.S., M.D. Emory University School of Medicine 1926. Chief Medical Officer, Boston Psychopathic Hospital. Instructor in Psychiatry, Harvard University Medical School. His subject is Progress in Psychiatry for 1935. Page 1309. Address: 74 Fenwood Road, Boston, Mass.

MISCELLANY

DR. ROBERT T. MONROE BECOMES A MEMBER OF THE STAFF OF THE PETER BENT BRIGHAM HOSPITAL

Dr. Robert T. Monroe, A.B., University of Michigan, 1918 and M.D. 1924, Associate in Medicine at the Harvard Medical School, has been appointed Physician to the Peter Bent Brigham Hospital, effective September 1 to succeed Dr. Reginald Fitz.

He served as medical house officer at the Peter Bent Brigham Hospital from July 1, 1924 to November 1, 1925, as Assistant Resident Physician from November 1, 1925 to September 1, 1926, as Junior Associate in Medicine from September 1, 1926 to December 8, 1932 and as Associate in Medicine from December 8, 1932 to date.

A CHANGE IN THE POSITION OF CITY PHYSICIAN OF NORTH ADAMS

Major William Johnson of North Adams, Massachusetts has appointed Dr. Vincent Paul Cummings to the position of city physician to succeed Dr. W. F. McGrath.

Dr. Cumming graduated from the McGill University Medical School in 1931 and is about thirty two years old

He is a Fellow of the Massachusetts Medical Society

AN ADDRESS BY DR. ALBERT M. SNELL

Dr. Albert M. Snell, head of a division in medicine at the New Clinic, gave an address before the staff of St. Vincent Hospital June 5 at the hospital. The Worcester District Medical Society was invited and one hundred and fifty attended. His subject was "The Diagnosis of Conditions Associated with Jaundice." There were discussions by the hospital staff.

A TESTIMONIAL DINNER

Grateful Atlantic City hotel men appreciative of the fact that the American Medical Association voted to hold its 1937 meeting in that city gave a testimonial dinner recently at the Hotel Traymore in honor of the four delegates from New Jersey and the Director of the great Atlantic City Convention Bureau, Albert Breen.

The delegates who were honored were Dr. Walt P. Conaway and Dr. Hilton S. Read of Atlantic City, Dr. John F. Hegerty of Newark, N. J. and Dr. E. R. Mulford of Burlington, N. J.

The object of the dinner to the delegates of the American Medical Association Convention was to honor the Medical Fraternity of the State.

DARKFIELD SERVICE FOR THE DIAGNOSIS OF PRIMARY SYPHILIS

The diagnosis of primary syphilis is a laboratory procedure. The appearance of the lesion and the patient's history may strongly suggest syphilis and yet a diagnosis of syphilis be erroneous. Conversely the most "insignificant" or atypical lesion may be the primary lesion of syphilis.

Although the more sensitive blood tests will frequently detect syphilis soon after the appearance of the primary lesion there is often a delay of several days or even two or three weeks before blood tests become positive. Delay in beginning treatment is dangerous to the patient because it seriously affects the prognosis and to the public because of the communicability of an untreated recent infection. Even the delay of waiting for the result of a blood test is to be avoided if possible although blood tests should always be done.

The darkfield examination of serum from the lesion for living spirochetes offers a method of immediate diagnosis. The examiner however must have had training and experience in the identification of the spirochete pallidum. The patient must

be sent to the physician who is to make the examination as living organisms must be seen, and several specimens may have to be examined

In order that the physicians of Massachusetts may be informed as to available darkfield diagnostic service, the State Department of Public Health publishes, herewith, a list of the physicians who have indicated to the Department that they are equipped, competent and willing to make darkfield examinations for syphilis

This service will be of the greatest usefulness if those who use it will be guided by the following suggestions

- 1 Make arrangements with the consultant physician or laboratory by telephone or in person, as to when the patient can be seen and as to the cost of the examination. The physicians and laboratories listed have agreed, with few exceptions, to adjust the fee to the ability of the patient to pay
- 2 If the patient is referred for diagnosis only, state so clearly, or both consultant and patient may assume that treatment also is to be provided by the consultant
- 3 Under no circumstances apply any treatment to the lesion, except saline compresses (see No 4), before the darkfield examination is made
- 4 If an ointment or other local treatment has already been applied, prescribe salt solution compresses for twelve to twenty-four hours before the darkfield examination is to be made
- 5 Under no circumstances give the patient any anti-syphilitic treatment until the darkfield examination and the diagnosis have been made. A single injection of an arsenical may cause all the spirochetes to disappear from the lesion
- 6 Do not depend upon the result of a darkfield examination of a lesion which is located *within* the mouth (on the tongue, tonsil, buccal membranes) for there are spirochetes in many mouths which are readily mistaken for the spirocheta pallida. A darkfield diagnosis may ordinarily be made of a chancre of the lip, however
- 7 Any genital lesion, however "insignificant", and any extragenital lesion, especially of the mouth, which does not heal promptly or which cannot be diagnosed absolutely as non-syphilitic, should be subjected to darkfield investigation

eye and ear infirmaries. He practiced in Ashburnham, Massachusetts several years before settling in Fitchburg and served as alderman in the last named city in 1906-1907.

He was a Fellow of the Massachusetts Medical Society until he retired in 1935 and had been a member of the American Institute of Homeopathy.

He was a past master of the Anrora Lodge A F & A. M. and had progressed through the various orders to become a 32nd degree Mason.

Dr Perkins is survived by his widow Mrs Edith (Prescott) Perkins a daughter Mrs A M Powell of Worcester Massachusetts, and two sisters.

FALLON—As the forms for this issue of the *Journal* were closing a notice of the death of Dr Michael F Fallon of Worcester on June 24 was received. A further notice will appear in the *Journal* of July 2.

OBITUARY

JAMES TATE MASON M.D.

It is with the deepest regret that the *Journal* records the death on June 20 at Seattle of Dr James Tate Mason, President of the American Medical Association.

Dr Mason was born in Virginia in 1882 and received his medical education at the University of Virginia, graduating in 1905. After practicing a few years in Philadelphia he moved to the West Coast and eventually settled in Seattle in 1909. As an eminent skillful and successful surgeon he founded and built up the Mason Clinic and the Virginia Mason Hospital was consulting surgeon for several large industrial companies and a member of many important medical societies.

During his incumbency of the position of President Elect of the American Medical Association Dr Mason visited Boston and was entertained by Dr Roger L Lee, Trustee of the Association and the officers of the Massachusetts Medical Society.

Although unable because of illness to attend the annual meeting of the American Medical Association at Kansas City this spring he was elected president *in absentia*. It is unfortunate that death should have come at the very height of Dr Mason's career and the *Journal* takes this opportunity of expressing its most sincere sympathy to his family and to the American Medical Association.

REPORTS OF MEETINGS

NEW ENGLAND PHYSICAL THERAPY SOCIETY

The adjourned Annual Meeting of the New England Physical Therapy Society was held at the Hotel Kimball Springfield on June 8 1936 directly following the program of the Section of Radiology and Physiotherapy of the Massachusetts Medical Society.

Arrangements were completed for the New England Physical Therapy Society to act as hosts to the

Academy of Physical Medicine when the latter organization holds its three-day Annual Meeting in Boston next October. This will be the Academy's first visit to Boston since 1930.

PETER BENT BRIGHAM HOSPITAL LECTURE

The first of a series of three lectures was delivered by Dr K. H. Gieritz, Surgeon-in-Chief in the Sabbatsberg Sjukhus Stockholm and Surgeon to the late Queen of Sweden on May 18 1936 in the Peter Bent Brigham Hospital where he is serving as Surgeon-in-Chief *pro tempore*. In introducing the speaker Dr Elliott C. Cutler reminded the audience of the admirable place held by Sweden in providing good medical care for all the people from both the scientific and social viewpoints. Dr Gieritz spoke on "Twenty Five Years Experience in the Treatment of Peritonitis."

The cases analyzed by him in studying peritonitis included all instances of the disease treated under his direction as Senior Surgeon between 1910 and 1934 except for pelvic peritonitis in women. Peritonitis is not a uniform and constant disease the manifold character of reactions in various individuals combined with the diverse origins of the condition produces a variety of clinical forms. The really effective way of combating peritonitis is to prevent it by eradicating the cause before the process has gone beyond the stage where it is irreversible. As a warning sign abdominal pain of a generally severe nature stands first because if it is heeded promptly the cause can be removed in time to check the spread of infection. Unfortunately there exist certain rare forms typified by pancreatitis and acute purulent peritonitis of undetermined origin where one cannot remedy the cause.

Misinterpretation of reported statistics in this condition may be blamed on several factors the first of which is a failure to distinguish the stage of the progressing infection. In the beginning the peritoneal cavity is filled by a free effusion spreading from a local source of infection as a seropurulent or purulent exudate. After the second or third day the infection tends to become walled off and local encapsulated abscesses not communicating with the general peritoneal cavity are formed. In the case of appendicitis, the position of the appendix the presence of adhesions, and other local factors may be influential in determining the course of the process. While cases which heal often present residual abscesses the exudate may all be reabsorbed during recovery.

Even when an early operation is performed it is impossible to tell whether the result will be reabsorption, encapsulation or general peritonitis. The free diffuse type shows a decreasing tendency to reversibility up until forty-eight hours after which general peritonitis is the rule. Early operations have a low mortality require no drainage and heal without difficulty while delayed surgery entails a considerable mortality long incisions with drainage the removal of encapsulated pus and the possibility of ileus. An estimate of the peritoneal in

vovement is preferred to a statement of whether the appendix has perforated. In generalized purulent peritonitis better results are found from small incisions, little handling of the bowel, and primary closure of the wound than from large incisions and aggressive measures.

A third point of disagreement arises from the comparison of late septic operations with those undertaken early for prophylaxis. Since the prophylactic operations must be as simple and nonirritating as possible, good diagnosis beforehand is essential to prevent unnecessary exploration. X-rays of the abdomen may prove very useful in determining the nature and extent of the trouble, and should be employed without delay. A midline incision for diffuse peritonitis should be made only for a definite reason, but a small exploratory incision over the appendix may be justified by the frequency of inflammation there.

Ileus associated with peritonitis is of two types, mechanical and paralytic. In recent and acute inflammations a limited part of the small intestine becomes a stiff and rigid tube, producing a mechanical obstacle to intestinal function. When the peritonitis becomes fibropurulent a toxic factor is added to the mechanical one, giving a paralytic or inhibited ileus. Whether a specific toxin exists is not certain, although the observation that the circulatory collapse occurring in intestinal obstruction is relieved by gastrostomy and recurs when the gastrostomy is closed suggests the activity of a toxic agent. The surgical treatment of ileus in the presence of peritonitis is none too satisfactory. In acute purulent peritonitis ileostomy proved useless, as all the patients died. Cecostomy is superfluous and may prove hazardous. Besides being easily performed and healing readily, gastrostomy relieves the fecal vomiting and allows fluids to be given, if the tube has been put through the pylorus into the duodenum. Dr. Giertz commented on the use of the Wangenstein tube only to say that his experience was not large enough to state whether this was as efficacious as gastrostomy.

In appendiceal peritonitis the mortality was 8.35 per cent, but if there was not more than seropurulent peritonitis locally it was 1 per cent or less. From routine leucocyte counts and sedimentation rates done on all appendicitis cases, it has been observed that acute gangrenous appendicitis presents a leucocytosis of 10,000 to 14,000 (rarely above 20,000) with a normal sedimentation rate in the first two days. If a low white cell count or a high sedimentation rate is discovered, a diagnosis of appendicitis is less likely to be made. Up until forty-eight hours the operation for appendicitis is considered easy, while after that it becomes serious and should be done only by an experienced surgeon. Primary closure of the wound is done routinely, if phlegmon of the abdominal wall develops, as it may do even in the absence of peritonitis, secondary drainage is instituted.

Residual abscesses are commonest in the pouch of

Douglas, and may also localize in the iliac fossae and under the diaphragm. In the latter location they may arise after gallbladder disease, perforated peptic ulcer, gunshot wounds, tumor, and the like, although appendicitis is the usual cause.

Perforated peptic ulcer demands early operation, to prevent the development of peritonitis. If the patient is in poor condition, the perforation is more than four hours old, or the operator is inexperienced, the best results will follow a simple closure of the perforation and a gastrostomy. More extensive procedures, like gastroenterostomy and resection, are not justified by their results.

The gangrenous gallbladder rarely produces a purulent peritonitis, of a comparatively mild sort, which almost never results in ileus. Death occurs as a result of the original disease, not from peritonitis.

Pneumococcal peritonitis occurred only three times in the series, although cases of empyema of the peritoneum and umbilical abscess caused by this organism were observed.

Certain cases of acute generalized purulent peritonitis disclosed no local cause at operation or necropsy. These cases ought always to be explored with appendicitis in mind, if the appendix is normal it may be left in, to minimize trauma to the already infected peritoneum. In twenty-five years three cases of gangrenous appendicitis missed early operation because the diagnosis was not made, and ended fatally when the operation was performed later.

An acute onset of scarlet fever in children with severe abdominal pain may simulate appendicitis; a serious streptococcal peritonitis is likely if operation is done.

In closing, Dr. Giertz reiterated the importance of accurate diagnosis and early operation in reducing the mortality from acute abdominal conditions and emphasized the necessity of educating the public with regard to the great risk of delay in such cases.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK
BEGINNING MONDAY, JUNE 29, 1936

Tuesday, June 30—

- 9 A.M. Massachusetts General Hospital Orthopedic-Poliomyelitis Clinic—Out-Patient Department
- 9 A.M. Massachusetts General Hospital Thoracic Clinic

Wednesday, July 1—

- 4 P.M. Massachusetts General Hospital X-Ray Conference

Thursday, July 2—

BOOK REVIEWS

Endocrinologie Noël Piessinger 152 pp Paris Masson et Cie 20 fr

This small volume is one of a series of brochures which is being published dealing with the various phases and specialties of medicine Psychiatry gynecology the treatment of syphilis dermatology neurology and the digestive disorders have been among the subjects covered thus far Short volumes on radiotherapy and the disorders of nutrition are in preparation

The present book is written by an authority on endocrinology and is intended to present in a brief simple yet embracing manner the essentials of this branch The author takes up the glands of internal secretion from the standpoint of their normal and altered physiology their pathology and accompanying physical changes and the treatment of them Care is taken to limit the text to the consideration of only those glands which contain or produce hormones The subject of endocrinology is indeed an extensive one Nevertheless the author manages in this relatively small volume to accomplish the purpose previously referred to The illustrations though small in number are excellent The book is highly recommended to the medical student. It can in addition be utilized with benefit by the physician desiring a quick review of or an introduction to the very interesting subject of endocrinology

An Introduction to Surgery Rutherford Morison and Charles F M Saint Third Edition 367 pp Baltimore William Wood & Company \$5.00

The title of the book indicates its purpose It is designed for students beginning their surgical studies. In setting forth the signs and symptoms of surgical diseases its basis is pathological—an exposition of the reaction of various tissues to various insults We read in the introduction Nature alone can heal but often requires help In order that the help which surgery can give may be applied correctly and to the best advantage we must understand her methods and seek to imitate them Although to two such experienced surgeons as the authors the temptations to discourse on operative practice may have been difficult to submerge, they have steadfastly held to their primary objective The volume is more than one in surgical pathology It instructs the student not only in nature's immediate reaction to various insults but also in her methods of repair The twenty-two chapters proceed in good order gradually developing the student's knowledge so that by the twenty-first chapter he is prepared for a consideration of the Indications for Operations and in the twenty-second chapter for Pathological Conditions Illustrating the Application of the Principles of Surgery

The text is terse in places little more than a typical outline. This fact and the two hundred illustrations with a good index enhance its value as a reference book for students and teachers of

the fundamentals of surgery. In a volume of this scope there are naturally certain moot matters which are set forth in too didactic a manner. The reviewer regards the work favorably and believes that others than those who are starting their surgical studies may profit greatly by its perusal.

Convalescent Care in Great Britain Elizabeth Greene Gardiner 163 pp Chicago The University of Chicago Press \$1.50

This book is the result of a survey made in 1930 of the hospitals and rest houses in England, Wales and Scotland especially designed for convalescent care. There is nothing in this country which quite compares with the service offered in Great Britain, except possibly in the region of New York City. It is felt that lack of facilities for the convalescent care of patients is one of the outstanding weaknesses of American medicine. The survey is thus published with the idea that similar service may ultimately be offered to patients in the United States. The book is important in relation to the social aspects of medicine. The survey seems to have been adequately done and the report full.

A Textbook of Roentgenology The Roentgen Ray in Diagnosis and Treatment Bede J. Michael Harrison 826 pp Baltimore William Wood & Company \$10.00

The method of presentation is rather unusual for a book on Radiology. There are 826 pages with only 238 illustrations. No reference to the current literature is made, either in the text or in the form of a bibliography. In the Preface the Author gives a list of standard textbooks to which he has referred, and he definitely states that he has planned the book for students and general practitioners rather than for specialists.

On the whole he has succeeded in producing a rather unique book which accomplishes very well the object for which it was written. Advice to the student and practitioner in the Introduction is particularly good and worth quoting even in a review such as this.

'So far it does not appear to have been accepted as a basic fact in medical practice that consultation between the roentgenologist and the clinician should take place before any roentgenological examination other than the very simplest is undertaken. It must be remembered that the examination and interpretation of roentgenograms are directly correlated with the technique of their production, and that it may be very difficult to analyze a roentgenogram satisfactorily unless one is capable of analyzing the technique which was employed in producing it. Hitherto overmuch stress has been laid on the promiscuous viewing of roentgenograms in wards and operating theatres, etc., and insufficient stress

has been laid on the proper consultation prior and subsequent to the roentgenological investigation.

In discussing the various conditions in which the x-rays may be used either as a diagnostic aid or a therapeutic procedure, the Author has preceded each subject with a discussion of the underlying pathology. The roentgen findings are then presented briefly with a short discussion of the roentgen treatment when this therapeutic procedure is indicated.

Controversial procedures have been avoided and the presentation is clear and concise. No extravagant claims are made. Recent advances in the field of roentgenology and therapeutics are included. The book contains an excellent chapter on Radio-Physiology and Biology, and one on Dangers and Protection.

It is well printed and the illustrations, although limited, are well selected. It should prove a satisfactory textbook for students and practitioners, and is worthwhile for the experienced roentgenologist.

A Textbook of Obstetrics. For Students and Practitioners Frederick C. Irving 558 pp New York The Macmillan Company \$6.00

In his introduction the author states that this book is an amplification of the lectures used for a number of years in teaching the second, third and fourth year students at the Harvard Medical School, and represents the policies and practices at the Boston Lying-in Hospital. The book is divided into two parts, Part I containing the material on normal obstetrics, and Part II that on abnormal obstetrics.

The author covers the whole subject satisfactorily and in a clear and concise manner. The procedures that he advises are carefully described and are those of safe, conservative obstetrics. If all practitioners carefully followed the advice that the author has laid down, a tremendous improvement in obstetrics would follow.

At times the author assumes that students and practitioners know more than they really do, and he omits details which in a textbook should be made absolutely clear. There is no warning to the student about the necessity of carefully watching cases which have developed puerperal insanity. There is no description of the postoperative care in Cesarean section. Neither is there any reference to the use of ether in a breech delivery.

The author's advice to insert a Voorhees' bag in all cases of ruptured membranes where labor does not ensue within forty-eight hours is questionable, and he makes no clear distinction between a contraction ring and a retraction ring. He advises a very conservative stand in the treatment of eclampsia. In connection with plasmapheresis, it would be interesting to know the number of cases in which this procedure was used alone, or whether it was used only as an adjuvant to other procedures in the treatment of eclampsia, and what results were ob-

ained. In the treatment of pre-eclampsia as advised by the author he apparently condemns the use of Caesarean section in those cases where improvement does not take place after treatment, and emptying the uterus is thought necessary. It is an important admission on the author's part, that regardless of the treatment employed, the mildness or severity of the individual case of eclampsia is in most instances the determining factor between recovery and death.

The illustrations on the whole are well chosen. They are reproduced with varying degrees of excellence. The similarity of the drawings on the technique of the use of forceps to those of the well known work of Farabent and Varnier is striking and they are without question among the best in the book clearly explaining the application of forceps in the various positions.

At the end of each chapter are well-chosen references for the student's use.

The book is a well-defined exposition of obstetrics giving the student an excellent understanding of not least one method of managing his cases.

The Single Woman and Her Emotional Problems
Laura Hutton, 150 pp. Baltimore: William Wood & Company \$2.00

Although excellent in parts this little book is distressingly inadequate. Many will disagree with the Freudian explanations and will prefer to apply more generally the statement that the author makes regarding sexual inversion—At the present time then all theories must be tentative—Although stressing the physiological innocuousness of masturbation—by oneself or by another woman—may well be worth while and a great source of relief to many worried women the taboo which makes sexual relations between women in Sweden and Germany illegal cannot be disregarded. Strangely enough the author does not discuss the origin and merits of this taboo.

The author makes no mention of the value of exercise diet or other means of lessening sex drive—thereby greatly lessening the adequacy and usefulness of this book.

The Specificity of Serological Reactions. Karl Landsteiner 178 pp. Springfield and Baltimore
Charles C Thomas \$4.00

This is an excellent monograph concerning a very specialized subject. Originally published in German this second edition which is the first English edition brings the subject matter up to date.

After the introductory remarks the five chapters cover in turn the serological specificity of proteins of the specificity of all antigens, the specificity of antibodies artificial conjugated antigens, including serological reactions with simple chemical compounds, and chemical investigations on specific cell substances including carbohydrates and lipids.

As one would expect, the author presents the different aspects of this complicated branch of immunology clearly and in logical sequence. There are many explanatory footnotes and the majority of these, as well as the text refer to approximately 1,300 titles in the bibliography. In addition the author provides a list of textbooks reviews and monographs covering the general aspects of serology and immunology and the more specialized considerations of specificity. The book is beautifully printed on good paper and is well bound.

Though hardly to be recommended to the busy practitioner unless he happens to be interested in the allergic manifestations of disease, the book should be of inestimable value to all concerned with teaching and with investigative work in serology and immunology.

A Textbook of Surgery by American Authors. Edited by Frederick Christopher 1633 pp. Philadelphia and London: W B Saunders Company \$10.00

Christopher's Textbook of Surgery is a long text book (1567 pages plus 40 pages of fine print index). The individual sections have been written by a large group of the best surgeons and teachers of surgery in the country. The choice of contributors for each subject is on the whole excellent. The book is well made well printed, and well illustrated. Like any book made up in this way the subject matter is a little uneven but most of the articles are very up to date and contain the best practice thought and developments of the last few years. It is certainly on a par with the best of other modern textbooks in this field except, perhaps, for the unevenness of the articles mentioned above. On the whole it attempts to go into a little more detail in operative technique than some of the shorter textbooks.

Of course an individual reviewer can find fault with almost any book if he looks hard enough. The most glaring statement noticed here was the recommendation in the section on radiological examination that the use of Thorotrast intravenously is good practice for demonstrating certain diseases of the liver and spleen. A very large number of roentgenologists and other physicians would not agree with this because of the danger of late harmful results from this radioactive substance. Again in the section on tumors of the breast it is indicated that transfusion should be available at the completion of all radical breast operations. The reviewer believes that routine transfusion should not only be available but given in such operations as resection of the stomach and intestines and many others but has never found shock of serious degree to follow radical mastectomy in the great bulk of such cases. In this section also which is a very full one one would think that a little space might have been saved in the anatomical description of the intra-thoracic lymph nodes which cannot be reached any way and a little more attention given to a discussion of which cases should have radical surgery and which should have radiation or other forms of

treatment There is no statement in this section as to the prognosis following treatment at different stages of the disease or in relation to different types of pathology

In spite of occasional slips such as these this book should be extremely valuable to the student, the practitioner and even to the master surgeon

The Phenomena of Life A Radio-Electric Interpretation George Crile 379 pp New York W W Norton & Company, Inc \$3 50

'The Phenomena of Life' is another in the series of books written by George Crile to explain in popular form his thoughts and beliefs in physiology It is arranged in the form of an exposition of the development of thought and knowledge concerning surgical shock as it has come to him in his life time In the chapters of the book on the most recent developments he gives a very loose interpretation of some of the newer ideas having to do with neurophysiology and especially with regard to processes of combustion and nervous impulses

So-called "popular science" of which this is a typical example, even if the author does not label it as such, may be "popular", but all too often it is not science

If the author were more rigorous in his reasoning and exposition, a book having to do with the subject at hand could be extremely valuable, not merely by stimulating thought along lines that really are new and important, but as a point of departure for further investigations As it is, it has some value to any reader well enough trained in the method of science to realize that his "proofs by analogy" are not scientific proofs, but are merely hypotheses that need investigation Taken in this way, that is, as the brilliant speculations of an extremely brilliant mind, and realizing that among these speculations there are probably a few among many that will be found to be important, the book is interesting

However there are many sections that any reader will be unable to understand because pseudoscience, not being logical, is not adapted to being understood by the logical mind The average reader will probably lose interest before finishing the book

Your Hay Fever Oren C Durham 264 pp Indianapolis and New York The Bobbs Merrill Company \$2 00

Whenever a real authority talks or writes about his particular subject, the words, whether spoken or written, command attention Dr Durham has devoted his full time and energy for many years to the study of pollen and now he presents the results, in a book which will appeal to every hay fever sufferer, and to his physician also

The story of hay fever which occupies the first half of the book is delightfully written How dramatic was the early development of our present

knowledge! Dr Bostock and Dr Blackley come life for us and it is almost painful to see how close they came to the facts as we know them today The account of their interesting experience almost begs the reader to look over the original works for himself

The second half of the book contains a variety of technical points about pollen—its structure, function, and particularly its distribution The common hay fever trees, grasses, and weeds are described briefly but sufficiently Simple maps, tables and a few illustrations amplify and summarize the text At the end is a short section on treatment written by Dr S M Feinberg in which the principles and objects of specific treatment are explained in a simple, clear fashion Technical details are given

The book can be recommended to anyone interested in hay fever

The Single, The Engaged, and The Married Man Chideckel 268 pp New York Eugenics Publishing Company \$2 50

It is difficult to see why this book was written or published Whatever of value it contains has already been written The style is poor and sometimes even illiterate The book also contains many misstatements of fact such as the following on page 238—"In a small percentage the male sperm is strongly alkaline and the vagina is weakly acidic. These marriages produce essentially only male children The reverse is also true that in other marriages weakly alkaline sperm are deposited in a strongly acid vagina and the result is that typically only girls are born", and on page 240 "So the ovary on each side has a sac, in the center of an egg, the sac ruptures and a yellow body, the corpus luteum, takes the place of the sac The yellow body, after it takes the place of the egg, grows, becomes large and exerts great pressure on the lining of the womb The womb lining has many blood vessels Because the yellow body, or corpus luteum, by becoming large gives off a hormone which presses these blood vessels, they rupture and bleed That bleeding is what causes the woman to menstruate"

The Eugenics Publishing Co, which puts out this book is responsible for the following: *Sane Sex Love, The Sex Side of Marriage, The Torch of America's Sex and Marriage Problems, Woman's Sex and Love Life, Sexual Truths*, and so forth, all at the same address The Book Collectors' Association holds forth Some of their productions are more racy The *Satyricon* of Petronius, *The Art of Bundling*, and so forth

The author has evidently had a considerable experience in sex problems of various kinds, his comments and handling of many of the problems seem reasonably valid but, when he claims to have cured 69.5 per cent of 200 cases of sterility, that his statistics and claims are open to considerable doubt.
